PROBLEMS IN RELATION TO THE HARD OF HEARING*

HORACE NEWHART, M.D., F.A.C.S.

Associate Professor of Oto-Laryngology,
University of Minnesota

Minneapolis

Under the above rather broad title it is our purpose to present a few facts in regard to the needs of the deafened as they concern the physician, particularly the general practitioner with his broad interest in human welfare.

A conservative estimate, based upon various sources, including statistics furnished by medical examinations in our public schools and the examinations of drafted men, discloses the fact that we have in the United States upwards of three million individuals of all ages whose hearing acuity has been so reduced as to prove a handicap in their educational progress, in their economic efficiency and in their capacity to enjoy normal social contact with their fellows. This estimate seems not unreasonable when one reads in the advertising pages of our popular journals the statement of a single manufacturer of an electrical apparatus to aid the deafened, that he has already sold more than 400,000 of his appliances; and he is but one of several makers of well known forms of ear phones, which only persons with a well advanced impairment can advantageously use.

It is conceded that by far the greater number of cases of deafness are preventable. Thus the situation, involving so large a number whose condition is practically as unfortunate as that of the blind, challenges the skill, active interest and intelligent efforts, not only of the otologist, but of the physician, the educator and the social service worker.

The problems of the deafened (in distinction

from deaf mutes or the congenitally deaf) may be grouped as: (1) those pertaining to the prophylaxis and treatment of all diseases which may result in impaired hearing; (2) those relating to the education and rehabilitation of the deafened; (3) those pertaining to the economic and social welfare of the hard of hearing.

Prophylaxis and Treatment.—After attempting to teach otology to undergraduate medical students for more than a decade, it is the writer's opinion that the fundamental need in the prevention of acquired deafness lies in a more thorough training of the medical student in this branch of medicine, whereby he would be better equipped to recognize and successfully treat those diseases which lead to impaired hearing. This demands that more time be devoted to this subject in our medical schools than is now accorded it. Properly equipped so as to be sufficiently skilled and interested in diseases of the ear, the general practitioner would be able to render as good service in this field as he gives in general surgery or internal medicine. That he is not adequately equipped is attested by his evident lack of enthusiastic interest in otology and by the impressive number of our failures to prevent avoidable cases of defective hearing. It should never be forgotten that the majority of patients are not in the habit of consulting a specially trained otologist for the seeming insignificant maladies which so often lead in time to irreparable loss of hearing. In this matter, however, the public should be educated by the family physician to neglect no ear symptom or any diseased condition of the upper respiratory tract which might affect the hearing.

Other important points in the prevention of deafness are: (1) the regular routine examination at frequent intervals of all individuals as to the acuity of their hearing and (2) the earliest possible removal of all discoverable pathological factors which might cause ear disease. Children of school age in our cities, to a large extent, receive this attention, but the benefits of such examinations

*Read before the annual meeting of the Minnesota State Medical Association, St. Paul, October, 1923.

and treatments must be extended to individuals of all ages and in all communities.

The problem of the proper treatment of one who has become materially deafened calls for a considerable degree of skill, judgment, tactfulness and consideration. Whatever local treatment is contemplated in chronic cases should always be based upon the results of a painstaking otological examination. Any physician who arbitrarily advises a patient who is hard of hearing that nothing can be done to help his condition, without having himself made a careful otological examination or having had such examination made by a competent otologist, commits an act of gross unfairness to the afflicted party and discredits the ideals and skill of other members of his chosen profession. Yet, today we see among the hard of hearing numerous examples of almost criminal neglect on the part of parents, of the patients themselves or of their previous medical advisors. This neglect is rarely intentional, but is rather the result of ignorance; yet the consequences to the patient are none the less disastrous. It must be conceded that local treatment in these cases, except for occasional short periods when especially indicated by varying conditions, is often useless. Far more important is the removal of all causes which may be still operative to produce further impairment of hearing acuity. Such causes may be found in disturbances of function of the upper respiratory tract or in focal infections, even as remote as in the intestinal tract. For the patient's best interest it is of the greatest importance that everything be done to preserve as long as possible what remnant of hearing he has left, for even a slight remnant is useful in keeping up communication with the outer world. Since many cases of impaired hearing in adult life are the result of pathological conditions in remote parts of the body, the skill of the internist or the surgeon may be required. Often noticeable improvement in acuity of hearing follows the application of measures to improve the general health.

Our most helpful resource in solving the problems of those who are already materially deafened is found in lip reading. Too much cannot be said in favor of this boon to the hard of hearing. As the blind substitute hearing and the sense of touch for sight, so, even with a greater degree of success, the deafened, with a mind trained to alertness and application, can substitute the sight for hearing. The accomplishments of the skilled lip reader

in the understanding of spoken language are truly marvelous. It is very important that all those whose impairment of hearing requires any considerable effort to understand the conversational voice should be urged to begin lip reading at once in order to compensate for the diminishing acuity.

While lip reading can not be acquired with equal proficiency by all, nor does it prove always infallible, and can not be depended upon in all business relations, it does more than any other measure to mitigate the sense of isolation of the deafened and improve his outlook upon life. Every one with good vision can become more or less proficient in the art, good results being obtained by many in three or four months of close application. Others require more time. The highest degree of skill can only be attained by years of training.

Many in the group of hard of hearing, but by no means all deafened persons, derive much help from the use of one or another of the various electrical devices for the hard of hearing. Through the application of some of the newer principles of amplification employed in the radio-phone this form of apparatus promises an increasingly wider range of application among the deafened. All apparatus of this sort should be purchased only after trial.

Education and Vocational Training.—The physician's responsibility to the deafened does not end with giving him the best medical care and advice, referring him to a teacher of lip reading and possibly suggesting that he try an electric ear phone. Because of his better understanding of the deafened patient's peculiar needs, from infancy to old age, the physician is to be regarded as the special friend and adviser of the hard of hearing in regard to his educational and vocational requirements. He should, therefore, keep himself informed as to the various agencies provided to meet the needs of this group.

In the majority of our states generous provision is made for the education and vocational training of the hard of hearing of school age. Minnesota ranks well in this regard and we have in our state a school for the deaf, with its 270 pupils, an excellent institution, which has done wonderful service under the fine leadership of the late Dr. Tate.

All teachers of the deaf emphasize the great importance of beginning the specialized training of the young child at the earliest possible age. The

ideal condition would make the mother the special teacher, and this can be accomplished in a measure if the mother is intelligent and is informed of her great responsibility, and can be given the right supervision. The family physician can be of the greatest help in putting her in touch with the proper agencies and literature to direct her in the care of her deafened child.

Children under 8 years of age, unfortunately, are not admitted to our state school for the deaf. In consequence, several of the most valuable years for the acquisition of knowledge and flexibility of speech are lost.

Recently enacted laws make it now possible for any school district, in which there are a minimum of five hard of hearing pupils between the ages of 4 and 21 years, to organize a day school for the deaf, employing a specially trained teacher. For each child state aid in the sum of \$250.00 is granted, and a further sum of \$100.00 may be allowed for transportation. Thus, the benefits of special instruction may be extended to the residents of smaller communities in their own homes, beginning at the age of 4 years, when the greatest amount of good can be done them. Day schools for the deaf in Minnesota already exist in Minneapolis, St. Paul, Duluth and Rochester, and will doubtless soon be formed in other places, as the possibilities of the work become better known.

Social and Economic Problems.—The social and economic problems of the hard of hearing are very important and real to the afflicted. They grow out of the peculiar psychology of this class and can be best met by those who understand the viewpoint of the deafened. Here again the physician, or one who has made a special study of their needs, is best able to alleviate the condition of this large group. This includes the many who have become deafened during adult life. This class calls for special consideration, for their distress is often very acute. Unaided, the recently deafened man faces a calamity of large proportions. In the words of Dr. Wendell C. Phillips, "to him must be imparted courage and inspiration to enable him to throw off the depression, dependence, diffidence, lack of self-reliance and self-pity, which are the outgrowth of his condition. He must be shown how he can overcome his defect by substitution, how he can make the very most of what he has left, how he can adapt himself by rehabilitation

to a new life made not only tolerable but happy through occupation and usefulness."

These problems of the deafened in many larger communities are being best met by special organizations composed largely of the hard of hearing, whose object it is to do social service work among their own kind. During the past few years many such organizations have been formed. They have recently united in the American Federation of Organizations for the Hard of Hearing. The features of such local organizations embrace some of the facilities of a club, furnishing primarily a home for their chief activities. An ideal organization of this kind consists of three types of individuals, the otologist and physician, the social worker and those with acquired deafness. "These all unite in a combined effort to arouse the deafened man or woman out of despair and make them over into alert, happy, hopeful and self-supporting citizens." —Phillips.

Their activities include classes in lip reading, the maintenance of an employment bureau, various social and study clubs to entertain their members and to give them opportunity for self-expression.

The employment bureau is a thoroughly appreciated feature, bringing together those capable of rendering superior service and employers who are in real need of the dependable help which the deafened man or woman can render, often more efficiently than those with normal hearing. It is surprising how many fields of work are suited to the capabilities of the individual who is hard of hearing, especially if he is trained or experienced and has learned lip reading. In the work of the employment bureau for the deafened, it is only a question of fitting the right person into the right place.

Further activities of these local organizations include social clubs, lecture courses, radio clubs, entertainments and other opportunities for culture and the formation of helpful, sympathetic friendships—all calculated to meet the higher needs of the individual. Attempt is also made to do as much welfare work as possible among those similarly afflicted, including an intelligent propaganda for the prevention of deafness. No class is more keenly interested in this phase of the work than the deafened themselves, who are most eager that others be spared the same affliction as their own. Again quoting Dr. Wendell C. Phillips, "All these activities react most favorably upon the individual

and transform him into a helpful, self-respecting, inspiring member of his community."

In our larger cities with large membership, including often persons of means and leisure, a more pretentious program is consistently followed. In Chicago a careful survey of the condition of children in a typical public school, as regards the hearing, was undertaken under the auspices of the local league for the hard of hearing. This has yielded valuable information. In another city a free ear clinic in the public schools was established. In some communities a committee on legislation regarding the deafened is maintained.

Already twenty-four such organizations have been formed in the United States. Of these Minnesota boasts one, the Minneapolis League for the Hard of Hearing. Although less than two years old, it has a membership of 150, maintains an attractive club room with a good library, carries on numerous helpful activities and, under the guidance of an executive secretary and generously supported by an enthusiastic group of helpful citizens, is already serving a useful mission.

The national organization, the American Federation of Organizations for the Hard of Hearing, which holds its fourth annual meeting in Washington, D. C., in June, 1924, is at all times ready to help in any legitimate way the individual deafened person, the parents of deafened children, the physician or any one interested in the welfare of the hard of hearing. It generously assists groups to form local organizations, acting most efficiently in an advisory capacity in this work. It has adopted as its official organ the *Volta Review*, which enjoys a wide circulation among the deafened and those interested in the problems of the deafened.

From the point of view of the otologist and physician, the formation of local organizations with the purposes outlined is desirable in all communities of sufficient size to justify the undertaking. Such an organization takes up the work for those with impaired hearing where the purely technical work of the otologist and the physician ends. His recognition of the service of such organizations is best shown by his personal participation in these activities and by acquainting his hard of hearing patients with the advantages of affiliation with a co-operative association of this kind. By lending his personal encouragement and active support he will aid in solving many of the problems of the hard of hearing more effectively than by working alone.

DISCUSSION

DR. CARL L. LARSEN, St. Paul: Dr. Newhart has brought to your attention a very important and a much neglected subject. The larger cities have for many years given this subject considerable thought and attention but unfortunately the smaller cities and particularly the rural communities have shamefully neglected this form of modern day education.

Chicago with seventeen thousand totally deaf people and twice that many partially deaf, is doing a wonderful work not only in private but in public schools.

Dr. Meyerding, who is very much interested and who has charge of this form of education in St. Paul, informs me that he has three teachers devoting their time to lip reading or oral education. There are at present twenty-two students, fourteen of whom are totally deaf and eight partially so.

If the medical profession and the public were aware of the splendid opportunities afforded these unfortunate people, thousands would be saved from a life of uselessness and misery and made happy, useful and helpful citizens.

DR. THOS B. HARTZELL, Minneapolis: This morning I spent an hour reading the conclusions of a committee which had investigated the feeling of the laity among seven thousand people toward the medical profession. In that seven thousand eight hundred I believe there were nearly seven thousand who said untrue, critical and unkind things about the medical profession; and the conclusions reached by the persons who gathered this information was that the medical profession does not instruct the laity as much as they should, that the wrong system of ethics which is maintained by the medical profession precludes the physician's telling those who most need him what he can do for them. If there is any one thing in the gospel of healing that is overlooked, it is this matter of deafness. The number of people who are suffering from loss of hearing who should be benefited is very great; and only just now and then do we find anyone who knows anything about facilities for correcting the difficulty.

It does seem to me, as a member of the medical profession, yet still standing on the sidelines, that we owe it to ourselves and to each other to take some more comprehensive method of bringing to the knowledge of the people the real truth about the things that can be done for the individual and are not being done because of the extreme delicacy that the medical man who is honest and upright and clean thinking conceals his light under a bushel.

I know in my own experience through the partial loss of hearing on one side and regaining it by a definite operative interference, how great the comfort has been. I feel rather deeply on this subject, and that is why I am taking your time to applaud this paper and to commend to you the thought that we are not doing enough to protect our national honor in teaching what we well might teach to the public who greatly needs it.

DR. HORACE NEWHART, Minneapolis (closing): Since there are other papers, and the hour is already late, I will not take any more time, except to thank those who have so generously discussed my paper.

THE THERAPEUTIC USE OF GERMANIUM DIOXID IN SECONDARY ANEMIA*

JOHN D. GARVIN, M.D.

Fellow in Medicine

The Mayo Foundation, Rochester, Minn.

TECHNIC

In the early part of our work a 0.2 per cent acid aqueous solution was given orally and hypodermically. Later the 0.4 per cent alkaline solution was used, thus securing the anion form of the germanium, which was thought to be more effective.² In preparation of this, 500 mg. of the element was dissolved in 125 c.c. of sterile, distilled water, in a sterile flask, and N/10 sodium hydroxid was added to aid in dissolving. This was then titrated back with N/10 hydrochloric acid to a hydrogen ion concentration of 7.6. From 3 to 5 c.c. of this solution, containing from 12 to 20 mg. of the germanium, was given hypodermically every one to three days. When the solution was given by mouth, from 10 to 200 mg. was given at a dose. With the exception of three cases mentioned later, the blood counts were "checked" at least twice. The hemoglobin determinations were made by the Dare and Palmer-Haldane methods, the standard of the latter being verified at frequent intervals by the oxygen capacity method of Van Slyke. Owing to the inadvisability of performing venipuncture unnecessarily, the Palmer-Haldane hemoglobin readings were dispensed with as often as was practicable.

RESULTS

Of the nineteen cases observed, a marked effect following the administration of germanium dioxid was noted in only two—one case of chronic nephritis (Case A401495), and one of chronic infectious arthritis (Case A400821). In both of these there was a rise of from 800,000 to 900,000 erythrocytes in the first twenty-four hours. These results we are unable to explain, as such a rise was not encountered later in similar cases, even with much larger doses. In these cases, the first to be observed, the erythrocyte counts were not made in duplicate as in the later cases. Case A422438, that of a woman with a bleeding duodenal ulcer and possible chlorosis, shows the most, and practically only, rise in hemoglobin. This we cannot ascribe to the germanium alone, as the patient had 45 grains of Bland's pills a day for three weeks. Furthermore, there were no symptoms of hemorrhage from the ulcer during her stay in the hospital, although she had noticed blood in the stools several times shortly before her admission. The ulcer was later cauterized, and gastro-enterostomy performed.

Germanium dioxid as a therapeutic agent was first brought before the medical profession by Hammett, Nowrey and Müller through their work at the Wistar Institute.^{**} Their investigations on albino rats revealed a marked rise in the number of erythrocytes following the administration of the germanium. It was also shown that "in the bone-marrow of rats which had received the germanium there was evidence of marked stimulation in formation of nucleated erythrocytes, in that many more of these cells were found here than in the marrow sections of the controls." On this basis they maintained that "the source of the erythrocythemia produced was the increased production of red cell precursors by the bone-marrow stimulated to increased activity."⁴ They showed that relatively large doses, 586 mg. for each kilogram of body weight, cause toxic symptoms, from overstimulation of the blood-forming organs, and that the drug does not accumulate, but is eliminated rapidly through the kidneys and alimentary tract.

Müller and Iszard believe that germanium dioxid has a decided erythropoietic effect in the guinea pig, rabbit, dog, and man, one case being reported in which the erythrocyte count was normal.

Kast, Croll and Schmitz reported sixteen cases, in some of which the germanium was found to have a distinct erythropoietic action. They also reported that there was no effect on the kidneys, as determined by urinalysis and blood chemistry. Other writers have held that, in the treatment of secondary anemias, "germanium dioxid certainly cannot be displaced."⁶

Our investigation was begun in August, 1922, and has proceeded continually since that time. Nineteen patients have been treated for varying periods of time, most of them for the anemia of chronic nephritis, or of chronic infectious arthritis. A few cases were studied in which the anemia was very mild.

*From the Division of Medicine, Mayo Clinic.

**For our supply of germanium dioxid and for splendid co-operation in our investigation, we are greatly indebted to Dr. Hammett and his associates.

If, as it has been shown by Hammett, Nowrey and Müller, the erythropoietic action of germanium is due to the stimulating effect on the bone-marrow, it is really not surprising that no marked results were obtained in the cases of chronic nephritis. For, as shown by Brown and Roth, the anemia in such a condition is owing not only to involvement of the kidneys, but to actual disease of the bone-marrow itself, involving the function of hemapoiesis. The possibility that slight, if any, improvement can be expected in cases in which the bone-marrow is diseased, was also recognized by Hammett.

CONCLUSION

Germanium dioxid in either acid or alkaline solution, in cation or anion form, given hypodermically in doses of from 12 to 20 mg., or by mouth in doses of from 10 to 100 mg., every one to four days, over periods ranging from one to five weeks, produced practically no increase in the number of erythrocytes, nor any appreciable rise in the hemoglobin content of the blood, in our series of nineteen cases of anemia associated with chronic infectious arthritis, chronic glomerulonephritis, and chronic sepsis (Tables 1 to 11).

THE RESISTANCE OF MALARIA TO QUININ

In 1917, reports began to appear that English soldiers in the tropics were being attacked by malaria that quinin would not cure. A report was published that quinin was ineffective in cases that were complicated by dysentery. An extensive study has demonstrated that quinin will cure malaria and that dysentery does not prevent the cure. In these cases the physician administered the quinin by mouth

and made sure that it was swallowed. A study of the intramuscular injection of quinin demonstrated that necrosis of the muscle always occurred and that the absorption was less satisfactory than when the drug is given by mouth. It was shown that there was a profound fall in blood pressure when quinin is introduced intravenously, and one case of death and one case of serious sepsis are reported. It was also found that quinin is too irritating to be administered by rectum.—(*Journal A. M. A., April 5, 1924, p. 1125.*)

POSTOPERATIVE MASSIVE COLLAPSE OF THE LUNGS*

F. J. HIRSCHBOECK, M.D.

The Duluth Clinic
Duluth, Minn.

In a previous article¹ I called attention to the relative frequency of postoperative massive collapse of the lungs as a postoperative pulmonary complication, summarizing the literature and adding my own experience, in an effort to call attention to its clinical entity and distinctive symptomatology. Shortly before this, Scrimger² reported several cases, incorporating roentgenograms, which revealed strikingly the alteration in the relationship of the thoracic viscera. Unfortunately, roentgenographic studies were not made on my reported cases, but the opportunity of witnessing the clinical course of another case recently, with the associated roentgenologic data, prompted me to present the subject before you.

Historical.—W. Pasteur³ first called attention to the occurrence of massive collapse of the lungs in 1890, basing his report on an experience with post-diphtheritic paralysis of the diaphragm and other accessory respiratory muscles. This was further elaborated in two subsequent presentations^{4,5}, in which he described the macroscopic pathology, and drew attention to its occurrence postoperatively as well as post-diphtheritically, and advanced the theory of the active contraction of the part affected as the most reasonable cause.

The condition was subsequently described by Dingley and Elliot⁶, Rose-Bradford⁷, Briscoe⁸, Scrimger², and Elwyn and Girsdansky⁹.

Pathogenesis.—Through clinical and experimental investigation it has been thought that massive collapse of the lungs is due to one of two causes or both: (1) Obstruction of the bronchial tubes; (2) Immobility of the diaphragm or accessory respiratory muscles.

In 1878, Lichtheim¹⁰ produced a condition in rabbits similar to massive collapse, introducing laminaria plugs in a bronchial tube, resulting in a collapse of the lung portion tributary to the bronchus subjected to the experiment. The examination of the viscera showed the alveoli virtually closed by absorption of the air content, producing a negative

pressure and causing thereby a dislocation of the neighboring organs toward the affected area.

Its occurrence as a result of post-diphtheritic phrenic paralysis suggested to Pasteur the influence of immobility of the diaphragm and accessory respiratory muscles as a cause. He believed that the process of deflation was not due to alveolar absorption of air, but rather to the unopposed contraction of the pulmonary tissue no longer prevented by the muscular excursion of the chest on account of immobility of the chest wall.

Rose-Bradford also pointed out that the condition occurred most commonly in patients who had injuries necessitating immobilization for a period of time, such as gunshot wounds in the chest, abdomen or legs. It rarely if ever occurs in injuries about the head or arms, because of the patient's ability to be up and about. Postoperative cases requiring absolute bed rest are a fertile field for the production of this condition, as it is never found in ambulant cases, and the immobilization of the body, with the resultant immobility of the thoracic musculature, is the most potent cause.

Scrimger believed that the lesion was due to an abdominal interference with the vagus control, causing a contraction of the muscular elements of the lungs, aided by a subsequent collection of mucus in the bronchial tubes, sufficient to prevent the ingress of air, and leading to an absorption of the alveolar air contents, and eventually to collapse. This is in accord with my belief, as pointed out in my previous publication, since clinically there is sufficient proof that immobilization is a profound factor, whereas experimentally the same condition has been produced by plugging of the bronchial tube, even though the latter is not or only rarely found at post-mortem examination. As a result of abdominal trauma in laparotomy the resultant recumbent position exerts an influence in bringing about collapse of the lung, by a fixation of the diaphragm, on account of reflex inhibition and an effort on the part of Nature to splint the traumatized vicinity. The admonition to operative patients to take deep breathing exercises systematically after operation not only tends to promote aeration of the distal parts of the bronchial tree, but tends to reduce the immobility of the perithoracic musculature. In the patients seen by me it has not occurred in individuals who were exhorted to indulge in this practice. Coincident with the fixation of the diaphragm and chest muscles, mucus forms

*Read before the annual meeting of the Minnesota State Medical Association, St. Paul, October, 1923.

in the bronchial tubes, and is not expelled, causing an obstacle to the ingress of air in the smaller bronchial tubes, leading ultimately to alveolar absorption of the air into the circulation or gradual expulsion by pulmonary contraction.

Occurrence.—As pointed out by Pasteur, massive collapse occurs more frequently than embolism, abscess or pleural effusion (either of the serous or purulent type), but is not as frequent as pneumonia, bronchitis or dry pleurisy. It was observed by him in twelve of 201 lung complications following 3,559 operations in the Middlesex Hospital between 1903 and 1910. He later observed sixteen cases in 1,930 laparotomies in the years 1911 and 1912.

The condition is by no means infrequent. Rose-Bradford has pointed out that it occurs in 5 to 10 per cent of all chest injuries incurred in military practice.

It has been noted in massive collapse that the extent and site of involvement vary considerably. In some instances there is only a partial involvement of one of the lower lobes of the lungs; in others, the condition is more extensive, involving a whole lobe, or even an entire side. It is frequently bilateral, and, if so, affects particularly the lower lobes only. Rose-Bradford has pointed out in his consideration of the subject that unilateral trauma causes collapse not only on the affected side but frequently on the contra-lateral side as well.

Physical Signs and Symptoms.—The physical signs and symptoms of massive collapse are so distinctive as to establish the condition at once as a definite clinical entity. The exciting factor in civil practice is usually trauma, accidentally incurred or otherwise, necessitating immobilization of the body, but it undoubtedly follows post-diphtheritic paralysis of the phrenic nerve not infrequently, as pointed out by previous observers. It has been known to follow all methods of anesthesia. Rose-Bradford has pointed out its common development in military practice in gunshot wounds of the chest, abdomen and lower extremities, but in civil life abdominal operations are the most frequent cause of the condition, on account of the immediate effect in producing relative immobility of the diaphragm and deficient aeration of the lungs.

The symptoms may develop within a few hours or as late as one week after the exciting trauma, but it usually develops in two or three days. It is characterized by sudden onset, a rapid course over a period of from two to five days, and resolution

which is usually, clinically, rather prompt, but pathologically and roentgenologically slow. The degree of fever is usually moderate, and not in proportion to the marked increase in the pulse rate or the respiration rate. The fever may be as high as 103 or 104 degrees, the coincidence of the inflammatory phenomenon probably influencing the height of the curve. The temperature in the cases observed by me was usually between 102 and 103. The respiration rate is undoubtedly increased by the immobility of the affected part, by accompanying pleuritis or by toxic conditions incident to an inflammatory superimposition. The pulse rate peculiarly is out of proportion to the respiratory and thermic curves, and has a tendency, with the respiratory rate, to remain relatively high even after the temperature is normal.

The physical signs are striking and characteristic. On inspecting the chest one is impressed by the diminished or absent excursion of the chest wall over the affected area. The cardiac impulse is displaced toward the affected side, and is as marked on the left-sided cases as in those occurring on the right side, the apex tilting upward and outward so that it not infrequently is felt in the axilla. In right-sided affections the impulse may be felt at the tip of the sternum or to the right of it, and by the unwary has been interpreted as a dextrocardia. Roentgenographic studies corroborate the signs elicited by inspection, and reveal the most marked retraction of the heart toward the affected area, unusual ascension of the dome of the diaphragm, and partial or total collapse of the pulmonary area. In bilateral affections the displacement of the heart is not noted, but the high position of the diaphragm and the collapse of the lungs is easily demonstrated. On palpation the intercostal spaces on the affected side are found to be narrowed, leading to a relative approximation of the ribs. The percussion note over the affected area is dull, and may approach flatness, but it is to be pointed out that in left-sided cases the lower part of the chest wall is highly resonant, due to the abnormally high level of the diaphragm, the liver interfering with this symptom on the right. On the contralateral side hyper-resonance is noted. The breath sounds and fremitus are usually increased to an enormous degree, but may be diminished or absent, according to the observation of others. The transmission of voice sounds may be so intense as to approach whispered pectoriloquy.

In the five cases observed by me, bronchophony was present in five cases, and diminution in the breath sounds or fremitus was noted in no case. The alteration in the transmission of sounds is due to relative proximity of the affected area to patent bronchial tubules.

Râles are usually absent in the early stage, but with the development of a bronchitis, pneumonia, or when resolution takes place, they become more marked, particularly in the latter stage, when the expectoration is more profuse. With resolution the heart gradually returns to its normal position, the lungs slowly expand, and the diaphragmatic dome flattens out, but this usually is a slow restoration, requiring on the average about fourteen to twenty-one days for its completion.

The extent of the symptoms depends upon the amount of lung tissue involved, and whether the condition is unilateral or bilateral. Dyspnea may be moderate or extreme, the latter being common in bilateral cases. The general impression on observing the patients is that they are not suffering from extreme discomfort. Cough is slight, as a rule, in the beginning, with scanty expectoration, but in the later stages it is accompanied by a profuse, mucopurulent sputum. The sputum is rarely, if ever, bloody—an important consideration in the differentiation between pneumonia or infarct and collapse. The conditions which must be carefully differentiated therefrom are: bronchitis, pleurisy, pneumonia, effusion, subdiaphragmatic abscess and pneumothorax.

The symptoms, however, of collapse of the lungs, are so definite that differentiation from the other conditions is easy. The development soon after operation, the absence of a bloody sputum in spite of the evident pulmonary complication, the extreme dullness and increase in breath sounds with scant expectoration, the exaggerated displacement of the heart and diaphragm, and the rapid relief from subjective symptoms in the course of two to five days, aid in the differentiation from the conditions mentioned, and the condition has but to be kept in mind to render its recognition easy.

It is not uncommon for evidences of bronchitis to develop during the period of resolution, which tends to make the condition more protracted as far as active symptoms are concerned, and pneumonia may develop in the affected area.

In view of the fact that the roentgenologic evidence is so confirmatory, and because it is so char-

acteristic of this condition, I am submitting a case report of a patient recently observed by me through the courtesy of Drs. W. R. Bagley and P. S. Rudie of Duluth.

Mrs. K. O., admitted to St. Mary's Hospital, Duluth, June 20, 1923, under the care of Dr. Bagley, who made a diagnosis of purulent salpingitis of the right Fallopian tube, and chronic salpingitis on the left side with a cystic ovary.

An operation was performed under ether anesthesia on June 21, 1923, with a low abdominal midline incision. The uterus was found in good position. The left ovary was cystic and partially removed, as well as the left tube, and the right tube and ovary were removed in their entirety.

Fig. 1. Roentgenogram of massive collapse of the lung taken the third day of illness, June 24, 1923.

The operation was uneventful and uncomplicated but for the use of a drainage tube as a safeguard. On removal it was found that the right tube was dilated and filled with a thick yellow pus. The mucosa was considerably congested and the wall thickened. The left tube on the cut surface also showed thickening of the mucous folds and a small amount of pus in the lumen.

On June 22nd (the day after the operation), the patient's temperature was elevated to 102.6 in the afternoon, after a slight rise, in the morning, to 100.6. The pulse rate was 130 to 140 early in the morning, and remained at that high point all day. The respiration rate was between 28 and 38. With slight remissions this continued for three days, until the 25th of June, when the temperature had receded to 100 degrees. The pulse rate was 110, and the respiration rate 28.

On the 26th there was a slight increase in the temperature, the pulse and respiration rate, but only of a transitory character. From this time on the patient made a

rapid and uneventful convalescence from the clinical standpoint.

The day after the initial onset (on the 23rd of June) there was noted an entire absence of right chest expansion, with dullness over the whole right lung. It was noted that the apex beat was just to the right of the sternum.

On the 24th, tubular breathing was noted throughout the right lung, and a roentgenogram showed the heart displaced almost entirely to the right side, with the margin of the heart on the left side just barely demonstrable to the left of the sternum. The dome of the diaphragm was not visible on account of the blending of the liver and consolidated lung shadows. The left chest was hyper-resonant throughout. There was no dullness to percussion over the normal heart area, the usual dullness being replaced by pulmonary resonance. The patient was coughing but slightly, and had moderate dyspnea, relieved by a reclining position in bed. At no time was blood observed in the sputum.

With the disappearance of the fever the patient's clinical symptoms improved subjectively, but repeated examinations daily showed only a very gradual improvement in the physical signs. On the 2nd of July the expansion on the right side was still diminished, but not as marked as before. On percussion the left lung was apparently normal; on the right side there was impaired resonance from the base to the level of the fourth dorsal spine. Anteriorly the impairment of resonance was slight. Tactile fremitus was increased in the right base, and some râles were audible in the affected area. The heart sounds were apparently normal, but the displacement was still extreme.

Fig. 2. Roentgenogram taken on July 20, 1923, after resolution was complete.

On July 2nd, the roentgenogram was virtually unchanged as to findings.

On the 20th of July the last roentgenogram was taken.

The lungs were found to be clear at that time, and the heart had returned to its normal position.

DISCUSSION

DR. GEORGE D. HEAD: Mr. Chairman and gentlemen: I have made a diagnosis of massive collapse of the lung in one case, but that case unfortunately did not come to a post-mortem so that I am not sure that my diagnosis was correct. I think the article by Rose-Bradford in the *Quarterly Journal of Medicine* is very illuminating to every man who wants to post himself on this rather rare condition. It is quite possible that it is not as rare as we think and I presume a good many cases we have diagnosed as post-operative pneumonia, or at least some of them, may have been due to this condition.

I must confess that, looking at it from the standpoint of the practical clinician, the diagnosis which would come immediately to mind, where one was called upon to differentiate between this condition of massive collapse of the lung and some other post-operative intrapulmonary complicating condition, would be either a pneumonia, lobar or bronchial, or an infarct of the lung. Occasionally, of course, possibly following some operative procedure like a tonsillotomy, one might think of abscess of the lung and possibly occasionally, if it should occur in some chronic ailment, gangrene of the lung. But from the standpoint of the practical clinician it would strike me that we ought to center our attention upon the differentiation between pneumonia and massive collapse of the lung.

Fortunately for us in attempting to make that differentiation Dr. Hirschboeck has suggested that mastery inactivity is good treatment in massive collapse of the lung and there is nothing to be done but to leave the patient alone; therefore, if we do not use meddling interference, our patient will probably get well. The patient that I saw had a bilateral condition with profound cyanosis, unconsciousness, absolute loss of all respiratory sounds upon both sides of the lung, without displacement of the heart. There were no roentgenological studies made. The patient died in this condition within twenty-four hours. There was absolutely not a breath sound to be heard upon either side of the chest, and the patient was in an extreme dyspnea with cyanosis.

Where it occurs unilaterally, judging from Dr. Hirschboeck's writings and from the Bradford reports, I would say that the condition which one might confuse it with

most likely would be pneumothorax because your attention would be particularly attracted to this tremendous dislocation of the heart, and then the fixed high line position of the diaphragm would be likely to attract a man's attention as soon as he fluoroscoped the chest or had a chance to get an x-ray picture of the chest.

The pictures which Dr. Hirschboeck has shown are certainly extremely interesting and instructive. I must say that we need information and I am glad that the doctor has brought this subject before us. I would like to ask him whether or not in the cases that he has seen the leukocyte count has been of any value in differentiating between pneumonia and this condition, whether or not the differential leukocyte count has been of any value in the differentiation. As I said before, we need all the help we can get in attempting to differentiate this condition. It would strike me that from an etiological point of view we could consider it something of the same nature as the condition which we find in acute nerve paralysis such as one sees in acute gastric dilatation or in acute post-operative ileus. It must be something of that sort. It is not reasonable to think that it could be due to anything mechanical; at least the patient I saw did not give any indication of a plug in the bronchus or the branch of the bronchus.

DR. EDWARD L. TUOHY: Dr. Hirschboeck has given you about all I know concerning this clinical entity but I would like to hammer in a few points: Post-operative cases are assumed to have some inflammatory lung complications, without going over them very carefully, because it is impossible to examine people who are in distress and uncomfortable, and it is only recently that roentgen plates have come into use, to uncover these changes which can occur in the lung and not be noticed clinically. In the next place, the cases that are unilateral usually recover. We were fortunate in having an early bilateral instance which came to us, and it drew our attention very forcefully to massive collapse.

I referred this morning to having met Sir John Rose-Bradford. I discussed massive lung collapse with him per-

sonally, and he said that he had discovered four reports in the British literature in which the men discussed "Odd types of pneumonia in which the heart was pushed towards the affected side." He said, "Obviously these were not pneumonias at all but were instances of massive collapse."

In the next place, men doing post-mortems and finding considerable areas of the lung collapsed have not paid any particular attention to the etiological factors found, but have reported them as "collapse or atelectasis." Someone, I think it was Willard Bartlett, of St. Louis, made the recommendation that all post-operative cases should be urged, immediately after they come out of the anesthetic sufficiently to understand, to take long deep breaths. This I consider a very valuable safeguard against lung complications and every post-operative patient should be given that advice. In the next place the makers of adhesive plaster should not be given too much of an advantage by plastering the patient all the way from the pubis to the larynx. Give the diaphragm a chance.

DR. F. J. HIRSCHBOECK (closing): I do not believe the condition is by any means rare. It has been described a good many times in England as they are apparently on the lookout for it. From the case reports it is not uncommon. Pasteur pointed out that it was more common than abscess, embolism or pleurisy. It is nearly as common as pneumonia, but not as frequent as bronchitis. Differential diagnosis should not be difficult because the findings are pathognomonic. The displacement of the heart is an important sign. If it is on the left side it is sometimes very difficult to diagnose, because the diaphragm is extremely high. We find a good deal of resonance on the left side while the right side is not so resonant.

I am glad that Dr. Tuohy mentioned deep breathing. We usually have the patients take eight or ten deep breaths every morning and evening and they very rarely have pulmonary complications, in fact, they rarely contract pneumonia. We have made leukocyte counts and found a range from 11,000 to 26,000. Differential counts were not made.

ANTI-PNEUMOCOCCIC SERUM TYPES I, II AND III AND POLYVALENT

The New and Non-official Remedies' description of anti-pneumococcus serum stated that thus far only the Type I serum seemed to be on reasonably secure clinical ground. In consideration of favorable reports on the use of anti-pneumococcic serum which, in addition to the Type I organism, also represented Types II and III and Group IV, the Council on Pharmacy and Chemistry accepted such "polyvalent" serums. At its 1921 annual meeting, the Council considered the available evidence for the use of anti-pneumococcus serum. The conclusion was reached that there was a preponderance of evidence against the employment of a serum which represented organisms other than Type I. Accordingly, the Council has omitted from New and Non-official Remedies all anti-pneumococcic serums which represented organisms other than Type I.—(*Journal A. M. A., April 5, 1924, p. 1138.*)

PARATHYROID GLAND THERAPY

The administration of parathyroid gland has been reported of value in the treatment of a number of cases of tetany following the operative removal, or the injury of the parathyroid gland. It has prevented the attacks of tetany and of infantile tetany and seemed at times to have prolonged life, or to have saved it, while the injured glands regained their functions. It has been stated to be of value in some cases of gastric tetany, although in other cases the results were negative. Parathyroid gland has been used by some one or another at some time (and claimed to be of value) for conditions such as varicose ulcers, gastric, duodenal and cervical ulcers, tuberculosis, sinus of the hip, paralysis agitans, eclampsia, etc., but that such disorders are regularly and favorably affected by parathyroid gland administration is a conclusion unsupported by controlled clinical evidence.—(*Journal A. M. A., April 19, 1924, p. 1286.*)

CHRONIC NEPHROSIS* **

LEO G. RIGLER, M.D., and HAROLD RYPINS, M.D.
Minneapolis

The confusion in the terminology of renal diseases necessitates, at the very outset, an accurate definition. Nephrosis, according to Bell,¹ is a degenerative non-inflammatory process, largely confined to the tubular portion of the kidney. Space does not permit a consideration of the origin of the term "nephrosis," first applied by Müller,² nor of the extensive and rather polemic literature which has grown up about it. The acute nephroses are well recognized clinically and are one of the commonest forms of renal disease found at autopsy. They are present quite constantly, to a more or less degree, during the course of practically all the acute infections and toxemias, but are most typically seen following poisoning by the mercuric salts, chromates and tartrates. Chronic nephrosis, as either a clinical or pathological entity, is less clearly recognized. Although Volhard and Fahr³ reported thirty-three cases, Bell¹ in his extensive series has never found one clearly recognizable case. Many of Volhard and Fahr's cases were undoubtedly amyloid disease of the kidney and there is considerable doubt as to the authenticity of the remainder of their cases. Nevertheless, Von Monakow,⁴ Munk⁵ and others have reported similar pathological studies.

In this country, interest in chronic nephrosis, as a clinical entity at least, has centered largely in the contributions of Epstein⁶ of New York. On the basis of clinical, chemical, and metabolic studies, he has arrived at an original and somewhat startling conception of the disease. Chronic nephrosis, according to Epstein, unlike chronic glomerulo-nephritis, is not primarily or essentially a disease of the kidney. On the contrary chronic nephrosis is an organic, metabolic disturbance of which the massive albuminuria and edema are secondary symptoms. A review of the evidence by this author⁷ covers the subject completely.

Essentially, he describes the condition as a metabolic disturbance, the etiology of which is not definitely known, and which may be associated with hypothyroidism. The massive albuminuria is the

result of this metabolic disturbance and the loss of albumin produces a reduction of serum protein, particularly of serum albumin, with a relative increase of serum globulin. Normally the blood contains from 4 to 6 per cent serum albumin, 2 to 3 per cent serum globulin, and 6 to 8 per cent total protein. In this disease the total protein may be reduced to as low as 3 per cent, the serum albumin to as low as 1 per cent, the serum globulin remaining the same. Utilizing Starling's theory, that the osmotic pressure of the colloids of the blood tends to prevent exudation of fluid from the capillaries, it can be seen that this change in the serum protein might easily cause edema. Confirmation of this theory has recently been afforded by Kisch,⁸ and Kollert and Starlinger.⁹ Epstein also found quite constantly a marked increase in the lipid content of the blood, the cholesterol increasing from the normal of .175 to .225 per cent up to as high as 1.3 per cent. As a further contribution to the metabolic nature of the disease, Epstein and Lande¹⁰ have recorded the basal metabolic rates in a number of these cases and conclude that it is reduced. Their results, however, are not convincing. With these facts and theories in mind, Epstein has proposed that these patients be put on a high protein, fat poor diet, together with thyroid extract, and has reported a considerable success with this form of treatment. The diet consists of protein, 120 to 240 grams; fat, 20 to 40 grams; carbohydrate, 250 to 300 grams; the total calories for twenty-four hours being 1,280 to 2,500. The purpose of this diet is to replace the serum albumin which is lost through the kidneys, to reduce cholesterinemia, and to raise the metabolic rate.

That Epstein's views are not well established can easily be seen from the conflicting views in the literature which he reviews.⁷ Kahn¹¹ failed to find the changes in the serum protein which Epstein described. Geyelin,¹² Christian¹³ and others do not recognize the existence of the disease as a separate clinical entity, nor do they admit the efficacy of the treatment. On the other hand, Schwartz and Kohn¹⁴ have recently reported a group of similar cases occurring in children, in some of which the treatment was used with apparently good results. Another recent case report is that of Baker.¹⁵ Eppinger's contribution¹⁶ as to the results of thyroid therapy is of great value. In spite of these conflicting reports there is no doubt that

*Presented before the annual meeting of the Minnesota State Medical Association, St. Paul, October, 1923.

**From the University Medical Division of the Minneapolis General Hospital.

Epstein has described a clinical picture which is different from the ordinary case of chronic glomerulo-nephritis. Inasmuch as the treatment is also radically different from that ordinarily used in the latter disease, it is of some importance to attempt to differentiate the two diseases.

The salient characteristics of chronic nephrosis can be summarized briefly as follows. It is a general metabolic disease, of doubtful etiology, gradual onset and protracted course. The pathology consists chiefly of a degeneration of the tubular portion of the kidney with little or no effect upon the vascular system. Clinically, the disease is characterized by massive edema, anasarca, anorexia, and general weakness. The urine is of a high specific gravity, small in quantity, contains very large amounts of albumin, casts, and rarely red blood cells. The blood shows little or no anemia, lack of any marked nitrogen retention, but a decrease in the total protein and a reversal of the normal albumin-globulin ratio. The cholesterol of the blood is usually increased and the basal metabolism is often subnormal. The prognosis has not yet been established and the treatment consists of a high protein, fat poor diet together with thyroid extract.

Inasmuch as this disease is ordinarily considered to be chronic glomerulo-nephritis, it is of importance to present the features which distinguish them. In order to present these differences graphically and briefly, we have prepared two charts. On the first are shown the essential clinical and pathological findings in the two diseases. On the second are shown the laboratory findings in the normal individual, in chronic glomerulo-nephritis, and finally in our four cases. The addition of amyloid disease does not alter the clinical picture particularly and for this reason this fourth case is reported. There are certain differences in the findings which are obvious and are due to the chronic process which causes the amyloidosis—in this case, syphilis.

In the consideration of these charts certain essential differences should be noted. The most important of these is the absence of the vascular phenomena which form such a prominent part in the clinical picture of chronic glomerulo-nephritis. In nephrosis there is no hypertension, cardiac hypertrophy, retinitis, or anemia. In addition the absence of marked nitrogen retention in the blood, and the change in the serum proteins, should be

emphasized. These are fundamental differences, well correlated with the difference in the pathology of the two diseases, and should serve to distinguish the two.

In order to call attention to this group of cases and to record the apparent beneficial effects of the treatment advocated by Epstein, we are reporting four cases which we have been fortunate enough to observe in the past year. The first three of these fulfill fairly well the clinical criteria of chronic nephrosis. The fourth was diagnosed nephrosis pre-mortem and is reported to show the resemblance between amyloid disease of the kidney and

COMPARISON OF CHRONIC GLOMERULO-NEPHRITIS AND CHRONIC NEPHROSIS		
I. CLINICAL		
	CHRONIC NEPHRITIS	CHRONIC NEPHROSIS
Etiology	Acute infections	Metabolic
Renal Pathology	Inflammatory. Primarily vascular with infiltration and hyalization of glomeruli, and secondary tubular atrophy.	Degenerative. Primarily tubular with minimal glomerular changes.
Symptoms		
Edema	Frequent	Absent
Anorexia	Common	Present
Polyuria	Moderate	Present
Nocturia	Present	Present
Hypertension	Marked secondary type	Absent
Cardiac hypertrophy	Moderate	Absent

Treatment	Low protein, salt poor diet	High protein, salt poor diet

Chart I. Comparison between chronic glomerulo-nephritis and chronic nephrosis as to etiology, pathology, symptoms, prognosis, treatment.

chronic nephrosis. Of necessity only brief protocols could be submitted, only the essential positive findings being given. The laboratory data are recorded on Chart 2. For the privilege of reporting three of these we are indebted to Dr. S. P. Rees and Dr. E. J. Huenekens. We are also indebted to Dr. M. H. Nathanson for aid in the diagnoses.

CASE RECORDS

CASE 1. D. B. Female, single, aged 21, Greek. Seen with Dr. S. Weisman.

Present Complaint—Edema of ankles and weakness for eight months.

Past History—Mumps, measles, typhoid in childhood. Influenza three years ago.

Present Illness—During the war patient lived in Greece and was on a very restricted diet, particularly lacking in protein. Since influenza has felt weak and tires easily. First noticed edema of ankles three months after coming to this country. Eight months ago first noticed swelling of legs and neck and since then swelling of the whole body varying at times. Feels weak and remains in bed most of the time. Occasionally dizziness and headache and morning

nausea. Has been on a restricted protein diet consisting chiefly of milk for past eight weeks without apparent benefit.

Physical Examination—Head and neck negative except for slight hypertrophy of tonsils. Lungs normal. Heart normal in size and shape with no evidence of abnormality. Abdomen shows palpable liver and spleen, the former being almost normal in size, the latter somewhat enlarged. Ophthalmoscopic examination negative. Physical examination showed no other evidence of pathology other than a very moderate edema of the ankles which had almost disappeared in a short time.

Laboratory Findings—Shown in chart two as Case 1.

Treatment—Placed on a diet from 200 to 240 grams protein, 40 to 60 grams fat, and 200 grams carbohydrate daily, making calories from 1,600 to 2,400 daily. Fluids restricted to 1,800 c.c. During a short time of observation, the albumin dropped from 8 to 2 grams per liter of urine, but edema had practically disappeared before dietary treatment had begun. Patient still living and apparently well at the last report.

Summary—Case of a young girl, showing massive albuminuria, casts, edema, but no red blood cells in the urine, no hypertension, cardiac enlargement, retinitis, anemia, or retention of metabolites, normal P. S. P. Basal metabolic rate minus 25.6 per cent (?). Serum shows reversal of

Present Illness—Eight months ago he first noticed swelling of his feet. He felt perfectly well otherwise. This lasted a month then receded. Later it began again, advanced up his legs. He went into a hospital at Spokane, Wash., where he was treated for nephritis for several months without any improvement. After coming to Minneapolis, the swelling became rapidly worse, finally involving all parts of his body, especially his abdomen. He was tapped several times without any relief. At the present time in addition to the swelling he has palpitation of his heart, dyspnea, and anorexia.

Physical Examination—Marked edema of entire body including lids and face. Scars on neck, forehead, legs, abdomen, chest, some deep, some superficial.

Head: Mouth shows considerable dental caries and pyorrhea. Throat is reddened, tonsils somewhat inflamed. Lips are cyanotic. Axillary glands are palpable. No other glandular enlargement. Neck is negative. Heart shows no definite evidence of abnormality. Teleoroentgenogram shows its size to be well within normal limits. Lungs give evidence of bilateral pleural effusion. This is confirmed by roentgenograms. Abdomen is distended with definite signs of fluid. Liver and spleen not palpable. Back shows edema. Extremities show marked edema. Ophthalmoscopic examination negative.

Treatment—July 12—Diet instituted of 1,000 c.c. milk per 24 hours, one ounce magnesium sulphate daily, hot packs; later put on low protein salt free diet. Paracentesis abdominis was done with removal of 1,600 c.c. milky fluid. Treatment continued five weeks with marked increase in edema and gradual progress in the symptoms. Patient became extremely weak, had acidotic breath and general condition very poor.

August 28th—Placed on diet of 200 grams protein, 70 grams fat and 150 grams carbohydrate fluids limited to 1,000 c.c. between meals and 3 grs. thyroid extract given t. i. d. Within two days output rose from 200 c.c. to 700 c.c. per twenty-four hours. Appetite which was completely gone, restored. Patient brighter, condition greatly improved.

September 5th—Albuminuria reduced from 7.5 to .75 per cent. Output greatly exceeds intake.

September 15th—Serum albumin was 4.4 per cent, globulin 1.87 per cent, total 6.28 per cent. X-ray examination and physical were essentially negative except for slight edema along tibiae and slight albuminuria. Blood chemistry and P. S. P. were normal. Was well for three months after leaving hospital, was then lost sight of and has since been reported as dead. Unable to confirm report or discover cause of death.

Summary—Case of a male Chinese, showing tremendous edema and anasarca, massive albuminuria, casts, rarely red blood cells in the urine, no hypertension, cardiac hypertrophy or retinitis, no marked retention of metabolites, no marked reduction in P. S. P. Serum shows reversal of normal albumin-globulin ratio with evidence of lipemia. While under treatment for five weeks with low protein salt free diet patient becomes progressively worse. Institution of high protein fat poor diet with thyroid extract, is followed by marked sudden improvement until almost completely recovered.

CASE 3. M. G. Male, white, two and a half years old.

COMPARISON OF CHRONIC GLOMERULO-NEPHRITIS AND CHRONIC NEPHROSIS

Chart II. Essential laboratory findings in the normal, in chronic glomerulo-nephritis, in three cases of chronic nephrosis, and in one case of amyloid kidney.

normal albumin-globulin ratio but with normal total percentage. Cholesterol of blood increased. Wassermann negative.

CASE 2. S. C. Male, aged 34, married, Chinese. From the Minneapolis General Hospital, service of Dr. S. P. Rees.

Present Complaint—Swelling of the whole body and loss of appetite, weakness.

Past History—Six years ago had a series of multiple infections which had to be incised, leaving scars. This is evidently common amongst Chinese. Three years ago had an illness which caused him to be very dyspneic for a short while but this has since disappeared. He had attacks of fainting during this illness. Otherwise no history of past illnesses is obtained.

Minneapolis General Hospital, service of Dr. E. J. Huene-kens.

Present Complaint—Swelling of face, legs, feet.

Family History—Father died of pulmonary tuberculosis. Twin to patient still-born.

Past History—No previous illnesses whatever.

Present Illness—Mother first noticed swelling of feet and legs one week before admission. No other symptoms.

Physical Examination—No abnormalities except generalized edema of marked extent. The heart and lungs are normal. There is fluid in the abdomen.

Laboratory Findings—Given in Chart 2 under Case 3.

Treatment—Low protein salt free diet for twenty-five days with suitable measures for increasing output of fluid. No improvement whatsoever. Then placed on high protein diet. Two weeks later tonsillectomy with uneventful convalescence. High protein diet continued for four weeks without sign of improvement. During this period he was also given small doses of thyroid extract.

Disease was progressive and patient finally died.

Post-mortem—By Dr. K. Ikeda: Milky effusion in peritoneal and pleural cavities. Generalized edema. Small areas of broncho-pneumonia of recent date in both lungs. Left kidney weighs 72 gms., right, 77 gms. Capsules stripped readily, cut surface pale, swollen and cloudy. Markings well preserved.

Post-mortem Diagnoses—Chronic nephrosis. Generalized anasarca.

Summary—Male child with history of edema without other symptoms. Laboratory findings are marked albuminuria, with rare red blood cells in the urine. Blood shows no anemia, no retention of metabolites, but definite cholesterinemia, and a reversal of the normal albumin-globulin ratio. Treatment by both low protein and high protein diet together with small doses of thyroid extraction was unsuccessful. Post-mortem showed nephrosis of kidneys.

CASE 4. M. J. Female, colored, married, forty years of age. Minneapolis General Hospital, from the service of Dr. S. P. Rees.

Present Complaint — Swelling of limbs for past three months.

Past History—Married twice; two children by first husband; no children, second husband. Usual childhood diseases, occasional sore throats and severe headaches.

Present Illness—For past three months has noticed progressive swelling of limbs and for past two weeks the whole body had become swollen. She had had pains in the back for this same period. For two weeks has had burning urination with a yellowish vaginal discharge. Has been perfectly well up to the present except that menstruation had ceased eight months ago.

Physical Examination—Generalized edema, most marked in lower extremities, but present in face also. Pupils react sluggishly. Tonsils cryptic and injected. Teeth show caries and gingivitis. Ophthalmoscopic examination negative. Moist râles bases both lungs but otherwise essentially negative. Heart normal in size but systolic murmur is heard at the apex, not transmitted. There is fluid in the abdomen.

Laboratory Findings—Put on low protein, salt free diet with limited fluids, and then milk diet with no improvement.

After two weeks, put on high protein, fat poor diet for two weeks and edema continued to increase. Course steadily downward with exitus finally supervening four weeks after entrance.

Post-mortem—By Dr. J. C. McCartney. Free fluid in abdominal and left pleural cavity. Numerous old adhesions in right pleural cavity and in pelvis. Root of aorta shows syphilitic lesions. Spleen adherent to neighboring organs, increased in size, and has waxy appearance on cut surface. Scar in middle. Liver shows several scars with masses of fibrous tissue. Kidney, left 300 grams, right 290 grams. Section shows cortical portion thickened, mottled pink and grayish yellow, but the border between the cortex and medulla is sharp. Aorta shows extensive syphilitic lesions.

Post-mortem Diagnoses — Syphilitic aortitis. Multiple gummata of liver and spleen. Amyloidosis of liver, spleen and kidneys.

Summary—Colored woman of forty with history of edema of three months standing. Physical examination reveals only edema and anasarca. Laboratory examinations show marked albuminuria with red blood cells in the urine, marked secondary anemia, positive Wassermann. Blood shows no retention of metabolic products, a moderate cholesterinemia, a reduction in the serum protein with a reversal of the albumin-globulin ratio. Treatment with both high protein and low protein diet were ineffective. Post-mortem reveals an amyloidosis of the kidneys secondary to syphilis.

Discussion.—Edema and albuminuria, which are among the most prominent symptoms of nephritis, are present in all these cases, and they might easily be diagnosed chronic glomerulo-nephritis. The absence of any infectious etiology, of vascular symptoms, of nitrogen retention, together with cholesterinemia and change in the serum proteins, indicates their essentially different character. In Case 1 should be noted the history of prolonged undernutrition which suggests a possible etiological factor. In this connection it may be observed that chronic nephrosis has been compared to "war edema," the etiology of the latter being a lack of protein in the diet rather than a loss of protein through the kidney. The startling effect of the change from a low protein diet to a high protein, fat poor diet with thyroid extract, should be particularly noted in Case 2. The improvement in the patient was so marked and followed so closely upon the change in treatment, that it is reasonable to conclude the latter was the causative factor. The reduced basal metabolism in the first two cases was definite. In Case 2 the reading was made after the patient had been on thyroid extract for a month. It is reasonable to assume, therefore, that it was subnormal originally. Case 3 showed nephrosis at autopsy. The amyloid kidney illustrates the confusing clinical picture produced by pathology

which involves the glomeruli largely as well as the tubules.

Summary.—Chronic nephrosis is a degenerative process of the tubules of the kidney, of unknown etiology, characterized chiefly by edema and albuminuria, but lacking in the vascular phenomena of glomerulonephritis.

Cholesterinemia, reduction of the serum proteins, reversal of the normal albumin-globulin ratio, are found in chronic nephrosis. In some cases there is a reduced basal metabolic rate.

Three cases which fulfill these criteria, and one case of amyloid kidney, which resembles nephrosis in its clinical manifestations, are reported. A high protein, fat poor diet together with thyroid therapy has been found efficacious in chronic nephrosis. The apparent beneficial effect of this therapy in two of the cases is reported.

DISCUSSION

DR. M. H. NATHANSON, Minneapolis: I had an opportunity of seeing the cases reported by Dr. Rigler and they were very instructive. These patients come in with large amounts of albumin in their urine and a marked edema, and on superficial examination, they might easily be considered as cases of true nephritis. On further study, however, certain features of nephritis are found to be absent. These are, chiefly, the cardio-vascular changes, the hypertension, cardiac enlargement and retinal findings. There is, furthermore, little change in the blood chemistry in this

condition. There seems to be little doubt that this is a definite clinical entity.

There may be some question concerning the pathology of nephrosis, but the pathological physiology of the condition is quite clear, at least, in regards to the mechanism of the edema. In this, it differs from nephritis. In nephritis, the kidney glomeruli are damaged, either as a result of infection or as a result of vascular changes in the kidney. The function of the kidney is then reduced, and substances usually eliminated through the kidney, including water and salt, are retained and edema results. In nephrosis an entirely different mechanism is operating. Fluid is normally held in the blood and prevented from passing into the tissues by the osmotic pressure of the blood, which is dependent on the serum proteins present. A reduction in serum proteins will allow fluid to pass from the blood into the tissues. According to Epstein, this is the mechanism of the nephrosis edema. Epstein believes that chronic nephrosis is not a disease of the kidneys, but a metabolic disease involving, especially, protein metabolism. As a result of this perversion in metabolism, large amounts of protein are passed out in the urine. There is a reduction in the serum proteins, and fluid passes out of the blood into the tissues resulting in edema. This edema is entirely extrarenal, and depends on changes in the blood instead of the kidney. It would follow, then, that the logical procedure in treatment would be to attempt to restore the serum proteins to their normal level. It is on this basis that high protein diet has been tried, and many successful results in reducing the edema and improving the patient generally, are reported.

The mechanism in nephrosis is probably closely allied to that present in war edema, which occurred in countries where there was a deficiency of protein in the diet. In this, there would be a reduction in osmotic pressure of the blood due to insufficient protein intake, while in nephrosis it is due to excessive protein loss. One wonders whether in true nephritis with edema and albuminuria, we may not be favoring the production of a similar mechanism, by excessive restriction of protein in the diet, as is so often prescribed in the treatment of nephritis.

While chronic nephrosis is apparently a definite clinical entity, there is still considerable to be learned about the condition. It should be kept in mind in any case of edema and albuminuria. Careful study should be made, especially, if the other usual features of nephritis are absent or present in a minor degree.

DR. E. L. TUOHY: Doctor Hirschboeck and I have studied a number of these cases, and I wish to support everything that Dr. Rigler has brought forth. The pathologists find fault with this classification of chronic nephrosis. In passing, we wish to say that any classification of disease is likely to be illogical and to show overlapping, but unless we do classify disease and our knowledge of disease, we work as inefficiently as a library, were it to function without a catalogue or index.

A case referable to this situation, in my practice, concerns a man who was supposed to have chronic nephritis, but who developed what we classified then as a pseudo-chylous ascites. The literature available at that time was chiefly that of Parkes Weber, and I reported the case as

one of pseudo-chylous ascites. In going over the kidney carefully, with a number of men, whose judgment pathologically and clinically was very good, I became cognizant of the fact that this was a typical nephrosis, with changes in the kidney structure involving chiefly the tubules and the intertubular tissue. Clinically, this patient's course was a counterpart of those in Doctor Rigler's experience.

Eppinger, Huck, as well as Volhard and Fahr, have aided a great deal in the classification of renal disease. As far back as 1912, Eppinger advised higher protein feeding in these cases. It is not uncommon in nephritis to have what the Germans call "ein nephrotischer anschlag," in which we have an overlapping of symptoms, in part typical of glomerular disease and in part, manifestation of a tubular degeneration.

DR. H. T. HELMHOLZ: I should like to call attention to some work that has been done by Doctor Marriott, of St. Louis, in connection with chronic nephrosis in children. The emphasis has been placed, both by the essayist and in the discussion, on the absence of infection in this type of case. In this series of cases, which I think is twenty-seven, he found in the great majority an infection of one of the sinuses. It was shown that the organism that seemed to be the causative factor was the staphylococcus and that the nephrosis disappeared with the drainage of the sinuses. Certainly in this type of case there seems to be a very definite relationship to infection.

DR. LEO G. RIGLER, Minneapolis: With regard to Dr. Tuohy's experience with pseudo-chylous ascites, it may be of interest to note that we found a very milky fluid when we did a paracentesis abdominis on Case 2. His remarks on subacute nephritis are of interest as a critical examination of the cases of subacute nephritis reported by Christian, who does not recognize nephrosis, indicates that some of them certainly belong in this group.

THE PHARMACOLOGY OF CARBON TETRACHLORID

The most recent claimant for recognition as a means of removing hookworms is carbon tetrachlorid. The moderate cost of this chemical has enhanced its popularity. As the product appears in commerce in a variety of forms for use for different purposes, the A. M. A. Chemical Laboratory studied the quality of the market supply and elaborated standards that might serve to identify products suitable for medicinal purposes. As a result of this study, the Council on Pharmacy and Chemistry adopted standards for carbon tetrachlorid medicinal and listed the brands that complied with these standards. The remedy is comparatively safe, though serious symptoms and even death have been reported from its use, especially in patients addicted to the use of alcohol. Pharmacologic investigation has shown that the substance is relatively non-toxic because it is not readily absorbed from the intestinal canal. Severe intoxication results if the drug is introduced into the tissues directly through the circulation, as by inhalation, or if its absorption is favored by the presence of fats or of alcohol in the stomach and intestines. Hence, alcohol and fats—even milk, perhaps—are to be avoided when carbon tetrachlorid is administered.—(*Journal A. M. A.*, April 19, 1924, p. 1268.)

PSYCHO-NEUROSES*

EDWARD J. ENGBERG, M.D.

St. Paul

We have never had a term in our nomenclature so comprehensive in itself and at the same time so expressive of a vast number of conditions which have been grouped heretofore under various titles as the hyphenated word—the psycho-neuroses. This designation includes them all. Our previous classifications have been descriptive, made according to terms which their symptomatology suggested. The word psycho-neuroses is made on an entirely different basis, that of their origin, as revealed by the inherited tendencies of the individuals classified under this term. Many of the conditions now enrolled under this heading have heretofore been regarded as separate entities, such as epilepsy, migraine, hysteria, dipsomania, melancholia, acute mania, the asocial and anti-social types, such as vagabonds and loafers, as well as the criminals and delinquents of all kinds. A definite relationship is now recognized on this basis. An epileptic mother or a spree drinking father very seldom pass on to their offspring the identical conditions from which they themselves suffer, but what they do transmit is their unstable and defective nervous systems of which their own afflictions are merely manifestations.

D. A. Thom and Germa S. Walker, after the study of the ascendants of a large number of epileptics, state, in their opinions, that epilepsy as a disease is not transmitted directly from parent to offspring, but rather it is the nervous system lacking in normal stability that is inherited and the manifestation of this instability may be mental deficiency of all degrees, insanity of various types and neurological and psychopathic disorders.

Our own case histories, with few exceptions, which often on further information turn out not to have been exceptions, are continually corroborating the conclusions just cited.

Concerning the well known laws of Gregor Mendel on inheritance, Voss says: "It is rather strange when a biological law is fully accepted as true both for animal and plant life, that it should fail in its application to man."

Galton's law of ancestral inheritance may also

*Presented before the annual meeting of the Minnesota State Medical Association, St. Paul, October, 1923.

be mentioned as confirmatory of transmitted mental trends. Jelliffe in his book "The Technique of Psycho-analysis," speaking of the unconscious, in the sense of our historical past or ancestry, says that "its influence is to the conscious as a million years is to the present moment."

Looking aside from statistics and conclusions on the subject of inherited tendencies, because one always encounters contradictions no matter how poorly justified they may be, one may cite concrete instances of such inherited tendencies in such celebrated families as that of the Juke family in New York and the Kallikak family in New Jersey.

The Juke family has been traced through nine generations both in their original and in different environments. Stoddard, in his book, the "Revolt Against Civilization," says of this family, "the same feeble-mindedness, indolence, licentiousness and dishonesty showed itself in this family through all these generations, even when not handicapped by the association of their bad family name and in spite of better social conditions."

The same author mentions the Kallikak family as a remarkable example of how superiority and degeneracy are alike rigidly determined by inheritance. Martin Kallikak, a young revolutionary soldier of good stock, had an illicit love affair with a feeble-minded servant girl by whom he had a son. Some years later Martin married a girl of good family by whom he had several children. This is what happened. The children by the woman of good stock all turned out well and founded one of the most distinguished families in New Jersey. On the other hand the descendants of the feeble-minded girl stand out in sharp contrast. Of these 480 have been traced—143 were clearly feeble-minded, 36 illegitimate, 33 grossly immoral, 24 confirmed alcoholics, 3 epileptics, 82 died in infancy, 3 were criminals and 8 kept houses of ill fame.

Examples similar to the Juke and Kallikak family might be duplicated in every community if careful studies were made of the ascendants of the occupants of our penal institutions, our state hospitals for the insane and feeble-minded, as well as the frequenters of our criminal and delinquent courts.

A study of the mechanisms through which this ancestral stream descends is interesting.

We can readily understand that a difference in pigment makes the eyes brown, blue or hazel, hair

black or red, but the problem becomes more complicated when we are asked to explain why one person is brave, another a coward, one cruel, another tender-hearted. Unfortunately there are as yet no anatomical differences in cell morphology which either the highest powered microscope or the most delicate stain is able to recognize between nerve cells which in their reaction exhibit these antagonistic qualities. Yet such qualities are the effect of nerve cell function. They can be explained on no other basis any more than the difference in the color of eyes may be explained in any other manner than by the difference in the degree of the pigment.

To say that the material basis for this variation in qualities which go to form personality and character rests entirely upon biopsychological processes due to evolutionary changes both in structure and function which have been occurring through the eons of time, beginning with the first particle of protoplasm, is not entirely satisfactory or understandable to the most of us.

It is only by a study of the nervous mechanisms which make possible and satisfy the cravings of these biological processes that explanations and foundations begin to appear.

The autonomic nervous system is the primitive nervous apparatus which furnishes the nerve supply of the smooth muscles, visceral and skeletal and all the glandular structures. White, in his book, "The Foundations of Psychiatry," says "this system operates through the endocrine glands and their hormone secretions to bring about balanced interrelations which play a most important part in the integration of the organism as a whole. In other words, the autonomic nervous system registers the organic needs of the organism, the psychological aspects of which are the effects." This same author also says "the function of the cerebro-spinal nervous system is to bring about a satisfaction of the organic needs."

To illustrate the relationship of the two nervous mechanisms, hunger, for example, is an affective craving testifying to an organic need, produced by the action of the autonomic nervous system on the peptic glands furnishing the stimulation to them in the secretion of gastric juice, as well as the stimulation for the contractions of the stomach musculature. The effect of the autonomic nervous function is to register an organic need in the form of a craving in the nerve cells of the brain, the central

organ of the cerebro-spinal system. The result is, that the cerebro-spinal apparatus so relates the organism to its environment as to secure food and thus satisfy the disagreeable sensations which the craving has brought about. In this simple illustration the mechanism of all our instinctive cravings may be explained, such as thirst, sex, need of rest, sleep, exercise, etc. Under normal conditions the physiological needs of the organism are made known through the autonomic apparatus and the cerebro-spinal system finds the means of satisfying them.

In psychological terms, the endeavor on the part of the organism and its lower nervous apparatus for the control of its higher, the cerebro-spinal or what may be called the psyche, creates a conflict.

Out of this conflict the emotions are born. According to White the emotions are the result of cravings which are not for the time being able to secure the pathways of the psyche for their satisfaction. Kempf has aptly described the emotions as the psychological reverberations of the conflict. The nature of the outcome of this struggle determines the character of our emotions as to whether they have a normal expression or are repressed and distorted. They are to the psyche in its natural normal development what exercise is to the body. These cravings, then, and manner of their control on the part of the psyche, constitute personality. It is evident that in any understanding of personality an appreciation of the impressionability and capacity of these two nervous mechanisms is fundamental; a knowledge of the nature and extent of the control on the part of the psyche; the type and intensity of the lower stimuli is all-important. This may be illustrated in a variety of ways. One of the simplest examples may be taken from animal psychology. We all recognize the futility of trying to make an animal enjoy a symphony or appreciate the painting of a Raphael. The external stimuli for its ear and eye may be more acute than yours, but there is lacking the nerve cells in the animal's receiving apparatus to transform these stimuli into appreciation and pleasure. There are no psychological reverberations, so to speak, no emotional thrills as the result of them.

Another example of a different character illustrating a vicious craving and its psychological reverberations: A boy had attacks of epilepsy. Both his father and brother were spree drunkards; under treatment, the epileptic attacks were trans-

formed into spells of agonizing thirst coming on with the regularity of his former epileptic seizures. These entirely strange sensations to the boy disturbed and frightened him even more than his epileptic attacks. The near relationship of these two symptomatically widely different conditions may be seen in the inherited deficiencies of the two nervous mechanisms, abnormal cravings or stimuli as the result of hypertonicities and tensions in the autonomic or lower nervous apparatus, hypersensitiveness in the nerve cells of the psyche or upper as an effect of medication stopping the reaction of the nerve cells in one place perhaps more susceptible to it and the expression of the abnormal stimuli in another location in the psyche less affected.

This case is also interesting in that it shows both the physiological and psychological mechanism or levels involved in spree drinking as well as the variation in response to similar stimuli. In the boy in the first instance, the stimuli expressed themselves in the form of epileptic seizures, then later as sensations of a vicious thirst. The psychological level of the boy also reacted differently from that of his father and brother in that he endured his cravings instead of yielding to them as they did.

We may also find in this case a good example of what has been called the conditioned reflex and understand more clearly the significance of Jelliffe's statement, when he says: "Our historical past, meaning the unconscious, is to our present consciousness, as a million years to the present moment." By the slow process of evolution and the individuation in this process, naturally occurring in different families, both of structure and function, the nervous mechanism in this family was conditioned, that is rendered more susceptible, or, stating it in a different way, predisposed to such reactions because of this historical past. The father and brother perhaps conditioned themselves in a part of their reaction by seeking to satisfy their cravings with liquor; the boy never having been conditioned in this manner of relief, suffered them out.

The psychological reverberations of affective cravings or hypertensions do not always manifest themselves in the same way in the same individual.

The period of life and its changing functional activities may influence them greatly. As an example of this: A patient had severe attacks of migraine coming on regularly at her menstrual

period and lasting for a day. After her menopause the character of her migraine attacks was entirely changed. Instead of the severe pain which she suffered before, she experienced at about the same interval one day of intense mental depression, so severe that she walked the floor, tore her hair and was possessed of strong suicidal impulses. This case is another illustration of the imperfect function on the part of the autonomic nervous mechanism, expressing its vicious stimuli in a different brain localization at another period of life. It also shows the close relationship which exists between physical pain, endogenous in origin, and what may be called physiological emotional disturbances, that is, emotional disturbances in an individual so predisposed or conditioned by inherited tendencies which seem to be independent of environmental influences.

The psychological effect does not always by any means exhibit itself in one severe attack like reverberation. In fact, by far the greater number of psycho-neurotic reverberations may express themselves by more or less continuous rumblings as the constant complaints of such patients frequently demonstrate. A migraine headache may resolve itself into a persistent neuralgic condition, quite general in character, an acute depression may become chronic.

Fortunately in a large number of those so predisposed, the predisposing cause is in itself not sufficient, under favorable physical and social conditions, to disturb the normal harmonious adjustment of these mechanisms. What may be called an exciting or precipitating factor is needed to disturb their balance. From the endogenous standpoint we observe many times the harmful influence of the precipitating factor at the age of puberty when new and powerful stimuli begin to register their effect on the nerve cells of the brain receiving mechanism because of the greater activity of the sex glands and consequent increase of organic needs. We see many children who seem well adjusted up to this period of their lives; but when these new stimuli come in, so necessary to the full development of the normal individual, their higher nervous mechanism does not seem able to stand the strain and the evidence of their overstress shows itself in many directions. This is a favorite period of life for the development of the psycho-neuroses. The condition is comparable to an electric light decoration, where the bulbs containing the delicate

shades required to preserve the harmony in the color scheme are of a lesser candle power than the more glaring colors, and when enough current is used to illuminate the latter sufficiently the bulbs representing the quieter shades may be burned out and thus the harmony of the whole decoration is spoiled. At the climacteric we observe the opposite in reaction. In this period of life the current necessary to make the bright colors shine in their full lustre begins to diminish, their lights grow dim and the illumination, for a while at least, during a period of readjustment, fails in the purpose of the decoration. The bright colors are gone; only the dull, quieter shades remain.

The precipitating factor of exogenous origin appears in a thousand different ways. Anything which lowers nutrition, and in this manner disturbs function, such as focal infections, general infections, et cetera, may contribute to it. In the psychic sphere, one who stammers may only do so when under sudden excitement; a sick headache may require some sort of nervous strain to bring it on. A nervous breakdown occurs as the result of severe stress or sudden shock.

Such predisposed or conditioned patients must be examined from every angle. Heretofore we have contented ourselves with a physical examination, or perhaps a Simon Binet mental test, and when no satisfactory explanation for symptoms could be given we have defended our ignorance by a skeptical and unsympathetic manner towards the patient, and thus have failed of success with him.

We have acknowledged the reality of the pain in migraine, the unconsciousness in epilepsy, but have not appreciated this factor sufficiently in such conditions as hysterical attacks, emotional states and various conduct disorders, because we have not recognized the relationship between them. Such disturbances should be regarded as the effect of dysfunction in the nervous mechanism just as truly as the reactions of pain in migraine and of unconsciousness in grand mal.

In a recent article on the psycho-neuroses, Macfie Campbell has formulated what he considers as essentials in the examination of these patients.

1. He mentions the determination of the functional efficiency of the various systems of the body, such as the cardiovascular, respiratory, et cetera. Among these systems he says two have a very special importance, the central nervous and autonomic

or endocrine systems, because defects in other systems are compensated to a certain degree in a variety of ways, while inferiority in the endocrine or central nervous system strikes in a very fundamental manner at the behavior of the individual.

2. The constitutional equipment of the patient as regards the fundamental emotional reactions.

3. The special experiences in the life of the patient which may have sensitized him to special topics or situations (as in the conditioned reflex).

4. Physiological factors in relation to the mode of life such as excessive work and consequent fatigue, etc.

5. The actual life situation, such as an unsuitable marriage, distasteful work, uncongenial social environment, etc.

The thought may naturally occur that since these things are all so basic and inherent in the patient, this is in the nature of a Calvinistic creed which has foreordained our course generations before we were born. No doubt many of us can remember a time in our adolescence when glaring colors were about the only ones the limited vision of our consciousness could see. The beauty of the more subdued and harmonious hues made no appeal to us. It was only by the intelligent discipline and direction of our parents, and the stimulating influence of a helpful environment, that we finally began to see them. In the light of this later extended vision we were scarcely able to account even to ourselves for our former conduct. Fundamentally we were not changed; we were only balanced by the bringing into action of dormant and undeveloped qualities. There are many individuals whose illumination in consciousness consists chiefly of colors which jar. They seem to antagonize their environment as well as irritate and excite themselves. When these individuals come to the physician they do not complain of these things. It is quite likely they do not realize them, or, if they do, only vaguely, and are not willing to admit the truth even to themselves. They come complaining of most everything else, but never a word of the real cause. They come complaining of headaches, backaches, lack of concentration, sensations of weakness, gas bloating, a general depressed feeling, et cetera. Our first obligation to such patients is to accept the reality of their symptoms. If there is no physical cause, there must be a psychic or, more strictly speaking, physio-psychological one. We should find out what they have been predis-

posed or conditioned to in their family tendencies. It is surprising how the conditioned reflex reaches down from our historical past. Those who have had the opportunity of treating two generations realize this the best.

In our own work we recall many patients whose nervous symptoms in the way of fears, insomnia, chronic apathies, depressions, were just as much family symptoms as the family features. One patient had a fear of being alone. This fear possessed her to such an extent that during a period of twelve years she had never been alone at home or gone out alone. Her grandmother had the same obsession. Another patient at the age of 35 began to manifest certain paranoid ideas with reference to his family and neighbors. The patient's father held the same ideas at the same age. Such illustrations might be multiplied indefinitely.

A very good criterion by which to judge of the prognosis in such cases is by the course these manifestations took in their predecessors. Since they were evidently endogenous in origin, they bear a much more serious import.

The conditioned reflex, whether it comes to us from our historical past or is one of our own acquiring, often gives the key to the symptoms complained of. A young lady suffered a severe depression. By a careful inquiry into her personal history it was found that she quit school during her first year in high school because she could not bear to get up before the rest of the class to recite. Gradually she became so sensitized to such situations that she stayed at home most of the time because of her fear of meeting people. The depression was a natural consequence.

Many such patients come to their physicians fighting phantoms. They have fixed on some physical ailment, some bodily disease from which they imagine they suffer, and very often indeed over a period of months and years they pursue a weary way seeking relief in this manner. These patients are inadequate either in their bio-psychological processes alone or because of life conditions. Very often there is a combination of both causes.

In order to have at least some understanding and appreciation of this class of cases, more attention must be paid in our examination to these physio-psychological mechanisms and their psychic reverberations. We must try to gauge their capacity, search into their conflicts, repressions, fixations,

regressions, compromises, symbolizations, elevations and sublimations in the same painstaking and careful manner in which at present we conduct our physical examinations.

SUMMARY

The psycho-neuroses are definitely related through the individuating evolutionary processes of inheritance.

It is the unstable nervous structure rather than symptoms and types which is transmitted.

In the psycho-neuroses, defect in the nervous mechanism is the primary factor; dysfunction in the endocrine system *per se* should be regarded as secondary.

Special methods in examination such as indicated are an absolute essential.

The success of treatment depends upon our ability to judge the capacity of these nervous mechanisms with reference to the normal; expose their so-called conditioned reflexes, both inherited and acquired, and establish balance and adequacy in their reactions so far as possible.

DISCUSSION

DR. A. S. HAMILTON, Minneapolis: I am glad that in bringing this matter of psycho-neurosis before the society Doctor Engberg has emphasized the importance of mental mechanism, the state of mind, in the production of the multiform symptoms from which these psycho-neurotics suffer. I think we need to be reminded of that quite frequently. I think the tendency is rather the other way, I mean to attach undue importance to bodily states rather than to over-emphasize the mental aspect.

In spite of the fact that attention has been called to this many times, in spite of all this suffering that psycho-neurotics experience, the lot of the psycho-neurotic is still an unhappy one in the medical world. I am sure that to the great majority of physicians, even to this day, the ordinary psycho-neurotic is an unmitigated nuisance and is dismissed as quickly as the physician can or feels that he dare get rid of him.

I do not want to enter into any prolonged discussion as to the relative importance of bodily conditions as against mental states in producing these symptoms. Doctor Engberg has pointed out that the first duty in the study of these cases is to make a careful autonomic study but when that is complete one is not to assume that the whole thing is done.

I think it is quite possible to overemphasize these autonomic conditions.

Psycho-neurotics complain of many things. That is why they are so burdensome to doctors. It takes so long to go over their record and I think I am safe in saying that no psycho-neurotic ever feels that his case has been properly studied or is well understood until he has had a chance to get off his chest every one of his complaints. I know that every one who deals with these patients has had this experience, that the patient will come back to the office and tell two or three things that he had forgotten. They may be to the physician something wholly immaterial but the patient seems to feel that unless the doctor has all this at his command he cannot understand the case satisfactorily.

The first thing, therefore, is the very careful study of the facts in the particular history of the patient, who will lay before you all of his complaints. It is necessary to make a very careful physical examination. As Doctor Engberg has emphasized, when that is done one has usually won the confidence of the patient. The patient may feel in the end that you do not do him any good or have not done him any good but at least when that much is accomplished there has been a very thorough study of the case and the patient has been led to believe that the doctor does actually sympathize with the multitudinous suffering of the individual. He feels you are making an honest effort to cure his troubles and it puts one on a basis which is at least satisfactory.

DR. HENRY WOLTMAN, Rochester: Dr. Engberg has presented this very important subject in a remarkably clear and able manner. On reading over his paper a good illustration of a phobia based on a conditioned reflex occurred to me. A traveling salesman, suddenly and without apparent cause, found himself in such great fear of getting on a train that he had to give up his occupation. He could leave town in an automobile, but could be induced to board a train under no condition. Further inquiry revealed that on his last trip he had suffered from an attack of diarrhea. It also disclosed the fact that many years before his mother had told him that when he was three years of age, she took him on a train where he developed diarrhea, followed by terrific epileptiform seizures. These seizures continued until he was seven years of age. Since then he has been in mortal terror lest these attacks might return. The phobia concerning the train was actually a fear of epilepsy touched off by the recent attack of diarrhea while on the train. The long interval of time that had elapsed left this conditioned reflex somewhat distorted.

The mechanism in some cases is very simple. For example, a woman complained of blindness of three months' duration. Inquiry showed that this blindness had come on very suddenly. One evening as she was looking out of the window, she saw her husband trudging across the field toward the house. Her vision failed at this moment. As she confessed, she hated the sight of her husband and, subconsciously, by becoming blind, excluded him from her life. When this was apparent to her, vision returned.

That comfort and prosperity alone do not suffice to keep us happy is shown by the fact that there are more suicides on warm, bright, and sunny days than there are on cold and gloomy days, also that there are almost no suicides during catastrophes such as the San Francisco earthquake.

The problem of handling the psycho-neurotic, in all but exceptional cases, is the problem of every physician.

May I ask Dr. Engberg whether he gets any help in the analysis of these cases from dreams?

DR. EDWARD J. ENGBERG (closing): I wish to thank the society for the interest with which it has listened to this paper and I wish to thank those who have discussed it so nicely. I am sorry that Doctor Ball was not here to discuss the paper because it is a combined effort on our part to present this subject. The immediate reason for presenting it was twofold. One is that so many of these patients come to us and tell us of the various doctors they have been to, and they say: "So-and-so said it was nervous trouble, but he said there was nothing to do for nervousness." I think it is certainly a mistaken attitude to take. It results in this type of patient leaving the ethical profession and seeking what help can be obtained through other sources. The other reason is the tragedies we still see at times (though not nearly so frequently as formerly)—needless operations on this type of patients which often increase their disability.

In regard to Dr. Woltman's question: we make use of the patient's dreams to help the study of the case whenever possible, although usually we find that other methods of determining the patient's psychic state are more readily accessible and dependable.

PROHIBITION OF NARCOTICS SALE BY INTERNATIONAL LAW

Although the use of "dope" is on the decline in New York and many other cities, the problem of the drug addict will never be solved until its manufacture and sale are entirely prohibited by international law, says *Hygeia* in its May issue.

Ninety-eight per cent of all drug addicts in New York state have admitted frankly that their use of a drug is due to association with other persons who are addicts and that there was no reason, such as disease, which caused them to begin the use of narcotics. The remaining 2 per cent gave various reasons, principally surgical operations or illness.

Those addicts who have developed the habit accidentally, says the magazine editorially, can be relieved by discontinuing the drugs, but those who take narcotics because they are weak personalities have slight chance of being cured of the habit so long as drugs are obtainable.

Morphin is the drug said to be most preferred by Middle West addicts, while heroin takes the lead in the East and cocaine in the South. The availability of the drug seems to determine the nature of the majority of the addictions.

New York has become the center of established underground traffic in heroin, it is explained, and it has developed into a large business with distributing depots in pool-rooms, saloons and gathering places of criminals, and with peddlers developing the trade.

During the past three years, the use of drugs has decidedly decreased, investigations show. Beginners are now rarely found among the addicts taken up by the police. While 10 per cent of the addicts arrested are women, it is believed that the percentage of feminine addicts is much greater, for women seldom make their purchases on the street as do the men.

CONGENITAL SYPHILIS OF THE NERVOUS SYSTEM WITH A REPORT OF JUVENILE TABES IN TWINS*

FRANK WHITMORE, M.D.

Instructor in Medicine, University of Minnesota

St. Paul

H. R. Dean¹ has stated that the gross brain changes due to congenital syphilis are not compatible, as a rule, with the continuance of life. Aside from such accidents as hemiplegias and the like, the nervous system changes naturally divide themselves into two types: those due to anomalies in development which occur before birth and those due to actual pathological changes in the progress of the disease.

W. T. Heiman² advances the hypothesis that the syphilitic infection is transmitted to the embryo during its most important period of development and that the struggle to overcome it takes place both before and after birth. The child may, therefore, display not only all sorts of developmental anomalies, such as mental retardation, even to the degree of idiocy, physical deformation and dystrophies, but actual pathological alterations as well. In these respects only does congenital syphilis differ from syphilis acquired after birth.

The degree to which the fetus is damaged by the infection depends upon several variable factors. Probably the most important is that expressed by Kasowitz' law, that the nearer the infection is to the conception the more severe the effect upon the fetus; the further in point of time, the milder the effect. Raeder³ reports thirty cases of congenital infection and emphasizes the relation of the element of time in the infection of parent and fetus.

It is impossible to judge how frequently the nervous system is involved because only children who survive can be observed. Hochsinger⁴ found 43 per cent of 112 cases exhibited clinical signs of nervous syphilis. Rumpf⁵ observed it clinically in 13 per cent of his cases. If we include the anomalies of development such as mental retardation, insanity, hydrocephalus, epilepsy, Little's disease and psychopathic inferiority, when due to syphilis, along with pupillary phenomena, optic atrophy, chorea, tabes, paresis and diffuse cerebro-spinal syphilis, probably the nervous system is involved

*Presented before the annual meeting of the Minnesota State Medical Association, St. Paul, October, 1923.

in nearly 50 per cent of the cases. The experiments of Marie and Levaditi seem to point toward a difference in the strain of spirochetes causing general paresis and banal syphilis. Their case is not completely proven. Zabriskie⁶ reports banal syphilis in a parent causing general paresis in the offspring.

Perhaps the difference in the manifestations of congenital syphilis may be explained in this way. Infection by a fresh virulent form of syphilis is more apt to cause physical deformity and nervous anomalies in the offspring, while, as the disease in the parent becomes more latent, thus more nearly approaching the time for the development of late nervous syphilis, the physical manifestations may be less marked and the probabilities of developing late congenital nervous syphilis may become more imminent.

Fraser and Watson⁷ comment upon the comparative rarity of the stigmata of syphilis in children suffering from nervous syphilis. Zabriskie⁶ reports an elder sister who displayed notched teeth and no signs of nervous syphilis while the younger brother suffered from general paresis, but was free from the stigmata. The cases here reported at present show few stigmata but suffer from nervous syphilis.

The signs and symptoms which the two cases to be reported present, at present justify a diagnosis of juvenile tabes; however, as a certain number of such cases eventually develop paresis or taboparesis, only the lapse of time will substantiate or reject such a diagnosis.

In the further discussion of congenital nervous syphilis only those phases of the disease which have a bearing on the two cases to be reported will be considered.

The girls, Margaret and Irene, are ten years old. Their father is in a state hospital with general paresis. He acquired syphilis two years before his marriage. He was treated for a year after his infection and has continued his treatment, at intervals, ever since. Their mother has a positive blood Wassermann, has had intensive treatment and shows no clinical signs of nervous system syphilis.

The children both had a skin rash in the first two weeks after birth and both received salvarsan. Three months later their mouths showed some sores and they were given further treatment. This was continued for a year. During this time they seemed quite well.

Margaret was well until she developed pneu-

monia in her second year, followed by pleurisy and a double otitis media. The otitis became chronic and lasted until she was five years old. She did not walk until she was past her second year and then only with the aid of braces. She began to talk at about two and a half years, but her speech was thick and difficult to understand. As a young child she was nervous and irritable and was often troubled with frontal headache. At six years she had an interstitial keratitis which lasted about a year and during this period her eyesight was reduced so that she could only count fingers at two feet. She occasionally walks in her sleep but has no enuresis.

Mental Examination.—In 1921, when she was eight years old, examination by the Stanford Binet Scale placed her mental age at six years and eight months. In 1923, the tests repeated, placed her age at six years and eleven months, an increase of three months in two years. She is in the second grade in school. Aside from the mental retardation there is nothing of importance in her mental condition and no speech defect.

Physical Examination.—She shows none of the stigmata of congenital syphilis except that her height is not quite up to the average. Her ear drums are retracted. Her vision allows her to read fine print with the aid of glasses. The reflex to light and accommodation is present in both eyes. She has a nystagmus in both eyes, most marked in looking to the right, both rotary and horizontal. Her eye grounds show a primary optic atrophy. The fundus is otherwise quite normal. Her reflexes are normal and all present. No muscular hypotonus. Sensation is normal, excepting an area of diminished perception of pain over her nose and the parts of the cheeks adjacent to it.

Spinal fluid examination gives a negative Wassermann reaction, cell count of 22 per cm. and a trace of globulin. Blood Wassermann is positive.

Irene's history is similar to her sister's, regarding infections. While cutting her teeth she developed an ulcerating sore on her mouth, giving her rhagades. At six years of age her mother noticed a marked inequality in her pupils. At seven years she had a corneal ulcer; at eight years, an extensive herpes zoster covering the entire right side of her chest. She gives no history of enuresis, lancinating pains or crises.

Mental Examination.—An intelligence test in 1923 places her mental age at eight years and nine

months, an addition of twelve months over the previous test in 1921. She is in the fourth grade in school and gets good marks in her studies. The examination discloses nothing abnormal.

Physical Examination.—Except for rather coarse hair, rhagades and diminished height, she displays none of the stigmata of congenital lues. Her hearing is good in both ears. Her right pupil is widely dilated and does not react to light; accommodation and the consensual reaction are present in both eyes. Eye grounds are normal. She displays no other abnormal physical findings.

Spinal fluid Wassermann positive, cell count 30 per cm. and a trace of globulin.

The diagnosis rests on comparatively few signs, a positive serology, blunting of sensation over the face in one case and the eye-signs.

Juvenile Tabes.—Ocular symptoms are of especial importance in juvenile tabes, not only because of the frequency with which they occur, but because they are often so specific as to allow interpretation on a luetic basis, of such indefinite complaints as incontinence of urine, lightning pains and gastric crises.

Optic atrophy occurs in between 40 and 45 per cent of the cases. Cantonnet's⁸ series, 53 per cent of 89 cases; Parkers',⁹ 70 per cent of 10 cases; and Marburg's,¹⁰ 33 per cent of 34 cases. It is usually primary in type, but according to Hawthorne¹¹ the nerve head may be involved in the ruin of a choroïdo-retinitis or in a disseminated choroiditis.

Argyll-Robertson pupils are present in about 80 per cent or the same frequency as in adult tabes. When present in a given case they are almost certainly diagnostic of syphilis as they occur otherwise only in rare cases of lethargic encephalitis and in tumors of the mid-brain.

Irregularity and inequality of the pupils are frequently noticed.

The following description of the behavior of Irene's pupils by her mother is valuable for its accuracy. She states that at six years of age the girl's pupils would be of equal size when she arose in the morning. As the day passed, her right pupil (which is the one inactive to light now) would gradually grow larger until they were very unequal. During the ensuing year her pupil seemed to dilate earlier in the day until finally it was constantly large. This type of pupillary inequality, gradually increasing as the day passes, is characteristic of weakness and gradually approaching paralysis

of the reflex arc and it is frequently due to syphilis.

Transitory diplopia and ocular palsies are said to occur late in the disease.

Nystagmus may be due to some obstruction in vision before the child reaches the age at which visual fixation takes place, or it may be due to a lesion in the vestibular pathway.

Failing vision, headaches, lancinating pains, urinary incontinence and crises are among the earliest and most common symptoms.

Headaches are quite common, particularly when there is a visual defect. They are frequently frontal in character, but occasionally they are hemicranial and of the nature of migraine.

Lancinating pains may be mistaken for rheumatism or growing pains. A diagnosis is often difficult, especially if they come on before the eye-signs. If it is remembered that, contrary to the pains in rheumatism, which are most pronounced about the joints, tabetic pains shift from place to place, but always rest in the muscle, or tissues away from the joints, and that handling or moving the parts does not increase the pain, it is easy to distinguish them.

Urinary incontinence may be mistaken for enuresis, especially if it occurs at night. Ammoniacal odor on the clothes of children, if not due to carelessness, is suggestive.

Gastric crises are difficult to diagnose in childhood, especially in the first attacks. The pain usually precedes vomiting and spreads rapidly to the back, lower abdomen and into the groins. Characteristic of a crisis is the fact that after the most intense pain and vomiting, which may last for days, firm palpation of the abdomen elicits no rigidity and does not seem to increase the suffering and that, in spite of it all, the appetite generally remains good.

Parker⁹ gives the average age of onset in his series as 14 years. Cantonnet's⁶ ages averaged 15. Hirtz' and LeMaires'¹² series 14.3. It may occur at an earlier age as in the cases here reported where it was discovered at eight years. The course is slow and protracted, from five to twenty years may elapse in its development. The full blown picture does not usually appear until after childhood. As the disease progresses, ataxia, loss of knee and ankle jerks, sphincter disturbances, muscular hypotonus, sensory disturbances, ulcerations, arthropathies and progressive loss of locomotion supervene. Herpes zoster occurs rather frequently. Probably the lowered re-

sistance of the diseased tissues makes it more easy prey for the offending organism. The pathology is reported as similar to adult tabes.

Mental Retardation.—Kuhlman¹³ thinks that congenital syphilis occurs no oftener in the institutions for the feeble-minded than among the population in general. This may be true and the following is not intended to convey the idea that syphilis is a preponderant factor in the etiology of feeble-mindedness; but given a series of congenital syphilitics, the number of backward children will be much greater than in a similar number of uninfected ones. Hustens¹⁴ reports 7 out of 14 as retarded. Breuer¹⁵ in 42 cases found 11.9 per cent quite normal, 30.9 per cent slightly backward, 42.8 per cent markedly defective and 14.4 per cent idiots. Mott¹⁶ is of the opinion that syphilis may cause feeble-mindedness without gross pathology in the brain. Logically, gross brain defects might be expected to result in intellectual loss. Fraser and Watson⁷ found serological evidence of syphilis in over 50 per cent of feeble-minded cases suffering from paralysis of some type. Convulsive seizures, hydrocephalus, hemiplegia, diffuse cerebro-spinal syphilis, blindness and deafness often accompany feeble-mindedness. Aside from the frequency of such gross pathology, there is nothing characteristic of the type of retardation which syphilis brings about.

Serology.—About 10 per cent of adult syphilitics develop tabes, paresis or cerebro-spinal syphilis, according to Pilcz,¹⁷ who observed some 4,000 luetic Austrian army officers over a period of from ten to thirty years. From an examination of the spinal fluid alone the incidence in children is much higher. A positive Wassermann reaction on the spinal fluid is generally accepted as evidence of nervous system involvement. However, in dealing with known syphilitic individuals, it is best to consider every other abnormal spinal fluid finding in the light of real or potential pathology. Such changes as are displayed by an increased cell count, increased pressure, globulin, goldsol, Pandy and Mastic reactions are evidences of tissue changes. In judging increased pressure it is well to keep in mind that excitement and an increased respiratory rate are likely to bring about a temporary increase in spinal pressure, so that to be accurate it should be taken under anesthesia and measured by a manometer. From the spinal fluid changes alone, Kingery¹⁸ found 28.8 per cent of 52 cases to be abnor-

mal. Jeans¹⁹ 25.8 per cent of 136 children to have positive spinal fluid Wassermann. The effect of treatment upon the serology has been investigated by Breuer,¹⁵ whose findings in sucklings and older children are here quoted at some length. He found the fluids of sucklings who were receiving full treatment to be uniformly negative. The older children's ages averaged eight years and four months and they had been treated until their blood and spinal fluid Wassermann reactions were repeatedly negative after a pause of three months and a provocative salvarsan. In such children he found pathology in the spinal fluid in 73.2 per cent. Many of these children had been the material of a study by Müller and Singer²⁰ three years previously, who from their results advanced the hypothesis that most of the effects of congenital syphilis can be diminished if not removed by competent treatment. Breuer seriously questions these conclusions and believes that the prognosis for the congenitally syphilitic should be made with the utmost caution, notwithstanding the very best treatment. For in addition to the serological changes he was able to demonstrate a distinct deterioration in ten of the children in the Müller-Singer group, which had taken place in the three years that had elapsed between their respective work. It is therefore apparent that a negative Wassermann reaction on the blood and spinal fluid is no longer the criterion for cessation of treatment, for the process may be clinically active and may yet lead to grave limitations, both physically and intellectually, in spite of treatment.

DISCUSSION

DR. J. C. MCKINLEY, Minneapolis: Congenital syphilis, like that acquired in later life, touches on many fields of medicine. The neurologist, as a matter of course, is particularly interested in that group of congenital syphilitics who develop involvement of the nervous system. Since twenty to thirty per cent of luetic children are said to show evidences of one sort or another of neurosyphilis, it is apparent that careful neurologic studies in individual cases will be of considerable aid in solving the diagnostic and prognostic problems which these patients present. This is well shown by both of Dr. Whitmore's cases, in whom the physical signs of syphilis outside of the nervous systems were scarcely more than suggestive, but in whom the neurologic findings were of sufficient prominence, in conjunction with the case histories, to lead to an investigation of the spinal fluid and consequently to a definite diagnosis of syphilis of the nervous system.

Doctor Whitmore has enumerated the more common symptoms and signs of congenital neurosyphilis. His statement implies a fact that should be more generally recognized; that is, congenital neurosyphilis manifests itself in the same way, with minor variations, as adult acquired neurosyphilis. If, then, one has well in mind the various clinical pictures of acquired neurosyphilis, one should have no greater difficulty in the diagnosis and differential diagnosis among children than among adults.

The presence or absence of nervous system involvement in congenital lues in a given case is of more than academic interest. White and Veedor studied a series of 443 cases of hereditary syphilis. They concluded that the earlier treatment was instituted the better the prognosis, and that

where there were clinical or serological signs of affection of the central nervous system, the prognosis was much poorer, even with continuous well controlled therapy, than in those cases where there was no evidence of nervous system involvement.

DR. E. D. ANDERSON, Minneapolis: There are two points in this paper that it seems to me are of particular interest to the pediatrician. I think the general tendency has been for most of us to consider congenital syphilis as largely a physical rather than a nervous condition, but it has been shown in the literature that a very large percentage of the cases develop evidence of nervous syphilis. Jeans, of St. Louis, who has probably done as much work as anybody in this country on this subject, states that in individuals under two years old, having congenital syphilis, forty per cent of the cases show clinical or serological evidence of neurosyphilis, and in thirty per cent of older children with active syphilis, and in twenty per cent with latent syphilis, there is evidence of involvement of the nervous system. He shows that in a third of all congenitally syphilitic children we find evidence of nervous syphilis.

The other factor of interest was the illustration shown in this paper of how the treatment should be started early and not only started early, but carried on over a long enough period of time. Here are two children on whom a diagnosis of congenital syphilis was made within the first two weeks of life and if the treatment had been carried on long enough the result would have been better. I think most of us dread to see a case of congenital syphilis come to us because of the almost universal pessimism as to results that may be obtained. I think some of the work done in the last few years should lead us to believe that this pessimism is not always necessary.

Fordyce of New York, and Jeans of St. Louis, are two men who have probably done the most in this country on congenital syphilis. The reports of their investigations show that a great deal can be done for children if they are gotten early, but they emphasize again and again that treatment must be carried on over a long period of time. They both recommend the combined use of arsenic and mercury. They both favor giving the mercury intramuscularly. The salvarsan should be given either intravenously or intramuscularly. The salvarsan is given once a week, and the mercury treatment is not interrupted when they are giving salvarsan; in other words the two are carried on together.

Ordinarily from three to five doses of salvarsan are given, and then a rest period of four to six weeks, when it is repeated. The mercury is given continuously once or twice a week, unless evidences of kidney irritation occur. This combined treatment is carried on in infants at least a year, and in older children at least six months after all clinical and serological signs are absent. So I think that we should feel that congenital syphilis is not a hopeless proposition when treatment is properly carried on over a sufficient period of time.

DR. H. L. PARKER, Rochester: About two years ago I became interested in the subject of juvenile tabes and was able to gather seven patients in the records of the Mayo Clinic who have had this disease. There are, therefore, many points in Doctor Whitmore's paper that are of extreme interest to me. I have had the privilege of seeing

two patients who have been under more or less intensive treatment in the last two years and in whom the physical signs have remained more or less about the same.

There is one point, however, which is worth noting; that is, the fact that the course of the disease in juvenile tabes is very long and protracted. The patients bearing signs of juvenile tabes may not show any appreciable change in their condition for five, ten, fifteen or twenty years. On the other hand, it is possible that in some patients mental changes take place, whereupon the disease rapidly changes in appearance and progresses from that of a juvenile tabes to juvenile paresis. When once such a patient shows signs of paresis, an early termination of their life is to be expected.

Another point I would like to add and that is the difficulty of diagnosis of some of these cases. Dr. Whitmore has mentioned the fact and has laid stress on the importance of ocular findings. These findings, so far as my study went, were perhaps the most important in the diagnosis. The pupillary changes, with or without optic atrophy and perhaps a few other less marked clinical signs, are perhaps the most commonly found stigmata of the disease. Usually the patient presents very little for the purpose of diagnosis, and as has been pointed out the diagnosis is more often made by the ophthalmologist. Ataxia is relatively infrequent in juvenile tabes no matter how long the disease may have progressed. Finally, I would like to say that in the cases I had studied six had had spinal fluid examinations and in each the spinal fluid Wassermann test was negative. One of these three cases had, however, a cell count of 36 lymphocytes per cubic millimeter. It might be suggested that in those patients in whom the spinal fluid was negative there were few signs of progress in the disease over a period of years; it had come to a standstill.

DR. PAUL BERRISFORD, St. Paul: I was glad to have the opportunity of hearing Dr. Whitmore's paper. This rare condition was called to my attention during post-graduate study, in fact the two cases reported by Dr. Whitmore were first discovered during my work in the eye department of the St. Paul Dispensary.

It might appear out of place that an oculist discuss a neurological paper. Nevertheless, there is a more intimate anatomical association between diseases of the central nervous system and the eye than between the latter and the nose and throat.

From an ophthalmological standpoint I might mention a few points in juvenile tabes that are well worth emphasizing. Unlike adult tabes, juvenile tabes affects the female more frequently than the male, two-thirds of the cases ap-

pearing in girls. Ataxia is 50 per cent less frequent than in adult tabes. Optic atrophy is frequently the only sign in juvenile tabes. Statistics would tend to prove that the earlier the child is affected the more rapid is the progress of the optic atrophy. Fourteen per cent (Contonnet) of the cases of juvenile tabes have other evidences of hereditary syphilis, interstitial keratitis or chorio-retinitis atrophy.

The condition is due to hereditary syphilis, or syphilis acquired in early youth.

From a differential diagnostic standpoint juvenile tabes must be differentiated from, first, Friedreich's ataxia; second, hereditary cerebellar ataxia; third, cerebral lues; fourth, multiple neuritis. Friedreich's ataxia we recognize by the presence of ataxia, disturbances of speech, nystagmus and a family tendency. In hereditary cerebellar ataxia we not infrequently have an optic atrophy and immobility of the pupils, but there is also present ataxia and increased tendon reflexes. Much more difficult is it to differentiate juvenile tabes from cerebral lues, especially when the latter takes on the form of pseudo-tabes leuetica. However, just as in multiple neuritis, we do not find a progressive optic nerve atrophy. Serological and cytological examination is of much value. A positive Wassermann rules out Friedreich's ataxia, hereditary cerebellar ataxia and multiple neuritis.

DR. FRANK WHITMORE: Regarding the question of how much stress is to be placed on serology in children, it is a little bit difficult to answer. I really have not had very much experience with young children. In the literature Williams makes the point that not infrequently in babies, even if they have a distinctly positive syphilis, they may have both a negative Wassermann on the blood and a negative Wassermann on the spinal fluid. That same individual may, within three or five or eight months, develop a positive blood Wassermann and positive spinal fluid Wassermann. In my paper I tried to bring out the fact that a negative Wassermann due to treatment is not necessarily an indication of the cessation of the process. I think that is true and I am sure that in my cases my experience has shown that a negative cerebro-spinal fluid is not an indication that the process is at rest.

However, in a syphilitic individual, one that you know is syphilitic, spinal fluid changes must be looked on in the light of their present pathology or the pathology that may develop later, as Jeans pointed out; he calls it potential pathology. Those changes are increase in pressure, the globulin reaction, the Pandy reaction, and the mastic reaction—these tests indicate tissue changes. I think a great deal of emphasis should be laid on the serology in syphilis.

RUPTURE OF THE KIDNEY: CASE REPORT*

F. G. WATSON, M.D.

Worthington, Minn.

The interesting factor in this case is the unusual way in which it occurred and the fact that what was apparently a trivial accident proved to be most serious and almost fatal.

B. G., a boy eight years of age, was referred to the Clinic on August 10, 1922, by Dr. E. W. Arnold, of Adrian, Minnesota. Patient walked into hospital and was at once put to bed.

He gave a history of having fallen five days before while climbing into a hayloft. In the fall he struck his abdomen on the top of the manger. He was a healthy stout boy of Hollander parentage and had never had any previous illness. He had been seen by another physician following the accident, but his condition then evidently was good as the parents were assured he was not seriously injured.

When admitted he had a pulse rate 132, respiration 30 and temperature 99.8°. The child was extremely nervous and had an anxious expression. On examination he was found to have a pronounced abdominal rigidity, tender all over and quite distended. He complained a great deal of pain, especially in the right lower quadrant of the abdomen. There was a leucocyte count of 15,000 while urinary findings were negative. A diagnosis of traumatic appendicitis was made and operation advised and accepted.

He was operated at 5:45 in the afternoon, two hours after having been admitted to the hospital. Ether anesthesia was used. A high right rectus incision was made. No free fluid was found in the abdomen, but there was a large mass subperitoneal under the liver appearing like a hematoma or an abscess. The appendix was located post-cecal and adherent to the posterior peritoneal wall over the region of the tumor mass which was about the level of the right kidney. The mass was very extensive, hard, and non-pulsating. The appendix, which was freed with great difficulty, was very congested and large with extravasated blood in the walls. It was ligated and removed. The stump was not invaginated owing to the difficulty of bringing up the cecum, but was treated, however, with carbolic acid and alcohol. A trochar was inserted in the mass

but no fluid escaped. On inserting the finger through the peritoneum it was found to be a dense clot and in this area a large portion of kidney tissue was found unattached. This measured about one and a half inches long in its largest diameter and was free from kidney capsule. A rubber tube drain was inserted and the abdomen closed in the usual manner. The operation lasted one hour and fifteen minutes.

The following day his dressing was found to be saturated with urine. The first four days in the hospital his condition was fair until the wound became infected and there was a very disagreeable discharge of urine and pus with separation of the edges of the wound and sloughing. On the seventh day, after consultation and ascertaining that the left kidney was functioning by a phthalein test, and owing to the fact that he would have a permanent urinary fistula, a nephrectomy was decided upon. The kidney was removed in the usual manner with a lumbar incision.

The boy had a very stormy convalescence. Owing to the fact that the entire wound became infected his recovery was slow and at times his life was almost despaired of. He left the hospital on the twenty-sixth day after the first operation and made a speedy recovery from then on.

I take the liberty of reporting this case because of the rather uncommon occurrence of kidney injuries and that the decision between expectant and operative treatment is a momentous one. On this decision the fate of the patient often rests. The treatment may be expectant or operative and Dr. F. S. Watson has reported a series treated expectantly with a mortality of 27 per cent, and another series treated by nephrectomy with a mortality of 22.5 per cent. Still another series of 107 cases were treated by gauze packing, drainage or suture with a mortality of 8.5 per cent. From the above figures it is plain to be seen that there is a school that favors the expectant treatment; another, early operative treatment as a necessary life-saving step.

It is only by a study of a large number of cases reported that one is able to judge the proper procedure. The need of such reports is brought out when we learn that Kusters says he made a report of 7,740 severe injuries, in only ten of which occurred injury of the kidney.

Israel in a large clinic in Berlin reports but one operative case. Judd reported ten injuries of the

*Presented before the annual meeting of the Minnesota State Medical Association, St. Paul, October, 1923.

kidney, only eight of which were confirmed by operative procedure.

It has been noted that in the usual run of cases the first symptoms were severe and probably due to shock and hemorrhage; then there follows a short period of a few days when the patient's condition is somewhat improved; and later developing secondary grave symptoms due to infection, and nephrectomy is indicated.

Nielson says, "so-called expectant treatment is permissible only in cases where local symptoms are insignificant and constitutional ones are absent." All other cases are operative and must, of course, be a somewhat exploratory procedure, resulting in nephrectomy where the kidney is badly torn or suture can be substituted where the injury is not so great. Nielson and Watson have reported a few cases in which they made primary suture and they were able to locate a number of other case reports making a total of fourteen where the primary suture was satisfactory with the exception of two cases. In these two cases a nephrectomy was later required.

SUMMARY

1. While ruptured kidney is not an extremely frequent sequel of trauma to the abdomen it occurs in a sufficient number of cases to justify its careful consideration.

2. While the symptoms are generally grave at onset they may be mild enough to escape notice. Even urinary signs may be lacking.

3. Expectancy may have its place in treatment but in all except those showing a mild reaction operation with pack, suture, or nephrectomy seems the procedure of choice.

DISCUSSION

DR. GILBERT J. THOMAS, Minneapolis: The case that Dr. Watson reports is indeed very interesting and I wish to congratulate him on his report and the outcome of his case.

In 1917 I reported a case of spontaneous or non-traumatic rupture of the kidney. My conclusions were that a rupture in a pathological kidney may occur without trauma. Spontaneous rupture of the kidney probably does not occur without antecedent pathological change. There are many theories as to the cause of rupture from trauma. Some think that the rupture is brought about by the hydraulic pressure in the kidney. Others think that the distended kidney is thrown against the transverse process of the vertebra and ruptured. Another view is that the ribs are pressed into the distended kidney when external trauma is applied. There are many reports of rupture of the kidney secondary to chronic nephritis. These observations have been borne out by autopsy findings.

I recently observed a very interesting condition which is illustrated by a lantern slide. This patient was an old prostatic who had a tremendous amount of residual urine, which had dilated the kidney pelves and ureters. Because of interference with normal kidney function or lack of kidney tissue, this man was uremic and irresponsible. It was impossible to keep him in bed. On one occasion when the nurse was out of the ward, the patient got up and, because of weakness, fell, striking his abdomen and back on a table. Following this a quantity of blood was found in the urine, which continued until the patient died. The clinical cause of death was uremia. At autopsy the right kidney showed a diffuse hemorrhage in the adipose tissue along its anterior aspect. When the pelvis was opened, an area was found on the posterior wall about 3 by 2 cms. which was entirely denuded of mucosa. There was another tear in the mucosa on the posterior wall about 1 cm. in diameter. The left kidney did not show tears and there was no blood in the pelvis. The lantern slide shows the hemorrhage outside of the pelvis. This man did not have a fall of more than a few inches so that the trauma was very slight. This did, however, produce a hemorrhage and did rupture the kidney, although the kidney was partially destroyed by antecedent pathology.

Recently I observed a boy of 10 years who was forcibly thrown against a tree, striking on the right side of his back. He walked home, but that evening a quantity of blood was found in the urine. The physician who was called found a mass in the kidney area. There was no shock. Patient had little temperature and outside of moderate pain was apparently in good condition. The tumor increased in size during the next thirty-six hours and the patient's condition, except for the pain, was good. At times blood was found in the urine. At other times the urine was normal. The patient was carefully watched. At the end of a week the size of the tumor had decreased and continued to do so thereafter.

This is an illustration of injury of the kidney in which the capsule was ruptured. The tumor was caused by bleeding with the formation of a large clot. There was probably little or no urinary leakage. It is possible that the pelvis of the kidney was also injured, as the hematuria was severe.

DR. A. C. MCGEE, Deer River: In my experience I have had quite a number of cases of rupture of the kidney; but what I want to speak of in particular is that there are many of these cases that get well without surgical interference. It is usually characterized of course by the passing of blood in the urine, when the pelvis of the kidney is involved in the rupture, and there is a great escape of urine into the tissues of the lumbar region. But most of these cases will heal spontaneously. It is well, as the Doctor has outlined, when we have symptoms of severe shock and hemorrhage, to treat these cases expectantly.

Many of the cases that have come to me have been from the woods. In the early days we had the woods very close to us, and injuries to the kidneys were very common. Hardly a winter passed that we did not have a case of rupture of the kidneys. Of course many of them terminated in septic infection, and we had to remove the kidney. All I want to stress is that it is not every rupture of the kidney that needs surgical interference.

DR. F. W. METCALF, Fulda: I happened to be fortunate enough to be associated with Dr. Watson in the surgical treatment of this case that he reports. I just want to report an additional one of my own that will be quite a radical contrast to his. Dr. Watson's case had what appeared to be a very trivial injury, with very grave consequence to the kidney. The case that I wish to report was of a young man who sustained what seemed to be a very severe injury, being trampled upon by a horse.

The accident occurred about 6 o'clock. I was called out in the country to see him about 8 o'clock. He showed some abdominal reaction to the injury and a mild amount of blood in the urine. I felt that it was a traumatic kidney of a mild type—concussion resulting in slight bleeding. I saw him again about three hours later. On account of the abdominal pain and to rule out a possible rupture of the bowel with infection, we made a blood count and found that his leucocytes had shown a very rapid increase in the three hours. To be on the safe side operation was advised and accepted. Upon opening the abdomen I remembered a bit of advice from our old friend, Dr. Spalding: "When in doubt about whether a bowel has been ruptured, open the peritoneum under salt solution and watch for bubbles." We did this and no bubbles appeared. We felt that, with the abdomen open, exploration should be made on account of the severe symptoms. On examination we found nothing except a very small injury to the appendix, an area of softening on the side of the appendix about the size of an ordinary pea, which had almost perforated and which we considered was the cause of the rise in temperature and the increase in the leucocytosis. It appeared to be a case of partial and almost complete rupture of the appendix by hydraulic pressure. We felt that by the early operation we had saved the boy a very stormy time. The kidney lesion showed no signs of further difficulty, and after passing a slight amount of blood for a few days, he made an uneventful recovery.

DR. R. E. FARR, Minneapolis: I want to discuss just one feature of this subject, to add a word to what Dr. McGee has said with regard to conservatism. The last case of this kind that we had is a good illustration. The point I want to make is that even though we have a hemorrhage and later an infection from the leakage of urine into the loin, it is not always necessary to remove the kidney. In one case we removed about one-third of the kidney, which seemed to be loose and did not have a good blood supply. In the last case we simply sutured the kidney. It was ruptured across the midline of shortest diameter; and we simply sutured it with catgut and put in a drain. That boy made a very nice recovery, and he has remained perfectly well. Thus I believe if the portions of the kidney look healthy and are supplied by blood it is well to be conservative in these cases.

DR. O. W. PARKER, Ely: I have been very much interested in the paper and in these reports because at the present time we have a case that we are calling rupture of the kidney which we are treating conservatively, as mentioned by the essayist and Dr. McGee and others. This case was brought immediately to the hospital. He seemed to be severely injured and in shock. He had a large lump already formed in the right side over the kidney region. We immediately took an x-ray picture which showed a fracture of the twelfth rib on the right side and a fracture of the ilium, curling it over. Blood immediately appeared in the urine, almost pure blood at the first specimen. But the boy rallied so promptly—he had been hit by a large piece of iron in construction work—that we felt like treating him conservatively and have continued to do so, hoping that we will not have to interfere. He is improving at the present time. The blood has practically disappeared from the urine—a few cells at times. His temperature has remained low; and he has had no chills. Everything is pointing toward a recovery. We are treating him conservatively with the hope that we will get by without surgery.

A SURVEY OF THE MIDWIFE SITUATION IN MINNESOTA*

E. C. HARTLEY, M.D.

Director, Division of Child Hygiene,
Minnesota State Board of Health

RUTH E. BOYNTON, M.D.

Instructor, Department of Preventive Medicine,
University of Minnesota

Minneapolis

The total number of licensed midwives in Minnesota is 118. It has been felt for a number of years, both by the State Board of Medical Examiners and by the State Board of Health, that this number did not actually represent the entire number of women practising midwifery. It has been the hope of both these organizations for some time to make a survey of the state so that a more accurate conception might be had of the number, qualifications and practice of the midwives of the state than was afforded by the list of known and licensed midwives and by the study of the birth records. Lack of means prevented any such study being made until quite recently. The formation, in the summer of 1922, of a Division of Child Hygiene in the State Board of Health provided a program and a budget for just such studies as this, closely related, as it is, to the field of maternity and infancy. A survey of the midwife situation in Minnesota was therefore made during the past summer.

During the course of the survey almost all of the counties of the state were visited; certainly no section of the state was overlooked. A visit was made to all licensed midwives and as many others as could be located. Names and addresses of unlicensed midwives were obtained from birth certificates and from information furnished by physicians, other midwives, and interested citizens. In some instances the names and addresses of licensed midwives were found to be incorrect—the person named in some cases being deceased or in others having moved elsewhere anywhere from one to five years previously. Almost all midwives interviewed were agreeably obliging to the purpose of the interviewers, regardless of whether or not the midwife was properly licensed. Most of them showed some curiosity as to the purpose of the visit, but all were satisfied with the explanation that the state must require the same data regarding the status of those

practising midwifery as it does of those practising medicine or dentistry.

Vital statistics reviewed in this survey were compiled from birth and death certificates over the period. These figures are exclusive of the cities of Minneapolis, St. Paul, and Duluth, which were so exhaustively studied in the recent paper of Drs. F. L. Adair and C. O. Maland. No distinction has been made between births occurring in hospitals and those occurring outside. In the opinion of Mrs. G. C. Pierson, Director of the Division of Vital Statistics for the State Board of Health, no such distinction could accurately be made for the period covered with the figures now available. Such figures from the three largest cities may be accepted, but from elsewhere throughout the state the reporting of births—accurately—has been too exceptional to permit conclusions to be drawn on this point. Two years ago our Vital Statistics Law was amended and a section added providing that all hospitals and institutions in the state make monthly reports to the State Board of Health. The Director of the Division of Vital Statistics says: "However, we did not insist upon such reports at the time as it was not possible for us to check them when received. In November of 1922, however, a clerk was furnished for this purpose and we immediately requested all hospitals to send in a record of all births and deaths which had occurred in the institution during 1921 and 1922. These reports, when checked against the original certificates, revealed that although the birth record was on file it did not contain the name of the hospital. Since November of 1922 monthly reports have been received from hospitals and we have inserted the name of the latter on each original certificate when the latter did not contain its name. This should mean that in the future figures compiled from the original records should be authentic as to the number of births which occurred in hospitals."

Table No. I: This chart shows that approximately 28 per cent of the midwives found and interviewed in the state are without license. This does not take into consideration the occasional, neighborhood midwife of whose activities considerable evidence was found in certain portions of the state. An accurate estimate of the number of this type of midwife and an appraisal of the scope and nature of her activities is beyond the resources of such a survey as this. For example, in the counties of Cook, Lake, and Kittson, in the northern part of the state, no midwives were found, yet an examination of the birth certificates from these counties shows that 30 per cent of the births in those counties are attended by midwives.

In Table No. II it was hoped that a definite relationship between the number of midwives and the percentage of native and foreign born population in a given county would appear. Apparently, however, no such relationship exists, although its apparent absence may be due to the presence of an unknown number of that group of so-called occasional midwives mentioned above. Such a conclu-

sion is born out by Table VIII and its accompanying graph. Here the curve showing the natural increase in the percentage of native-born mothers is practically paralleled by the curve of physician-attended births. On the other hand, the decrease in the number of foreign-born mothers is roughly matched by a decrease in the number of midwife-attended births and by a decrease in the number of births reported by "others" which, in many cases, probably means midwives.

Tables III, IV, and V are a consideration of certain characteristics of midwives as individuals.

Table No. III shows the birthplace of the midwives interviewed, with only 13.7 per cent native born. Table No. IV shows one of the most distinct characteristics of the midwives of the state as a group. Practically 80 per cent of them are over 50 years of age. There is a tendency, of course, for only women of mature years to begin practising midwifery, but this does not entirely explain the situa-

Division of Child Hygiene Minnesota State Board of Health

tion, since the majority of the midwives interviewed began their practice at between 30 and 40 years of age. In interviewing a considerable number of midwives, one cannot help getting the impression that midwives in Minnesota as a group are disappearing, simply because they are not being replaced. The midwives themselves seem distinctly and somewhat sadly conscious of this tendency.

Table V indicates that slightly more than 90 per cent of the midwives interviewed have had a more or less definite training in midwifery. Many of these took their training in a certain St. Paul school of midwives which has long since ceased to exist. The chart also shows the difference in training between the licensed and unlicensed midwives: of the licensed midwives 72.7 per cent had training in a school for midwives, while of those unlicensed only 12.5 per cent had an equivalent training. At the other extreme—of the midwives without training only 1.2 per cent were licensed, while 37.5 per cent were unlicensed.

TABLE VI
NUMBER OF CASES ATTENDED PER YEAR BY MID-WIVES
INTERVIEWED

No. of Mid-wives	No. of Cases per Year	Per cent of Mid-wives per Group	Grades		
			A	B	C
37	0 — 9	32.17	0	1	36
19	10 — 19	16.52	0	2	17
13	20 — 29	11.31	0	0	13
12	30 — 39	10.43	0	0	12
13	40 — 49	11.31	1	0	12
3	50 — 59	2.61	0	0	3
7	60 — 69	6.08	1	1	5
1	70 — 79	0.86	0	1	0
2	80 — 99	1.75	0	0	2
8	100 and over	6.96	1	0	7
115		100.00	3	5	107

In Table VI the amount of work done by individual midwives is indicated. This chart also indicates a rather arbitrary grading of the midwives based upon the evidence furnished in the interviews. Roughly, the grading indicates as follows: Grade A indicates an alert and intelligent woman who answered questions accurately and promptly, who gave evidence of understanding the proper technique of normal delivery, the recognition of obstetrical complications and particularly an understanding of her limitations. They also showed by their personal appearance and their home conditions a high degree of neatness, cleanliness and orderliness. Grade B includes those who failed in one or two respects from qualifying as belonging to group A. The great majority fell into Class C, which includes all those failing to show a proper understanding of the meaning of asepsis, or of the conduct of a normal delivery, and particularly those who apparently had no proper conception of their limitations in the presence of obstetrical com-

plications or who failed to show a basis upon which they would be able to recognize such complications. This group, likewise, includes all of those showing evidences of senility, who were slow and rambling in the answering of questions, or who showed evidences of carelessness and untidiness in the care of their persons or surroundings. It was thought in preparing this chart that a definite relationship might be shown between the grading of a particular midwife and the size of her practice. Thus it was found that only eight midwives of those interviewed

Maternal Deaths in Minnesota*

Division of Child Hygiene Minnesota State Board of Health

had more than one hundred cases a year, and when it was found that eight midwives fell into grades A or B it was thought at first that these probably

represented the same group. When the chart was finally completed, however, it was seen that only one of this group of eight midwives fell into either grade A or B, the remaining seven being class C midwives. It is a question as to just what inference one would be justified in making from this situation.

Table VII shows the maternal deaths over a five-year period. The graph indicates clearly where the emphasis needs to be placed in any campaign for the lowering of the maternal mortality rate.

LEGAL REQUIREMENTS FOR LICENSE General Statutes 1913

4983. *Midwifery licenses.*—A person desiring to practice midwifery in the state, if not already authorized so to do, shall apply to the state board of medical examiners for a license. Such license shall be granted upon the production of a diploma from a school of midwifery recognized by the board, or after examination of the applicant, upon the consent of seven members thereof. Examinations shall be held concurrently with those provided for applicants for physicians' licenses. The fee for a license granted on diploma shall be one dollar, and on examination two dollars. (2302.)

4984. *Renewal, revocation, and refusal.*—All licenses to practice midwifery, heretofore or hereafter issued by the board, must be annually renewed, and a fee of one dollar be paid for each renewal. Licenses may be revoked or renewals thereof refused by the board for unprofessional or dishonorable conduct, or neglect to make proper returns to health officers of births, deaths, puerperal fever, and other contagious diseases. (2303.)

CONCLUSIONS

1. The number of midwives in Minnesota is small. A total of 166 were found, of which 113 were licensed.

2. The number of midwives is decreasing, as shown by (a) the age groups, and (b) by the absolute and relative number of cases attended by them.

3. The amount of work done by midwives varies with the character of the population. It gradually falls off as the proportion of native-born mothers increases.

4. Most midwives are foreign-born; they are a foreign importation not thriving well in this country.

5. Of the midwives interviewed 28 per cent were without license; of the "occasional" midwife probably none is licensed. There is no apparent difference in quality between the work done by the licensed and that done by the unlicensed midwives.

6. Practically all unlicensed midwives are located outside the three large cities. In rural districts, apparently the unlicensed midwife is not interfered with because of her failure to secure a license.

DISCUSSION

DR. F. L. ADAIR, Minneapolis: I am sure we are all very glad to have heard this careful analysis of the mid-wife situation in Minnesota, and I am sure something should be done if possible to eliminate the casual mid-wife, and the Grade C mid-wives. I noticed something of interest in reference to Dr. Boynton's figures, to which I wish to call attention. In considering the number of cases which the different mid-wives handled, there were only eight mid-wives

of Classes A and B, and while only one of these had over a hundred cases, a ratio of 1 to 7; it is noticeable that in the other less qualified group there were in all 107 mid-wives, seven of whom had over a hundred cases a year, which is a ratio of about 1 to 15. Evidently, if figured on this basis the mid-wives of Classes A and B have a better chance of getting more practice than do those in the C group.

The main part of my discussion will be to supplement Dr. Boynton's study by some tabulations which Dr. Maland and I made regarding the midwifery situation in Minneapolis and St. Paul particularly. The first one is a tabulation of the total living births in Minneapolis and the place where the birth took place and the character of the individual who delivered, that is I mean the scientific character, whether physician or mid-wife. In Minneapolis and St. Paul in the last ten-year period there has been a very marked increase in the number of hospital deliveries. It is very peculiar that the percentage is practically the same in the two cities. In both cities the percentage of hospital deliveries in 1913 was a little over twenty per cent. In 1922 the percentage of hospital deliveries had risen to over sixty per cent, approximately 64 and 65 per cent.

* Not including Minneapolis, St. Paul & Duluth

Division of Child Hygiene Minnesota State Board of Health

Not counting the hospital deliveries, but simply figuring on the basis of home deliveries, there has been in Minneapolis during this period of time an increase in the percentage of deliveries done by physicians, though there has been a decrease in the actual number, due to the increased number of deliveries done in the hospital. In St. Paul the condition is not quite the same. There has been an actual

decrease in the number of deliveries in the home by both physicians and mid-wives; but there has been a percentage increase in the number of deliveries by mid-wives. Really the difference in the statistics in the two cities shows that while there has been both an actual and a percentage decrease in the total number of home deliveries done by mid-wives in both St. Paul and Minneapolis, in ratio the deliveries done by physicians as compared with mid-wives has increased in Minneapolis, but decreased in St. Paul.

These are the main points that will be brought out by the tables and the graphs which I shall show on the screen. The factors in the production of the increase in the number of hospital deliveries are difficult to determine. There are probably many factors which contribute to this. One factor has undoubtedly been the increased emphasis placed on prenatal care and maternal welfare.

DR. J. C. LITZENBERG, Minneapolis: I do not know that I can add anything to illumine this subject. There are two or three satisfactory things that I have noted in both of these reports. I had the privilege of reading them both before coming here. Dr. Adair and Dr. Boynton had sent them to me. On the surface it would seem that the mid-wife situation in Minnesota will probably take care of itself in time; that it will be reduced to an inconsiderable number. However, we should not lessen our efforts to bring about the desired result of getting the number of women delivered by mid-wives down to zero.

I am unable to analyze the increased hospitalization as a part of an obstetric problem; but it seems to me that is probably a part of that general tendency to increased hospitalization of cases, which the Secretary of the American Medical Association spoke of last night. That there was too much hospitalization—that certainly does not apply to obstetrics yet. I feel very much gratified that this work is being carried on under the bureau which as you know has been established for the purpose of getting at what the situation is. The work of Dr. Adair and Dr. Boynton has given us considerable information on the mid-wife; and we see it is not dangerous. It is a problem but not a dangerous problem in this state, because it is on the decrease. It is not like it is in some other states.

I think that perhaps an analysis of birth deaths and maternal deaths with mid-wives and physicians in a further study may be rather illuminating. I remember in most of the references which I have had occasion to look up from time to time in this mid-wife problem that two or three investigators have started out with the idea of an investigation to prove that maternal deaths and infant deaths were due to the prevalence of the mid-wife. There was one very illuminating paper by Dr. Williams of Johns Hopkins, who was asked to study this question. His discoveries were such that he turned his paper into a scathing arraignment of the medical profession, because he found in the investigations that the percentage of maternal and infant deaths was very much greater in the practice of physicians than of mid-wives. I hope that further investigation in Minnesota will not substantiate that thing.

The profession of the state of Minnesota is to be congratulated for the fundamental work on these investigations. Of course there are other problems which this bureau is to take up from time to time which will give us something

definite to take up. I do not feel much alarmed about the mid-wife problem here, but I am considerably concerned about the obstetrics practiced by the medical profession.

DR. H. B. ZIMMERMAN, Saint Paul: I would like to ask Dr. Boynton in her final discussion if she thinks—I meant to ask Dr. Litzenberg—that there is a field for properly educated mid-wives and properly trained mid-wives today.

DR. RUTH BOYNTON, Minneapolis: I do not know, but it might be well to let Dr. Litzenberg or Dr. Adair—who have had a great deal more experience—answer that question about the field for properly trained mid-wives. Apparently in sections where there is a large foreign-born population, they have their place. The question is, it seems to me, whether or not there are enough physicians to take care of the obstetrical work in these localities. I think that is especially true in this state in the northern counties where the population is sparse and the distances which have to be traveled by the physicians are so great that they really are unable to take care of the work.

There is just one other thing that I would like to speak of, and that is these births which are reported by others, that is, reported by informants. We noted that there were about twice as many births reported by informants as births reported by mid-wives; it is the opinion of Mrs. Pierson, the Director of the Division of Vital Statistics, that a certain percentage—probably a large percentage—of births that are reported by informants are probably handled not by licensed mid-wives but rather by these so-called occasional mid-wives. It is hoped that we can find some means of determining just exactly what percentage of these births really are attended by mid-wives.

DR. F. L. ADAIR, Minneapolis: To answer Dr. Zimmerman's question, I would say that personally I feel there is no place for the mid-wife in the cities. I think that by proper co-operation between physicians and nursing organizations the mid-wife can be dispensed with very effectively for the benefit of the community. As Dr. Boynton suggested, in sparsely settled communities, rural communities, I still think that mid-wives may have a place and perhaps will for many years to come. But certainly the Grade C and the casual mid-wife should be absolutely eliminated. Grade A and Grade B mid-wives might be relatively safe institutions, but the untrained casual mid-wife and the poorly equipped Grade C mid-wife are a menace to humanity. There can be no question about that in the mind of any one who seriously considers that problem.

DR. J. C. LITZENBERG, Minneapolis: Are there any schools of mid-wifery any more?

DR. RUTH BOYNTON, Minneapolis: I do not think there are many schools at the present time. Most of the mid-wives whom we interviewed had their training in foreign countries. Those who had their training here, as was mentioned in the paper, had gone to this school for mid-wives in Saint Paul; and then a few had attended schools for mid-wives in Chicago; one or two in the schools for mid-wives in Milwaukee. I believe those schools are not running at the present time. There is a school for mid-wives in New York City in connection with Bellevue Hospital. I believe.

A CASE OF ACUTE OSTEOMYELITIS OF THE MANDIBLE

HAROLD E. HULLSIEK, M.D.

Miller Hospital Clinic
St. Paul

Osteomyelitis of the jaw has probably decreased in the inverse ratio to our increase in interest regarding general health, oral hygiene and industrial sanitation. With increased precautions regarding use of toxic agents in the industries comes a decrease in the number of cases of phosphorus necrosis. Early diagnosis and treatment of tuberculosis, typhoid, lues and other conditions which predispose to osteomyelitis have caused a rapid diminution in the number of cases. The substitution of amorphous phosphorus for yellow phosphorus in the match industry has aided materially. The smaller doses and better controlled administration of mercury has done a great deal to eliminate gingivitis and a subsequent osteomyelitis from that cause. The importance of dental care has become well recognized and thus the predisposing factor of carious teeth is not the menace it was in earlier times.

This condition occurs at all ages, depending on the underlying cause, not any particular age being liable. Osteomyelitis of a definite bacterial origin, however, is more prevalent in childhood and adolescence. There are a variety of causes, which may be grouped as follows:

1. Secondary to infectious conditions about the teeth and peridental tissues.
2. By direct extension from suppurative conditions of the soft tissues about the jaws.
3. Toxic agents such as phosphorus, mercury, pearl dust, et cetera.
4. Secondary to the acute infectious diseases.
5. Secondary to osteomyelitis in any other part of the body.
6. Following trauma.

Necrosis of the lower jaw occurs oftener than that of the upper jaw because of the very much more dense bone in the lower and also because of the difference in the blood supply. The superior maxilla has a very rich blood supply with vessels which anastomose freely, while the lower jaw has but two, which sometimes do not even connect with one another. The bacterial form in the lower jaw may be either hematogenous or extend directly from the periosteum through an open wound. In

either case the vessels in the bone subsequently become thrombosed or constricted, shutting off the blood supply to that particular area and causing localized tissue death. If the infection is from the medulla of the bone with a localized abscess in the bone with no outlet, there is more or less of a severe reaction with chills, high temperature and marked pain. On the other hand, if it extends through the cortex so that there is immediately an outlet or if there is an outlet through an old tooth socket the symptoms are not so marked. The destruction of the bone goes on after the abscess has formed and the pocket is either opened and drained artificially or it continues to extend until it involves the entire body of the mandible, and attempts to drain itself either through the tooth sockets or by burrowing its way through the cortex. If these pockets are discovered and drained early extensive involvement of the bone may be prevented. When drainage has been accomplished either artificially or otherwise the severity of the symptoms gradually subsides, the character of the pus changes from that of a thick purulent material to a thin watery discharge much less in volume. New bone is gradually laid down and the dead portions are separated off and become sequestra. The mandible has a tremendous power of regeneration and the entire bone may be developed following the removal of a sequestrum.

Treatment in the acute stages consists of hot, moist dressings, continuously, to increase the circulation and promote localization. Great care must be given to the hygiene of the mouth inasmuch as persons suffering from this condition usually have a marked edema of the jaws and inside of the mouth preventing proper mastication and salivation and coincident cleansing of the oral cavity. Mouth washes should be used very frequently and the mouth swabbed out with applicators containing an antiseptic. Due to the swelling there is very often inability to take food, and, in order to combat the severe toxemia which is sometimes present, fluid should be administered by rectum. Incision of fluctuating areas should be done as rapidly as they are discovered, the incision being made inside of the mouth or outside, depending upon the shortest route to the pus, but inside of the mouth whenever possible, to obviate disfiguring scars. When the swelling begins to subside and the discharge to lessen in volume, probing through the incisions or into the tooth sockets, if the teeth have been extracted, will disclose the presence of carious bone.

This should be treated with extreme conservatism and removed only when completely separated. The fragments will usually show themselves through the drainage openings in the mouth and can be withdrawn quite easily, depending, of course, upon their size. Large fragments will sometimes exist, necessitating enlarging the drainage openings; a cast of the entire lower jaw has been removed in one piece. The removal of the sequestra sometimes extends over several months and cannot be hastened. In milder cases the teeth need not be sacrificed, but when one has made himself reasonably sure that they will tighten up again they may be allowed to remain.

Fig. 1. Radiograph taken November 2, showing no evidence of osteomyelitis.

If they become so loosened in their sockets that there is no question of their being sacrificed they should be withdrawn, as this promotes additional drainage openings and prevents collection of septic material about their roots.

The case which I wish to report was seen by me on October 25, 1923. He is a boy 18 years old, in good health, whose past history is negative. Four

days before reporting to me he engaged in a football game. At that time he received a blow upon the chin, with a slight abrasion. He remembers that while going home from the football game he picked at this abrasion on his chin, with his finger

could not completely close his mouth. The temperature ranged from 100 to 104 during this time. On cleaning out his mouth on October 29th it was thought there was some pus seen exuding from one of the tooth sockets on the right side. A forceps was inserted along the tooth and down to reach into a pocket which extended along the entire right side of the mandible. The forceps was spread and about 2 ounces of pus evacuated with free drainage following this procedure. This cavity was cleaned out daily, the entire mouth toiletted and the cavity irrigated out with Dakin solution several times a day. In the ensuing ten days several more such cavities were found and opened inside the mouth. The teeth at that time were quite loose and the ad-

Fig. 2. Radiograph taken November 27, four weeks after entrance to hospital, showing definite osteomyelitis involving entire mandible.

nail. The next day he had a small red spot on his chin. The following day this was somewhat tender and swollen. When I first saw him he had an area on the point of his chin about the size of a fifty cent piece, red, shiny, swollen and very tender. The glands were swollen under the chin and tender. The entire chin was slightly edematous. His temperature by mouth at that time was 102.8, his pulse 88. I tried to impress upon him the danger of infections about the mouth and nose and sent him to the hospital, where he was put to bed and had continuous hot applications applied to the whole lower half of his face and chin. He grew progressively worse until on October 29th swelling had extended down on to his neck, up to and including the ears, upon his face until his eyes were closed and he

Fig. 3. Same as Figure 2, showing opposite side of mandible.

visibility of extracting them was considered but the patient and his family were quite insistent that this should not be done and that they were sure they would tighten up later on, so the extraction was delayed.

At this time the boy was very toxic, his urine showing albumin and casts; he was unable to swal-

low and was given fluids by rectum continuously. For a week he was delirious most of the time. On November 2nd he was x-rayed and the plate showed a destruction of bone substance around the roots of the lower central incisor and bicuspids. The x-ray diagnosis was peridental-infection with no evidence of osteomyelitis. The same day he was taken to the operating room and two incisions made below the chin in the endeavor to get better drainage from the aforementioned pockets. About this time the swelling began to decrease, he became less toxic and by November 6th his temperature had gradually become normal. He was now taking liquids by mouth and was able to gargle and wash out his own mouth. The urine, which had contained albumin and casts, was now clear. By November 14th he was up in a chair and walking about and on Novem-

with the jaw again acutely inflamed. It was more swollen than when he left the hospital, he was having a great deal of pain and the discharge was increased. He was sent back to the hospital with axillary temperature of 100 and a pulse of 96. The

Fig. 4. Radiograph taken December 19, showing increased bone destruction with loss of teeth.

ber 16th he insisted on going home and was discharged on a protest, with his jaw still somewhat swollen and discharging moderate amount of pus, his temperature 99 and pulse of 80.

On November 25th he was again seen at home

Fig. 5. Radiograph taken March 19, showing a return to normal in horizontal position of bone.

teeth were all very loose at this time, drainage was re-established with a prompt subsiding of symptoms. On November 27th an x-ray was taken which showed a diffuse osteomyelitis of the entire mandible. By December 4th the symptoms had again subsided and although he had a great deal of swelling and some discharge he was allowed to go home.

On December 6th I was called to his home and he was found to be having a moderate amount of oozing from around one of his molar teeth on the right side. He was taken to the hospital in the middle of the night. This tooth was picked out with an ordinary forceps and a profuse hemorrhage immediately occurred from the socket. This socket was packed and the hemorrhage controlled with a great deal of difficulty and he remained free from bleeding during the night and until the following

afternoon, when he began to bleed more than ever. He was taken to the operating room and all his lower teeth were extracted and the sockets sutured together with one suture of plain catgut across the middle of each socket. At this time three or four pieces of bone were removed, one about an inch long. There was no bleeding following this procedure and only a very slight discharge. The swelling gradually subsided and he was allowed to go home on December 14th with a practically normal temperature.

He was seen in the office on January 1st, at which time he had gained back fifteen of the twenty-five pounds that he had lost and had gone back to work. He still has a moderate amount of swelling, but is no longer toxic and his color has improved a great deal. He is eating very well—of course he is embarrassed to a certain extent by his inability to

take very solid food. At this time three or four more pieces were removed through the mouth.

He was again seen on January 11th and four small fragments of bone removed. He was seen twice during February, each time a small fragment being removed. On March 1st another large fragment was withdrawn and one was seen protruding from the opposite side. This latter one, however, was not sufficiently loosened to come away easily and was left until a later date.

He will be seen from time to time and the sequestra removed as indicated and subsequently we hope to have him in such condition that a lower plate may be applied and he can again enjoy life as before.

At the present date, March 20, 1924, fifteen fragments of bone have been removed, varying in size from one-half to four centimeters long.

Rehabilitation in Minnesota

The federal government has done and is doing much for those disabled as a result of their service in the World War. Until recent years little has been done or thought necessary for the immense army of civilians incapacitated by accident or disease. That their rehabilitation is a paying proposition, to say nothing of its humanitarian side, has only recently been proven.

It will be a matter of news to most of our readers that Minnesota was among the pioneers in this rehabilitation activity. In July, 1919, rehabilitation work was begun in Minnesota and those active in the work were called upon to take part in the forming of the Federal Industrial Rehabilitation Act which was passed in June, 1920. Minnesota was one of the few states already organized and ready to avail itself of the federal appropriation authorized by this Act.

The federal Act is another so-called "grant-in-aid" measure and makes available a certain sum to any state which will undertake rehabilitation activities. The federal measure is very broad in its scope and includes residents and citizens of the United States incapacitated by accident or disease.

Our state measure limits its activities to citizens and residents of the state but federal funds are available for the assistance of outsiders.

As the activities provided for are educational primarily a Division of Rehabilitation under the State Department of Education was formed with headquarters at the State Capitol. Provision has been made for expenses incidental to re-education and administration only. No allowance is provided for living expenses of those availing themselves of the provisions of the act so that various local charitable and civic organizations are often called upon for assistance. The revolving fund established by the Knights Templars is available in this connection. The Rehabilitation Division provides re-educational facilities in educational or industrial institutions compensating those providing the training. A staff is maintained for the investigation, advisement and placement of applicants. Often the student continues as an employe after the period of training is completed. Difficulty was encountered in placement of students on account of the reluctance of employers to employ individuals with physical handicaps, fearing an increase in the insurance rate for their employes. This difficulty has been largely overcome by state legislation enacted in 1919, making such rate increases by risk carriers a misdemeanor.

During the last fiscal year which ended July 1, 1923, 178 cases were closed as rehabilitated, 29 of whom were women. Of the 361 cases in the live roll at the end of the year, 58 were women. During the year some 236 new cases were registered. The division cost during the year about \$47,000.00 and the estimated income of those rehabilitated amounted to \$160,000.00.

There are those who object to what they term the socialistic tendencies of the day. The above figures confirm the opinion that this sort of work pays. Physicians especially are in a position to appreciate the need of assistance to individuals who are incapacitated from continuing their previous vocations on account of disease or accident. No one who has not become thus disabled can appreciate the agony of spirit experienced by one who is forced by circumstance to look forward to a future of financial helplessness and dependence. The physician more than anyone else is in a position to assist such individuals by putting them in touch with this newly established Division of Rehabilitation, which will help them to help themselves.

Statesmanship

A medical journal is no place for politics but statesmanship is a subject quite distinct from politics. The trend of affairs at Washington, which is calling forth so much adverse criticism, leads us to express ourselves on the subject.

There are certain issues to the settlement of which it is of vital importance that Congress should direct its best endeavors. This nation has recently emerged from a world conflict which has left the rest of the civilized world in a deplorable condition through the loss of hundreds of thousands of its best men. Our loss on this score was comparatively insignificant and even our financial expenditure, tremendous as it was, has not been serious. What steps have been taken to prevent future international embroilment which may be disastrous? The present difficulty with Japan shows the need of some international medium for settling questions involving international relations.

The public is two to one against a soldier bonus as shown very definitely by the poll conducted by the Literary Digest. Have our representatives in congress carried out the wishes of their constituents by passing the bonus bill? Is the passage of a bonus bill going to aid in the reduction of federal taxation which is the crying need in this country?

We have no constructive measures to offer. That is not our business. It is the business of Congress. And yet perhaps we expect too much of our national legislature composed as it is of doctors, lawyers, merchants, thieves, et al. As former Vice-President Marshall so aptly put it in a recent local address—when we are sick we call a physician, when in financial difficulty we retain the smartest lawyer we can find, but we send to our legislatures men in most instances honest but whose only qualifications as law-makers is their citizenship.

The blame descends for the most part on our own heads in that only a fraction of the voters of the country exercise their franchise. Class distinctions are becoming more and more evident in the selection of legislators so that class affiliation rather than personal ability determines elections.

The outstanding need today in our government is statesmanship. We need representatives and, alas, senators particularly who will legislate wisely and not keep their ears to the ground to detect the trend of factional and class interests. It is high time that statesmanship were reorganized as a profession and means for such professional training provided.

Wanted—statesmen to exercise wisdom in the administration of state, national and international affairs.

COMMUNICATIONS

81 East Madison St.,
Chicago, May 19, 1924.

TO THE EDITOR:

On December 6th, 1923, I read, by invitation, a paper on Cleft Palate before the Minneapolis Surgical Society.

In my illustrations, shown during the lecture, I exhibited a number of pictures showing union established between the maxillary and premaxillary bones. But in the discussion, Dr. Waldron said: "I would like to ask Dr. Brophy one question with reference to bony union. Those of you who have read some of Dr. Ritchie's articles on this subject—and we are sorry that he is not here tonight because we would like to have him present his ideas on the question of preliminary lip closure—Dr. Ritchie says he has yet to see evidence of bony union as shown by the x-ray. I would like to ask Dr. Brophy if he has made any systematic record post-operatively, that is, three or four years after operation, of the presence of bony union by the use of dental films and careful x-ray studies."

Case 1. Fig. 1. X-ray photograph of palate of child of about two years showing perfect union of premaxillary with maxillary bones. All deciduous teeth are in place, though not all fully erupted; permanent central incisors shown in formation.

I had no x-ray pictures with me in Minneapolis to show union of the bones, but I have had hundreds of patients for whom such union has been secured, and others in Chicago and elsewhere have been operating and securing union of these bones most satisfactorily.

In order that I may settle this question in the minds of those who have not seen union in such cases, I am sending to you for publication in your journal, x-ray pictures and photographs of plaster casts of the mouth of a child, taken at the age of a little more than two years. The bone operation, moving into position the protruding premaxilla and uniting them to the maxilla, was done when the child was about three months old; the lip was not done until more than 18 months later because the parents could not come to the hospital; and the soft palate is yet to be closed.

In these illustrations, perfect union of bone is clearly

shown; and a well defined arch with teeth in correct position. All of the deciduous teeth are shown, but some of them are not fully erupted. Two permanent central incisor teeth are in formation and shown in the x-ray. The occlu-

the vomer, move the premaxillæ back and make no attempt to unite them to the maxillæ is unsurgical, cannot produce a normal arch and may be likened to the treatment of a fracture elsewhere without insuring contact of freshened surfaces and immobilization. It is well known that such treatment would result in non-union.

To establish union between the premaxillæ and the maxillæ, such procedure as I have advised must be followed. Those who do not follow this practice will meet with failure—and it is following such failure, I am sure, that Dr. Ritchie's observations have been made.

I have no other motive in this matter than to assist in making known a very important technic in establishing normality of the separated and misplaced bones.

Very truly and fraternally yours,

TRUMAN W. BROPHY.

Case I. Fig. 2. Cast of upper arch, showing teeth in normal position. The first molars and cuspids are not completely erupted. This case shows the value of retaining the tuberosities in normal position, leaving the soft parts only slightly separated and the palate, when united, long enough to close the naso-pharyngeal opening.

sion is good, as will be seen. It will also be seen that the tuberosities are in normal position. The cleft of the soft palate is, consequently, very narrow and abundantly long so when united it will easily close the naso-pharyngeal opening.

I have just returned from California and this is my first opportunity to address you on this subject. However, these illustrations can be duplicated many times from patients of mine and of other surgeons who follow a course of treatment such as I have outlined in this and other papers.

I am satisfied that those who have not seen cases where perfect union has been established between the premaxillary and the maxillary bones, have seen cases which were not properly operated. I wish to reiterate what I said in my Minneapolis paper: The premaxillæ should be moved into place after freshening the surfaces which are to come into contact. The compact bone should be removed and the freshened surfaces of cancellated bone placed in contact and immobilized. When this is done, the soft tissues covering the bones may be sutured with horsehair. To divide

Case I. Fig. 3. Cast of mandible. Shows well formed arch, with eight deciduous teeth erupted.

Case I. Fig. 4. Upper and lower arches in normal occlusion, though molars and cuspids not fully erupted.

OBITUARY

DR. JOHN LANDENBERGER

Dr. John Landenberger died at his home in New Prague, Minnesota, May 13, 1924, of an apoplectic stroke.

Born in Alton, Illinois, September 23, 1850, John Landenberger came to New Prague with his parents when a boy. He was graduated from Bennett Medical College, Chicago, and practiced medicine at New Prague from the time of his graduation in 1875 to the time of his death.

Dr. Landenberger was a member of his county and state medical societies and one of the delegates to the State Association at the time of his death. He was the first president of the Scott-Carver County Medical Society, for which he was always a zealous worker. He was a member of the N. P. Lodge No. 46 I. O. O. F., King Hiram Lodge No. 31, A. F. and A. M. of Jordan, and of the A. O. U. W.

Dr. Landenberger is survived by his widow, two daughters, Mrs. M. C. Campion and Mrs. Carl Fiske, and two sisters, Mrs. Hattie Lampert and Mrs. Catherine Canaries.

The following tribute was paid to Dr. Landenberger in the New Prague Times:

"He was an outstanding figure possessed of a vivid, virile personality, rugged honesty, and strong character. He was ever guided by the highest principles. Possessed of strong convictions on all moot questions, he was never vacillating but always gave voice openly to his opinions. He was always a force to be reckoned with on every public question. Progressive in his views, he was always in the vanguard of any movement tending toward the advancement or betterment of his home community. The life of Dr. Landenberger has left its impress for the better on the history of New Prague."

REPORTS AND ANNOUNCEMENTS OF SOCIETIES

NORTHERN MINNESOTA MEDICAL ASSOCIATION

Monday and Tuesday, August 4 and 5, 1924, have been chosen as the dates for the annual meeting to be held in Duluth. Among the out-of-town speakers who will appear on the program are: Dr. Williard Bartlett, St. Louis; Drs. W. J. Mayo and L. G. Rowntree, Rochester; Dr. C. N. Candler, Fargo; Dr. Theo. Bratrud, Warren; and Dr. C. B. Lewis, St. Cloud.

The annual banquet will be held Monday evening. Plans are also being made for golfing and excursions, either by boat or automobile to Isle Royale, Port Arthur, or the iron range.

Dr. E. L. Tuohy, of Duluth, is chairman of the committee on arrangements for the Duluth meeting. The program committee is headed by Dr. W. W. Will, Duluth.

NORTHWESTERN MEDICAL OFFICERS ASSOCIATION

At the meeting of the Northwestern Medical Officers' Association held May 6, 1924, in Minneapolis, opportunity was afforded those attending to gather together and recount

war experiences. Following the dinner the meeting was addressed by Mayor Leach, of Minneapolis.

The following officers for the ensuing year were elected: Dr. E. M. Jones, St. Paul, president; Colonel C. S. Lister, of the dental department of the U. S. P. H. S., Minneapolis, vice-president; Dr. E. M. Hammes, St. Paul, secretary-treasurer.

MINNESOTA PATHOLOGICAL SOCIETY

"Modern Research in an Effort to Explain the Mechanism of Life" was the subject of the presidential address given by Dr. H. B. Sweetser, Minneapolis, at the annual meeting of the Minnesota Pathological Society, Tuesday evening, May 20, at the Institute of Anatomy, University of Minnesota. Officers elected for the coming year were: President, Dr. E. L. Gardner, Minneapolis; vice-president, Dr. William O'Brien, Minneapolis; secretary-treasurer, Dr. E. T. Bell, Minneapolis.

OF GENERAL INTEREST

Dr. Owen W. Parker was elected president of the Ely Rotary Club at its recent annual meeting.

The first group of students of the Central School of Nursing, University of Minnesota, was graduated March 31, 1924.

Dr. and Mrs. J. A. Evert, of St. Anthony Park, Saint Paul, have returned from a month's trip to New York City and Boston.

Announcement has been received of the marriage of Miss Blanche MacCarthy to Dr. J. C. Michael, of Minneapolis, which took place in Minneapolis, May 17.

Miss Newcombe, Assistant Superintendent of Nurses, Miller Hospital, Saint Paul, has resigned to accept a position as Superintendent of Nurses, St. Luke's Hospital, Duluth.

Dr. John D. Camp, formerly of the Mayo Clinic, Rochester, is now associated with the Massachusetts General Hospital in Boston as a member of the staff of the x-ray department.

Dr. and Mrs. H. G. Franzen, Minneapolis, who have spent the past two months in Los Angeles, Hollywood and other points in California, returned recently by way of Lake Louise and Banff.

The many friends of Dr. Henry Mason Wheeler, of Grand Forks, N. D., will be interested to learn of the arrival of Henry Mason Wheeler, Jr., in April. This news is of particular interest in that Dr. Wheeler has already reached the age of three score years and ten.

Thirty nurses were graduated from St. Mary's Hospital Training School for Nurses, Minneapolis, Monday evening, May 19. Diplomas and medals were presented by Rev. J. H. Gaughan, assisted by Dr. M. J. Lynch. Dr. H. B. Sweetser, chief of staff of St. Mary's Hospital, and Right Rev. J. M. Cleary addressed the graduates.

Monday, May 12, 1924, National Hospital Day, was observed at Mounds Park Sanitarium by the dedication of a bronze tablet presented by the Alumnae of the Mounds School of Nursing, in memory of Miss Esther Kirbach and Miss Anna Dahlby, two graduates of the school, who gave their lives in service to their country during the war.

Work was begun the first of this month on the Red Wing hospital, which will be practically a new institution. An entirely new main structure is to be built to replace the old wooden building, which is to be converted into a nurses' home. The new building was made possible through a gift of \$35,000.00 from Miss Helen Friedrich and C. E. Friedrich, of Red Wing.

Work on the University of Minnesota stadium has been under way for about two months and the contractors expect to have it finished by October 1, so that all home football games can be played on the new field. The contract calls for its completion not later than October 25, a week before the Minnesota-Michigan game, at which the Memorial Stadium will be dedicated to the Minnesota students who have lost their lives fighting for their country.

Announcement is made of a prize essay competition on the subject of "The Interrelationships of Hospital and Community" by the Modern Hospital Publishing Company, of Chicago. Three cash prizes of \$350, \$150 and \$100 will be awarded, and there will be such honorable mentions as may be authorized by the Committee of Awards. Those interested may obtain further information by addressing the Modern Hospital Publishing Company, 22 East Ontario Street, Chicago.

Women internes will be employed at the Minneapolis General Hospital in accordance with a resolution adopted by the Public Welfare Board at a recent meeting that "women's applications shall be placed on exactly the same basis as men, and that the selection of internes shall be so governed." Dr. Mabel Ulrich, who has been a staunch advocate of this policy for the past five years, was in England at the time the vote was taken which brought about the adoption of the policy for which she has worked.

The sixteenth annual commencement exercises of the Mounds School of Nursing conducted by the Northwestern Baptist Hospital Association in connection with Mounds Park Sanitarium, Midway Hospital, and Merriam Park Hospital was held Friday evening, May 16, at the First Baptist Church, St. Paul. Dr. Charles R. Ball, member of the school faculty, and Rev. S. P. Shaw, Sioux Falls, S. D., were the commencement speakers. Diplomas were conferred upon the graduates by Dr. George Earl, president of the Association.

In honor of Dr. George Henry Simmons, for twenty-five years editor of the Journal of the American Medical Association, who has asked that he be retired in his seventy-third year, a banquet will be given Monday, June 9, 1924, at the Congress Hotel in Chicago. Members of the medical profession, educators, scientists and other friends will gather at the banquet to express their appreciation of the outstanding service Dr. Simmons has rendered to medical literature, to medical education, to medical organization, to science, and to the general public welfare.

In connection with Minneapolis Clinic Week, there was held a meeting of secretaries of the various county medical societies. A substantial number of secretaries attended the meeting and an informal discussion of county society affairs took place. Dr. A. E. Benjamin, of Minneapolis, described in some detail the newspaper publicity campaign sponsored by the Hennepin County Medical Society which is about to be instituted. After some discussion it was determined in-

advisable to resurrect the organization composed of county secretaries which has been defunct for several years.

The faculty of the New York Polyclinic Medical School and Hospital, in appreciation of the needs of the general practitioner, has organized a six weeks' course of co-ordinated, intensive, full time instruction, in an endeavor to cover in a comprehensive way the essential points in diagnosis and treatment, in conformity with the present status of general medicine, surgery, and the specialties. The object of this course is to assist the general practitioner in acquiring a practical knowledge of the more recent advances made in medicine and surgery. The present course covers the period between May 19 to June 28, 1924. Information as to date of subsequent courses may be had upon application to the Superintendent. A fee of \$150.00 is being charged for the course.

Minneapolis Clinic Week, May 6-9, 1924, attracted some 130 physicians from without the Twin Cities. The clinics offered were admittedly up to standard but the attendance was below that of previous years. This can be accounted for by the stringent financial situation particularly felt outside of the larger cities and partly by the fact that numerous medical meetings happened to come in May and June this year.

The Minneapolis Health Exposition held in connection with the Clinic Week and sponsored by the Hennepin County Medical Society was an interesting feature. The exposition was put on in a big way and the variety of displays was striking. Mr. Logsdon and a staff of workers carried out the details of the exposition in a most creditable manner and the displays put on by the A. M. A., Minnesota State Board of Health and the University were remarkable. The local physicians furnished their services in connection with the free health examinations which were conducted to acquaint the public with what a medical examination consists of. While local opinion differs somewhat as to the advisability of such expositions, the good in certain lines accomplished by this particular exposition was undeniable.

The Entertainment Committee of the Hennepin County Medical Society conducted during the past winter, a bridge tournament in the society rooms in the Donaldson Building. A series of six matches, one each month, was held. A home to home match was held with Olmsted County, the result being an even score. About sixty members participated with an average attendance of thirty. The members reported some very enjoyable evenings and are looking forward to the series of 1924-1925.

A number of choice prizes amounting to something over \$350.00 were donated by the following firms:

C. Bagstad, Surgical Supplies,

Dezeng Ophthalmoscope and Otoscope.

Donaldson Pharmacy,

Game set in mahogany case.

Noyes Bros. & Cutler,

Baumanometer.

Charles Anderson, Surgical Supplies,

Silver cup.

Physicians Exchange,

Year membership.

Physicians and Hospital Supply Co.,

Set of two Thermos bottles in case.

Syndicate Building Pharmacy.

One hundred cigars.

A. Kneibel Cigar Store.

Fifty cigars.

Benson Optical Company.

Automobile goggles.

Loop Garage.

\$10.00 in trade.

G. Dauphine Tire Co.,

Three \$6.00 purchase certificates.

In addition to these donations prizes amounting to \$70.00 were purchased. The tournament the coming season will be under the chairmanship of Dr. C. A. Boreen, who states that members are now willing to challenge any group in the state.

Under the management of this committee a very successful golf tournament was held last season. Plans are nearly complete for the 1924 tournament and a much larger number have signified their intention to play. Two matches have already been arranged with the Olmstead County Society, two with the Ramsey County Society, and two with the Minneapolis District Dental Society. Several more are being started. All members of the profession in Minneapolis are invited to enter this tournament.

NEW AND NON-OFFICIAL REMEDIES

The following articles have been accepted by the Council on Pharmacy and Chemistry of the American Medical Association:

ABBOTT LABORATORIES:

Procaine-Epinephrine Ampules, 1 c.c. (Abbott).

ARMOUR AND COMPANY:

Anterior Pituitary Tablets, 2 grains (Armour).

Pituitary Tablets, 2 grains (Armour).

Parathyroid Tablets, 1/10 grain (Armour).

LEHN AND FINK:

Sagrotan.

ELI LILLY AND COMPANY:

Uletin (Insulin-Lilly), U-40.

A. LUMIERE LABORATORIES:

Cryogenine.

MALLINCKRODT CHEMICAL WORKS:

Neoarsphenamine-Mallinckrodt, 0.15 gm. Ampules.

Neoarsphenamine-Mallinckrodt, 0.3 gm. Ampules.

Neoarsphenamine-Mallinckrodt, 0.45 gm. Ampules.

Neoarsphenamine-Mallinckrodt, 0.6 gm. Ampules.

Neoarsphenamine-Mallinckrodt, 0.75 gm. Ampules.

Neoarsphenamine-Mallinckrodt, 0.9 gm. Ampules.

Neoarsphenamine-Mallinckrodt, 1.5 gm. Ampules.

PARKE, DAVIS AND COMPANY:

Pituitrin "S" (Surgical).

Ampules Pituitrin "S" (Surgical), 1 c.c.

WELTY COMPANY:

Deodorized Kerosene-Welty.

WILSON LABORATORIES:

Desiccated Parathyroid Substance-Wilson.

Tablets Desiccated Parathyroid Substance-Wilson, 1/20 grain.

Tablets Desiccated Parathyroid Substance-Wilson, 1/10 grain.

NEW AND NON-OFFICIAL REMEDIES

Cod Liver Oil-Squibb.—It has a content of fat soluble vitamin-A which is more than one hundred times that of best quality butter. For a discussion of the actions and uses of cod liver oil, see Useful Drugs. The average dose is 15 c.c. E. R. Squibb and Sons, New York. (Journal A. M. A., April 5, 1924, p. 1123.)

Sagrotan.—A liquid composed of chlorocresol 8 per cent, chlorxylenol 4 per cent, soap 22 per cent, alcohol 9 per cent, and water 57 per cent. Sagrotan is an antiseptic and germicide. The germicidal efficiency of sagrotan is stated to be 2.5 times that of an equal quantity of phenol. While the germicidal efficiency of sagrotan is almost equal to that of compound solution of Cresol U.S.P., it has the advantage over this preparation in that it is almost odorless; also, it is claimed to be less toxic. Lehn and Fink, New York.

Procaine-Epinephrine Ampules, 1 c.c.—Procaine-Abbott. 0.02 gm., epinephrine 0.00004 gm. in Ringer solution, 1 c.c. The Abbott Laboratories, Chicago. (Jour. A. M. A., April 12, 1924, p. 1199.)

Deodorized Kerosene-Welty.—Kerosene which has been treated so as to remove the odorous constituents of commercial kerosene. Because of its solvent action on fats, deodorized kerosene-Welty is proposed for use as a pediculocide and as a means of removing dandruff and the detritus of wounds. Welty Company, Chicago.

Anterior Pituitary Tablets-Armour, 2 grains.—Each tablet contains desiccated pituitary substance (anterior lobe)-Armour (see New and Non-official Remedies, 1924, p. 226), 2 grains. Armour and Company, Chicago.

Pituitary Tablets-Armour, 2 grains.—Each tablet contains desiccated pituitary body-Armour (see New and Non-official Remedies, 1924, p. 226), 2 grains. Armour and Company, Chicago.

Parathyroid Tablets-Armour, 1/10 grain.—Each tablet contains desiccated parathyroid gland-Armour (see New and Non-official Remedies, 1924, p. 224), 1/10 grain. Armour and Company, Chicago.

Pituitrin "S" (Surgical).—A slightly acid aqueous extract of the posterior lobe of the pituitary body of cattle, approximately six times the strength of Solution of Hypophysis U. S. P., containing 0.5 per cent of chlorbutanol as preservative. For a discussion of the actions and uses of pituitary preparations, see Pituitary Gland, New and Non-official Remedies, 1924, p. 225. The preparation is supplied in the form of ampules pituitrin "S" (surgical), 1 c.c. Parke, Davis and Company, Detroit. (Journal A. M. A., April 19, 1924, p. 1265.)

PROPAGANDA FOR REFORM

Matamel.—The statement of composition of Matamel which appears in the advertising of the Newton Laboratories is practically the same as that claimed for Agmel at the time. While Agmel was said to be obtained from the sap of *Agave americana*, Matamel is stated to be derived from another species of *Agave*, namely, *Agave atrovirens* Karw. An analysis of Agmel made for the Council on Pharmacy and Chemistry in 1912 showed the preparation to be a kind of molasses containing a small quantity of formic acid. No alkaloids were found, nor more than a trace of protein matter. At that time the opinion was expressed that the therapeutic value of Agmel was probably nil. (Journal A. M. A., April 5, 1924, p. 1139.)

J. Bernard King's Radium Fraud.—For some years one J. Bernard King has been defrauding the public by selling earth as a cure for all the ills of the flesh under the claim that it was a radium salt. A quietus has been put on King's scheme through the issuance of a fraud order debaring him from the use of the United States mails, not only under his own name, but under the name of the "International Radium Company" and "Radium Products Company." King called his product "Ray-Cura" and claimed that it consisted of radium sulphate found "in the mountains of North America." Ray-Cura was marketed in cloth covered pads which were composed of little sacks of a light colored substance of the consistency of flour. The alleged curative power existed in what Mr. King called radium emanations from this substance. The government investigation brought out that the contents of a pad which sold for fifteen dollars, cost less than six cents. The product was found not even to be radioactive and gave forth no radium emanation. (*Journal A. M. A.*, April 12, 1924, p. 1215.)

Tolysin Omitted from N. N. R.—Tolysin is the proprietary name under which the Calco Chemical Company markets its brand of neocinchophen. The Council on Pharmacy and Chemistry agreed to recognize this proprietary name, first, because the Calco Chemical Company promised to use novatophan (under which name the drug was introduced) or neocinchophen (the New and Non-official Remedies' name) as a synonym, thus avoiding, in a measure, confusion concerning the identity of the substance on the part of physicians, and second, because at that time, the firm was the only manufacturer of neocinchophen in the United States. Before Tolysin was accepted the Council required the discontinuance of the claim that the drug is free from cardiac depressant and renal-irritant action, except when limited amounts are used. Despite this requirement, advertising recently issued for Tolysin implies that it is free from toxicity. Further, the Calco Chemical Company determined to break its agreement to use neocinchophen or novatophan as a synonym. The council has omitted Tolysin from New and Non-official Remedies because (1) it is marketed with unwarranted therapeutic claims, and (2) by the omission of the established synonym, neocinchophen (or novatophan), the physician is likely not to appreciate the character of the drug and its relation to cinchophen. (*Journal A. M. A.*, April 26, 1924, p. 1381.)

PROCEEDINGS OF THE MINNESOTA ACADEMY OF MEDICINE

Meeting of April 9, 1924

The regular monthly meeting of the Minnesota Academy of Medicine was held at the Town and Country Club on Wednesday evening, April 9, 1924, at 8 P. M. The meeting was called to order by the President, Dr. Hamilton. There were 43 members and two visitors present.

The minutes of the March meeting were read and approved.

The following members reported cases:

1. DR. JOHN FULTON (St. Paul) reported a case of Beginning Panophthalmitis Due to Trauma Successfully Treated by Milk Used as a Foreign Protein.

Mr. W. W. T. was assaulted August 5th by being hit a blow with the fist on left eye, driving a piece of the glasses

he was wearing into the eye, severely injuring the cornea, cutting it horizontally through the center down to the limbus on both sides.

I saw him early on the morning of the 6th. The eye-balls and lids were badly inflamed but pupil easily dilated with atropin so that I could get a clear view of the fundus. The evening of that day I was called to his house to see him again and found a very severe septic inflammation starting in; lids and bulbar conjunctiva edematous and many small hemorrhages showing themselves in the conjunctiva. He suffered great pain in the eye throughout the night. He came to the office the following morning with all of the above symptoms increased. The pupil no longer responded to atropin. Edges of the corneal wound white with septic matter. Pus in anterior chamber. All the structures of the eye were badly inflamed. A typical picture of commencing panophthalmitis.

Dr. Paul Berrisford saw the case with me in consultation. He quickly recognized the gravity of the eye condition and strongly urged the milk protein treatment.

The patient was immediately sent to St. Luke's Hospital. On the afternoon of that day he was given 6 c.c. of milk boiled for four minutes; this by the intermuscular route. This produced no constitutional reaction.

The next day Dr. Carl Larsen examined the case with me, and he strongly endorsed the treatment but advised an increase of the dosage, which was pushed up to 12 c.c. with the most gratifying results. Patient's temperature went up to 101. The pupil began to dilate and the intense tenderness of the eyeball, which had been caused by the rapid onset of the septic iridio-cyclitis, had almost completely disappeared.

The intermuscular injections of boiled milk were kept up for several days longer until the eye became quiet, the inflammatory effusion became absorbed, and the eye was soon restored to the condition that it was in before it was injured.

My object in reporting this case to this Society instead of to the Academy of Ophthalmology is to open up the question as to whether or not this same treatment will benefit similar inflammatory conditions in other parts of the body.

Gratifying results from parenteral protein therapy can be abundantly found in the reviews of our medical journals. One of the most interesting reports is from De Andrade, of Rio de Janeiro, in which he reports the most gratifying results in treating postoperative iridio-cyclitis and three cases of gonococcus in which he obtained prompt and complete relief of this most dangerous disease. One of his cases was suffering from urethritis and an old suppurative otitis media, both of which promptly healed under the influence of some therapeutic remedy. He never used more than eight injections and never witnessed any unfortunate effects.

Many foreign proteins are now most popular remedies in the treatment of septic diseases, but milk seems to be the most important, reliable and marvelous in its effect, according to a careful survey of very extensive literature from reliable sources. Schmidt, of Prague, although having had experience with other proteins, in 1815 selected cow's milk for this purpose, assigning for the reason that it was always available, its chemical composition was constant, whereas the composition of the artificial proteins and their derivatives are subject to considerable variation.

There is no doubt as to its wonderful efficiency in acute iritis, iridocyclitis and gonorrheal conjunctivitis. For the former, it quickly relieves the pain and breaks up the synechia which resists atropin. This agent is a powerful prophylactic and for this purpose is being used by many surgeons, with the object of reducing the chances of infection. Many members of my own specialty use it as a preventive in those cases of cataract operation where they have reason to fear septic complications and to aid in relieving septic conditions which still, though very rarely, take place after cataract operations.

Discussion: DR. BROWN: I have used some of these milk injections myself and they do work well in some cases and not in others, and I have been striving to find something that could be standardized better. Dr. Boeckman, I believe, started these injections in St. Paul. Dr. Boeckman got certified milk at first and the injections were very unsatisfactory, so he went down to one of the restaurants and got some of their milk and he then had some very good results.

You are introducing a foreign protein into the system, and that is the thing which turns the case and that keeps these toxins from developing. While milk has done a great deal in these cases, I do not see how it is going to be standardized. Some work is being done on other substances. If we could get another foreign protein which is in the nature of some standardized substance like the vaccine proteins which we introduce for typhoid, and available to everybody in standardized form, I think it would be a fine thing. I think that we are working along the right direction, and that something of that sort will be evolved eventually. There is no question but what the foreign protein turns the tide for the patient and a great many eyes are saved in that way.

DR. ULRICH: I just want to add a word in regard to standardization. The only instance of standardization of therapy in immunity is in the field of soluble poisons—toxins and antitoxins—in diphtheria, botulinus and tetanus. In the field of non-specific protein therapy we are dealing with an unknown chemical substance—protein—and its action on a body in which the laws of weight and mass come into play. So that each individual is a law unto himself. In each instance the dose is experimental and will always be so. There is no way of standardization.

2. DR. FARR (Minneapolis) reported a method of diagnosing so-called "potential" inguinal hernia by means of pneumoperitoneum in instances where the diagnosis could not be made clinically in any other manner except by operation. Dr. Farr stated that he considered that the use of this method, if experience shows that it is safe, will prove an excellent means of clearing up the question of the so-called "traumatic" hernia. Radiograms were shown.

DR. H. P. RITCHIE (St. Paul) gave a talk on some of the Problems of Treatment of Malignancy about the Face, Head and Neck, and illustrated it with numerous lantern slides.

DR. E. S. JUDD (Rochester) read a paper on "Diverticulitis of the Colon," which was illustrated with lantern slides.

Discussion: DR. A. SCHWYZER: Dr. Judd has spoken about the etiology of diverticulitis. This point is as yet all practically in the stage of speculation, and so one is allowed to speculate a little bit, too. Just a general weakness of the

wall of the intestine could hardly be considered an etiological factor because if the diverticulum is not congenital then we must consider it a pressure diverticulum where the mucosa and sub-mucosa are pushed out; in other words a very strong contraction of the intestine might bring it on with a comparatively weak spot in the wall.

Klebs found the diverticula to be located just where the vessels enter the intestinal walls and Dr. Judd has told us that they found diverticula comparatively frequently in fat people. If we now consider that fat especially locates around these entering vessels, we have here a gap in the muscular wall and a lack of resistance at this place during forcible contraction of the gut. I cannot help feeling that these severe contractions of the colon have their effect, especially when people can not always obey nature's call when it should be. Too much and too prolonged resistance to nature's call must therefore be detrimental.

Our old friend, Dr. S., had symptoms that looked like carcinoma of the colon and autopsy showed that he had innumerable diverticula from one end of the colon to the other, which reduced the colon to a hard thick cord.

I think a few meetings ago I mentioned a woman who had discharge of vesical calculi for many months. The patient one day brought calculi in in a box. There were more than twenty of them. They did not seem quite as firm as ordinary calculi, almost somewhat elastic. They were recognized as hardened fecal masses. The cystoscope allowed us to recognize a hole above the trigone. We opened the abdomen, went down along the posterior wall of the bladder until we got to a thick mass which we cut away from the bladder. A small opening into the bladder was closed. Then we dissected this mass from the lower colon which also had a fistulous looking opening into this mass, which was a thick inflamed diverticulum. Apparently the fecal matter had got into this diverticulum, gradually hardened and finally perforated into the bladder at regular intervals.

The wealth of material reported by Dr. Judd is striking for one who sees this class of cases only at long intervals. Perhaps the reason why we do not see more of this condition is that we do not go through our cases as readily with x-ray examination.

The meeting adjourned.

JOHN E. HYNES, M.D.,
Secretary.

POSTOPERATIVE MASSIVE PULMONARY COLLAPSE AND DROWNED LUNG: Simon S. Leopold (Amer. Jour. Med. Sciences, March, 1924).

The attention of the American medical profession is

called again in this article to the postoperative development of massive pulmonary collapse, a condition which is being recognized more and more frequently in this country and is no longer considered a clinical rarity.

The author reports four cases observed by him, which are reported in detail, with roentgenograms and reproductions of the clinical charts. A brief review of the history of the condition is given and speculation indulged in as to its cause, but no new theories are advanced, except that the observer is inclined to think that multiple factors operate in its production, restriction of pulmonary excursion on account of the immobility of the perithoracic musculature, and partial obstruction of the bronchus, due to the formation of mucous plugs in its lumen.

PLANNING A MODERN TUBERCULOSIS SANATORIUM: T. B. Kidner, Consultant on Institutional Planning, National Tuberculosis Association, New York, N. Y. (Modern Hosp., March, 1924.)

Some years ago tuberculosis sanatoriums were of the flimsiest possible type of construction as it was assumed that the patients would almost all be "ambulant." Today it is recognized that every case of active tuberculosis regardless of its apparent severity is a potential "infirmary" case and many hopeful recoverable cases actually require more or less prolonged treatment in bed. The outstanding feature of recent tuberculosis hospital and sanatorium plans is that they approximate more and more the general hospital type. In fact, as regards cases in the "infirmary" stage of treatment, the accommodation provided today in a tuberculosis sanatorium differs scarcely at all from that provided for patients suffering from other diseases in a modern general hospital.

This has naturally resulted in an increase in the cost of construction and calls for increasing attention to details of planning so that unnecessary features may be eliminated. For institutional purposes, tuberculosis patients are classified broadly as infirm, semi-ambulant and ambulant cases. Mr. Kidner believes that at least forty per cent of the accommodations should be arranged for bed cases.

Further, the accommodation for semi-ambulant cases (about thirty-five per cent of the patient capacity) should be so planned that, in case of need, bed care could conveniently be given. About one-fourth only of the total number of patients are likely to be strictly ambulant cases.

Not all the infirm cases need be tray fed; in point of fact, about fifty per cent of infirm patients can usually put on a dressing gown and walk to a local dining room, preferably adjoining the diet kitchen.

It should be possible to wheel any patient from his bed to a porch in fine weather, though it is not necessary to provide porches for all the single and two-bed rooms.

Suitable accommodation should be made for the medical and general administration of the institution. An elaborate operating suite is unnecessary except in a large institution. Public institutions of less than sixty beds or more than two hundred and fifty are not recommended. The former are uneconomical and in the latter it is difficult to secure a personal touch and family feeling between the staff and the patients.

Proper provision must be made for the more modern fea-

tures of sanatorium treatment, heliotherapy, occupational therapy and prevocational training.

Chiefly, effort should be made to meet the latest demands of medical science in the treatment and prevention of tuberculosis.

A. T. LAIRD.

ARTERIOSCLEROSIS AND HYPERTENSION: James O'Hare and Wm. Walker (Arch. of Int. Med., March, 1924).

The authors base their paper on the observation of sclerosis in the larger vessels of the body, and in the smaller vessels, as exemplified by the retinal arteries, in their relationship to hypertension. It has long been noted by observers that hypertension evidently has no relationship to arteriosclerosis existing in arteries of the first and second order of magnitude, and the belief is now definitely established that the relationship exists mainly in the association of a sclerosis of the smaller precapillary arterioles in hypertensive states. The latter vessels can be observed most easily in the fundus of the eye, and in a series of one hundred cases O'Hare & Walker have shown the definite relationship between sclerosis of the retinal arteries and high blood pressure, and that the peripheral vessels play little or no part in hypertension, primarily or secondarily.

In their work nothing was developed to prove that hypertension came first and sclerosis second, or vice versa. Since the retinal vessels are undoubtedly an index of the condition of the small vessels throughout the body, evidences of arteriosclerosis in the smaller retinal arterioles are presumptive evidence of hypertension, and it is suggested that further observation be made by observing the fundus microscopically according to the method of Cohen.

In 50 cases observed, who had definite sclerosis of the peripheral vessels, with normal pressures, the retinal vessels were found to be normal, or with only slight grades of sclerosis manifest, but in 50 cases with definite hypertension, sclerosis of the retinal vessels was marked in every case but two, with an age variation of from 23 years to 85 years. In the latter series, sclerosis of the peripheral vessels was also present from a slight to a marked degree.

AN OUTLINE OF A ROUTINE FOR INSULIN THERAPY: Leon Jonas and J. H. Musser (Amer. Jour. Med. Sciences, April, 1924).

The authors have worked out a very commendable and satisfactory routine for insulin therapy, which will be of distinct value to any one who wishes to undertake the scientific treatment of diabetes mellitus.

In a few pages the authors take up a classification based upon the treatment, rules for treatment, including insulin therapy, the evaluation of a ketogenic-antiketogenic balance, and, finally, tables of food values, height and weight, caloric requirements and dietary measures.

The authors state that there is no pretense at equivocation, that the statements made are dogmatic, with the realization that in an outline of this type there is no place for controversial matter. The subject matter should be of distinct value to the general practitioner who wishes to launch forth on a safe and sane therapeutic regimen.

DILATATION OF THE CERVICAL CANAL THROUGH ARTIFICIAL MUSCLE RELAXATION: (Zentobl. f. Gynak, March 15, 1924):

In some fifty cases where curettage was necessary the author employed local anesthesia. About 60 c.c. of a 0.2% eucaïne solution was injected into the parametrial tissues to the sides of the uterus. The needle was introduced directly under the vaginal mucosa of the portio vaginalis about 1 c.c. below the level of the vaginal vault. The solution was injected slowly, keeping the point of the needle in contact with the cervical musculature. As much as 80 c.c. of a 0.2% eucaïne solution was introduced with no toxic symptoms.

Spontaneous dilatation of the cervix was rapid and in most instances curettage could be carried out without employment of dilators.

If dilators were used the dilatation was painless. General anesthesia was unnecessary.

Postoperative bleeding and discharge were very slight.

Frequently the patients complained of a pressure pain on both sides of the lower abdomen. This pain usually had disappeared on the following day.

ACIDOSIS—A FAULTY DIAGNOSIS: DeWitt H. Sherman and Harry R. Lohnes (Archives of Pediatrics, November, 1923). The diagnosis "Acidosis," implying a distinct and definite disease, has become so common that we wish to present a strong protest against the careless use of this term by the medical profession. It is contended that the term "Acidosis" means merely a set of symptoms, and only a set of symptoms and rarely more, and that it fails to designate the basic factors that may be the cause of this set of symptoms. There are symptoms which have been named acidosis because of the presence of some of the following signs or symptoms, such as: high urinary acidity, acetone on the breath, acetone and diacetic acid in the urine, air hunger, persisting vomiting, stupor, etc., including all of the many signs and symptoms usually enumerated under the heading of "Acidosis." They are symptoms, it may be,

properly so named, but the term "Acidosis" designates a state, not a disease, just as fever indicates a state and not a disease, or just as coma indicates a state and not a disease. If, though, these symptoms-complex are present, it is our first duty to treat the existing condition, and then continue our study to remove, if possible, the underlying cause, and thereby prevent the recurrence of the condition. In the writer's experience, one of the commonest causes of so-called acidosis in children is an infection, and if we search hard enough we will very often find that the symptoms of acidosis are not infrequently associated with involvement of the nasopharynx. Another extremely common cause to explain the frequent so-called "bilious attacks" with its symptoms of acidosis, and sometimes called cyclic vomiting, is enteroptosis or elongated tortuous sigmoid. This occurs in the older children of four to eight years of age, and can generally be promptly relieved. As Talbot recently has told us: "Correct the malposition of the body with or without proper support of the abdominal organs and the bilious or acidosis attacks cease." Foreign proteids, which are toxic to certain children, produce these same symptoms. Among these, egg-white stands out most prominently, and we are appreciating more and more almost every day that there are a great many children who are mildly sensitized to foreign proteids of one kind or another. One or more cases of so-called cyclic vomiting or acidosis have been dramatically cured by relieving eye-strain. We feel now that among careful thinkers the diagnosis of "Acidosis" as an entity is being very generally discarded. The restriction of the diet, by lowering the proteids as well as the fats, may be distinctly harmful because, through malnutrition, it may decrease the child's immunity to infections or lower its resistance to intoxications. The diagnosis "Acidosis" should no longer be used by trained physicians except to designate a state.

R. N. ANDREWS.

REASONS FOR THE FAILURE TO OBTAIN RELIEF AFTER TONSIL AND ADENOID OPERATIONS: I. H. Goldberger (Archives of Pediatrics, November, 1923). Much has been written recently condemning tonsil and adenoid vegetation operations, the authors basing their objections on the failure to obtain relief from the many symptoms that prompted the removal originally of the suspected source of infection. It is the author's contention that children whose catarrhal symptoms do not subside after tonsillectomy and adenoidectomy are in reality suffering from accessory nasal sinus disease. Very little, if any, attention has been paid to the accessory nasal sinuses in children. Sinusitis may occur at any age. The fact that the antrum is the largest cavity at birth may explain its predisposition to infection so early in life. It is the hope of the writer that attention directed to the possibility that the accessory nasal sinuses may be involved, particularly when children fail to improve after tonsil and adenoid vegetation operations, will do much to give relief to these suffering individuals, and will add scientific refutation to the oft-mentioned statement "that children are operated upon needlessly, and without benefit accruing." They conclude that antral infection occurs in over 20 per cent of children with nasopharyngeal catarrh, and that antral suppuration is to be excluded as a possible cause of nasal catarrh in children, especially

when tonsils and adenoid vegetations have been removed. These patients are peculiarly susceptible to colds, which are refractive to treatment. There is anterior and posterior nasal discharge, usually thick, creamy, or green colored, and which seems to continue indefinitely. These children are usually underweight, pale, lack tone and vigor and frequently complain of vague frontal headaches. Lillie claims that a diagnosis is incomplete unless clinical findings and information to be derived from the roentgen-rays examination have been taken into consideration. The consensus of opinion is that operations on the sinuses should be resorted to only after all other procedures have failed.

R. N. ANDREWS.

BREAST FEEDING: Frank Howard Richardson (Arch. of Ped., Feb., 1924). The breast-fed baby has about five times the chance for life and health possessed by the bottle-fed baby. Every mother, given intelligent supervision and instruction, can nurse her baby as long as she and her doctor please. Every mother's milk is good milk, and can be depended upon to agree with her baby, up to the limit of the quantity present. That is, quality is practically never, but quantity very frequently is, at fault. Regular, complete emptying of the breast is essential to continued successful breast feeding. The best emptier of the human breast is the suckling child. The next best, which should be the only substitute tolerated, is the thumb and finger of the mother herself. This procedure should immediately follow the cessation of feeding. The breast-fed baby never over-eats, if fed at reasonably long intervals. This is true not only in breast milk, but also with artificial feeding used to complement the nursing. Laboratory examination of breast milk is worse than useless—it is misleading. So-called colic is usually a symptom of hunger, as can readily be determined by putting the crying child back on the breast. Or, if that is emptied, by offering him a complementary feeding. A rectum full of fecal matter interferes seriously with the appetite for nursing, hence, a soap suppository often greatly facilitates nursing. There is no special diet for the lactating mother, if she will but take a quart of fluid more than usual during each 24 hours. If this fluid is in the form of certified milk, all the requirements will be abundantly satisfied. Adequate rest and sleep are considerably more worth her giving serious thought to than is the question of her diet. Milk never permanently disappears suddenly. Vomiting on the baby's part is as a rule simply an automatic return of a slight excess of milk, or it may be due to a tight band, jolting, etc. It does not mean indigestion. The general practitioner or pediatricist who will not make himself master of the problem of breast feeding has no business to attempt the care and treatment of this age group.

R. N. ANDREWS.

NECESSITY FOR BETTER DENTISTRY FOR CHILDREN: Chas. B. Bray (Arch. of Ped., Feb., 1924). Children's dentistry has been the most neglected field of any of the branches of dental science. If we expect to eliminate focal infection from a dental standpoint, we must begin before it is established, and that certainly is in the early stages of childhood. There is little excuse for dead or ab-

scessed teeth in children, and with the exception of accidents, 99 per cent are caused by neglect or carelessness—lack of education, if you please. Temporary teeth require more care than permanent ones, because they are in a constant state of disintegration. They will not stand as much neglect as will the permanent ones. There are more children going through life today with crippled mouths, hearts, etc., due to neglected teeth and diseased tonsils than from any other cause of which we know. If we eliminate diseased mouths and infected tonsils in children, we will lessen by 50 per cent the child's chances of having the contagious diseases of childhood, such as are contracted or carried in the mouth and nasal passages. The author wishes to emphasize the fact that neglected and diseased teeth play as important a part in the production of systemic disease, and general impairment of health, in children, as we have long known they did in adults, and further, that the best treatment of these conditions is to prevent their occurrence by careful, scientific, and regular treatment of the teeth in childhood.

A. U. DESJARDINS,
MAYO CLINIC, ROCHESTER

THE PATH OF A BEAM OF HARD RAYS IN THE LIVING ORGANISM: Warren and Whipple. (Jour. Exp. Medicine, Dec., 1923.) Using the same experimental methods as previously described, the authors attempted to determine the actual course of a cone of x-rays, applied to the abdomen of a dog. The usual dosage and screening applied in moderately deep therapy were used, the body being protected by lead except for the area to be radiated. After various intervals, following the radiation, the abdomen was opened and the areas of intestine which showed lesions were examined. The lesions were found to be sharply confined to a certain area corresponding to the area radiated and the skin burn. The border between normal mucosa and the ulcerated portion was sharp and it was apparent that there was no dispersion of the rays. The area of intestine affected by the rays indicated that the cone of radiation traveled out from the target along the radii of increasing spheres. If secondary radiation was formed in the tissues it had no injurious effect upon the intestinal mucosa. Even deep in the abdomen the lesions were sharply demarcated, clean-cut, and confined to the same area. The experiments indicate that x-rays, which injure intestinal epithelium, travel in straight lines in the form of a cone, without dispersion or scattering of the primary or secondary rays. The authors can accurately predict the lesions in the stomach and intestine following a measured, confined dose of x-rays.

LEO G. RIGLER.

DIE BEHANDLUNG DES RÖNTGENKATERS MIT HYPERTONISCHEN LOSUNGEN. ZUGLEICH EIN BEITRAG ZUR FRAGE IHRER WIRKUNG—A. Mahnert and H. Zacher (*Wiener klinische Wochenschrift*, vol. 36, pp. 129-130): Holznecht and Sielman have written on the influence of salt on röntgenkater in the form of clysmas and particularly as intravenous injections of 10 per cent salt solution. This has led the authors to report their experiences of treating röntgenkater with a hypertonic solution of glucose.

In a series of cases of carcinoma of the uterus or ovaries which were irradiated, and also in prophylactic irradiation after radical operation in which röntgenkater appears after intensive irradiation, the authors have attempted to relieve the symptoms by intravenous injections of glucose. They use ordinarily 40 cm. of 25 per cent solution and the röntgenkater symptoms (dizziness, vomiting) usually disappeared completely in one-half to one hour. Even 40 per cent solutions were used without disagreeable effects. Injections of glucose before irradiation did not prevent the symptoms of röntgenkater. It was necessary to use not only a hypertonic solution of salt but also a highly concentrated glucose solution. Sielman believes that the solution of salt is the important matter, and Steyskal wonders if it is not a question of the effect of hypertonic solution in general.

A general effect is probably to be expected on the addition of a hypertonic solution in the blood stream as the production of the resulting fluid may be placed parallel to that of a rectal or subcutaneous infusion of an isotonic solution. The change in water content after an injection seems significant as it produces alkali in the blood. This alkali is very important in the treatment of röntgenkater since intensive irradiation changes the relation of acids and bases in the blood, and the tendency is in the direction of acidity. If salt is scarce in the blood a change in the blood is expected. If a hypertonic salt solution is brought into the blood we not only affect the water economy of the organism and the interchange of matter between blood and tissue, but also influence the metabolism of albumin. Perhaps this is the reason that prophylactic addition of salt before irradiation is without effect. Also for the effect of intravenous injection of highly concentrated glucose solution one must assume that as a hypertonic solution they have an influence on the distribution of the stability of the blood in the organism. But at the same time easily oxidized matter is brought in which is influential for the flowing off of the oxidation not only in regard to metabolism but also in burning of albumin molecules. It is these metabolic processes which in irradiation are changed significantly. Perhaps it is these which might explain many changes in the blood and in the urine of patients who have had x-ray treatment. Changes in the blood plasma are very closely connected with metabolism in the tissue after irradiation.

A. U. DESJARDINS.

ROENTGENOLOGIC DIAGNOSIS OF CHOLECYSTIC DISEASE: Carman, MacCarty and Camp (*Radiology*, Feb., 1924).

This paper gives a systematic discussion of the subject,

including a complete bibliography. An attempt is made to correlate the roentgenological findings with the pathology. Cholecystic disease is extremely common, being diagnosed clinically in 5% of all cases seen in the Mayo Clinic in 1922. They found disease of the gall-bladder in 64% of their last 100 necropsies.

The authors describe their technic in detail, the most notable point being that they do not use the Bucky diaphragm in gall-bladder plates. A clear and complete description of the method of interpreting gall-bladder roentgenograms is given with an analysis of the sources of error encountered. The authors are inclined to believe that the "indirect" signs of gall-bladder disease are of little value. Their study is made entirely on the direct signs, that is an enlarged gall-bladder shadow or the presence of gall-stone shadows.

A statistical study of their results in 410 cases coming to operation, on whom a definite roentgen diagnosis was made, is presented. The conclusions from this study indicate: (1) An affirmative definite diagnosis of pathological gall-bladder from the roentgen examination is highly reliable, being correct in 97%. (2) A negative diagnosis is worthless, correct in only 17.4%. (3) Of 364 cases in which pathology was found at operation, only 164 or 45.1% were diagnosed correctly. These included gallstones also. (4) 38.4% of all the cases in which gallstones were found at operation had been diagnosed correctly with the roentgen examination.

A statistical study of the pathology found indicated that an affirmative diagnosis could be made in 52.9% of the cases showing mild or extreme grades of disease, while a negative diagnosis was made in 44.6% of the same cases. The fact that the truly normal gall-bladder is so rare in adults throws some doubt on the roentgen findings as being truly indicative of clinical disease. The authors question the value of the roentgen examination if only 50% of the cases can be diagnosed.

It is pertinent to note in this connection that the use of a more elaborate technic might give a higher percentage of correct diagnoses. It would be of considerable value to know in what percentage of cases the diagnosis was made roentgenologically when the clinical diagnosis was wrong or obscure.

LEO G. RIGLER.

SPONDYLOLISTHESIS A COMMON LUMBOSACRAL LESION: Bowman (*Amer. Jour. of Roent.*, March, 1924).

Spondylolisthesis refers to anterior subluxation of the body of the 5th lumbar vertebra on the sacrum. Numerous etiological factors have been presented but injury is probably the most common cause. The author presents six cases with roentgenograms which clearly show this condition. In five of these injury was the cause. The condition is probably more common than is generally supposed and the failure to recognize it is due to lack of care in obtaining lateral views of the lumbo-sacral joint. In order to obtain good detail he advises one plate to be taken in the lateral position, using a small cone, the central ray being directed through the joint. All cases of injury to the back or of

lumbar pain should be x-rayed in this manner and dislocation of the lumbo-sacral joint will no doubt be found in a large percentage of cases.

LEO G. RICLER.

A ROENTGENOLOGIC STUDY OF BENIGN TUMORS OF THE STOMACH—Moore (Am. Jour. Roent., January, 1924): A report of 23 cases of benign tumors found at operation which had been studied roentgenologically is presented, together with illustrations. Most of the tumors were found at the pyloric end of the stomach and on the anterior and posterior walls. Over half showed superficial ulceration. The clinical syndrome is very indefinite.

The author reviews the roentgenologic findings in these cases from which he has formulated the following signs:

1. A filling defect, well circumscribed and punched out, is found.
2. The defect is usually on the gastric walls, rather than on the curvatures.
3. The rugæ around the tumor are more normal than found in other conditions.
4. Peristalsis is little disturbed, retention is uncommon.
5. No niche, incisura, or spasm are present.
6. The mass is rarely large enough to palpate.

The most essential feature of the examination is deep and thorough palpation to approximate the gastric walls. Differentiation must be made from: 1. Medullary carcinoma, by the irregularity of the defect, involvement of the curvatures rather than the walls, and presence of a palpable mass; 2. Crater of an ulcerated cancer, which gives a denser meniscus shadow; 3. Scirrhus carcinoma and lues, which give a diffuse involvement, narrowed lumen, and absence of peristalsis. It is almost impossible to distinguish annular carcinoma or saddle ulcer, while prolapse of a pyloric tumor into the duodenum may give the appearance of a duodenal ulcer. Gastric polyposis gives a characteristic mottled appearance which must not be confused with the appearance of food remnants. The differentiation from malignant tumors cannot be absolute, but the attempt should be made.

LEO G. RICLER.

TUBERCULOUS LOBAR PNEUMONIA (PNEUMONIC CASEOUS TUBERCULOSIS)—Sante (Am. Jour. Roent., January, 1924): In the past four years the author has seen 13 cases of lobar pneumonia with a protracted course, which eventually proved to be tuberculous. Clinically, the essential difference from a true lobar pneumonia lies in the mildness of the symptoms, the defervescence by lysis, and the failure to resolve. Practically all the cases occurred in the upper lobes. The sputum may show tubercle bacilli.

Roentgenologically, the cases resemble the ordinary lobar pneumonia very closely. In 2 cases the progress of the process was followed from its inception and in these showed the first consolidation at the hilus, then extension into the lower portion of the upper lobe, finally complete involvement of the lobe. Most of the cases show other

evidence of tuberculosis in the lungs. Resolution may not occur for months. After resolution, cavities were found in all but one case. These are multiple, well defined, and may become fibrosed.

Pathologically, this is an exudative type of tuberculosis. It is possible that much of the shadow found in the plates is due to ordinary inflammatory process. Since the advent of the roentgen ray the number of cases discovered has been greatly increased, so that the condition is not as rare as it was thought to be. The author believes that many of the dense shadows seen in pulmonary tuberculosis may be simple inflammatory processes, rather than an advancement of the tuberculous process. Well-reproduced plates of the cases are shown.

BOOK REVIEWS

BOOKS RECEIVED FOR REVIEW

GENITOURINARY DISEASES AND SYPHILIS. Henry H. Morton, M.D., F.A.C.S., Professor of Genitourinary Diseases and Syphilis, Long Island College Hospital, Genitourinary Surgeon to the Long Island College Hospital and Polhemus Memorial Clinic, etc. Fifth edition, revised and enlarged. 328 illus. 38 full page colored plates. 712 pages. New York: Physicians and Surgeons Book Co., 1924. Cloth, \$10.00.

MEDICAL SANITARY INSPECTION OF SCHOOLS. S. W. Newmayer, A.B., M.D., formerly Chief of Division of Child Hygiene; Assistant Chief Medical Inspector, Bureau of Health; Supervisor of School Medical Inspection, Philadelphia. 79 engravings. 6 full page plates. Philadelphia and New York: Lea & Febiger, 1924. Cloth, \$4.00.

MODERN UROLOGY. Hugh Cabot, M.D., C.M.G., F.A.C.S., Dean and Professor of Surgery in Michigan Medical School, Ann Arbor. Vol. I. 828 pages. 398 engravings. 11 plates. Vol. II. 744 pages. 288 engravings. 8 plates. Philadelphia and New York: Lea & Febiger, 1924. Price of both volumes, \$18.00.

NEW AND NON-OFFICIAL REMEDIES, 1924, containing descriptions of articles which stand accepted by the Council on Pharmacy and Chemistry of the American Medical Association on Jan. 1, 1923. Cloth; pp. 422+XXXIX. Price, postpaid, \$1.50. Chicago: American Medical Association, 1924.

Every physician is continually bombarded with literature, scientific and otherwise, concerning the newer remedies. He has neither the time nor the opportunity to investigate all even of the more promising preparations, and obviously he cannot try them upon his patients without investigation. He must know the composition of the article, must know that the claims under which it is marketed are true; in other words, he must have some critical statement of the actions, uses and dosage as well as of the chemical and physical nature of the product.

This need of the physician is met in New and Non-official

Remedies, which is the official publication through which the Council on Pharmacy and Chemistry annually presents to the American medical profession disinterested, critical information about the proprietary preparations which the Council deems worthy of recognition. In addition to the description of these proprietary preparations, the book treats those non-official remedies which, in the opinion of the Council, are worthy of consideration.

As the book is designed for ready reference, each preparation is classified, and each classification is preceded by a general and critical discussion of that group. These articles are written by those who may speak with authority on the separate subjects, and are a compilation of the best accepted opinions of today. Thus there is a general article on lactic acid-producing organisms in which the newly accepted *Bacillus acidophilus* preparations are discussed in connection with other accepted sour or fermented milk preparations. The animal organ preparations, the biologic preparations, the arsenic preparations, and so on, are discussed in such a manner as to make the accepted facts concerning each group readily available.

A glance at the preface of the new volume will show that the book has been extensively revised. In fact, each new edition of New and Non-official Remedies is essentially a newly written book, fully indexed.

Physicians who wish to know why a given proprietary is not described in New and Non-official Remedies will find the References to Proprietary and Unofficial Articles not found in N. N. R. of much value. In this chapter (in the back of the book), there are references to published articles dealing with preparations which have not been accepted.

New and Non-official Remedies is a book that a physician who prescribes drugs cannot afford to be without. The book contains information about medicinal products which cannot be found in any other publication.

The book will be sent postpaid by the American Medical Association, 535 North Dearborn Street, Chicago, on receipt of \$1.50.

ANNUAL REPRINT OF THE REPORTS OF THE COUNCIL ON PHARMACY AND CHEMISTRY OF THE AMERICAN MEDICAL ASSOCIATION FOR 1923. Cloth; 72 pp. Price, postpaid, \$1.00. Chicago: American Medical Association, 1923.

This volume contains the unabridged Council reports that have been adopted and authorized for publication during 1923. Some of the reports, due to their technicality, have only been abstracted in *The Journal*; others have been published in entirety, and still others have never been published elsewhere.

In this volume the Council sets forth the reasons that certain proprietary remedies were found unacceptable for New and Non-official Remedies, the reason why it has been deemed wise to omit certain hitherto accepted articles from the present, 1924, edition, of New and Non-official Remedies, and the volume also contains certain preliminary reports on products that have therapeutic promise, but are as yet in the experimental stage. There is a long report on the widely advertised Fleischmann's Yeast, which was not found acceptable. Benetol, another article that has had much mention in the daily press, receives attention. There are reports on apiol and mercurial oil, which have been omitted from New and Non-official Remedies. In addition to these types, there are preliminary reports on bismuth in the treatment of syphilis, ethylene as an anesthetic, peptone in the treatment of migraine, and tryparsamid; and there are reports of such general interest as that on intravenous therapy and that on progress and conservatism in therapeutics.

For one who wishes to be cognizant not only of what the Council has done, but why it has done it, the book will be very valuable, for it supplements New and Non-official Remedies with a more detailed account of the activities of the Council during 1923. New and Non-official Remedies records those proprietary remedies which have been accepted; Council Reports treats those which have been found unacceptable, and those which give promise of becoming valuable.

WANTED—Partner or assistant. Large general practice, Minnesota town 800. Territory extensive. Work for two men. Community German Catholic. Hospital next town. Will sell half interest in equipment and business or arrange percentage basis. Young German Catholic with some surgical ability preferred. Only Class A graduate with hospital experience considered. Give age, nationality, religion and references. Address B91, care MINNESOTA MEDICINE.

FOR SALE—Long established practice in town of 2,500. Prosperous community, sixty miles from cities. A snap worth investigating. Specializing. Address B-93, care MINNESOTA MEDICINE.

FOR SALE—General practice in St. Paul of physician recently deceased. Also complete office equipment. Any reasonable terms. Address B90, care MINNESOTA MEDICINE.

GOOD LOCATION—Dentist and physician, corner Thomas and Hamline Ave., Saint Paul, above drug store. Inquire at 1344 Thomas Ave. Telephone: Midway 5467.

FOR SALE—Complete equipment of twelve-bed hospital, including beds, linen, office and operating room furniture, enamelware and rubber goods, dishes, trays, silver and glassware, also wheel chair, bassinets, and various room furniture. In excellent condition. Used only six months. Price very reasonable. Address P. O. Box 135, Elk River, Minnesota.

FOR SALE—Static machine, twelve-plate, in quartered oak, good condition. Does good fluoroscopic work on the extremities. Price \$35.00. Compressed air tank with pressure gauge, good condition, \$5.00. Two x-ray tubes, 6 inches by 8 inches, any fair offer. Leaving state. Address B88, care MINNESOTA MEDICINE.

FOR SALE—Office fixtures and instruments of physician recently deceased. Good opening for practice in southern Minnesota town, 2,000. Address B89, care MINNESOTA MEDICINE.

GOOD OPENING for general country practice at Kindred, North Dakota. For information address B-92, care MINNESOTA MEDICINE.

PRESIDENTIAL ADDRESS: OBSTETRICAL RESULTS*

F. P. STRATHERN, M.D.
St. Peter, Minn.

LADIES AND GENTLEMEN:

You have honored me beyond my merit with the highest office in this association, and for the past year and a half it has been my humble pleasure to serve to my utmost ability your best interests in promoting the ideals and traditions of the Southern Minnesota Medical Association. This organization has no axes to grind but is wholly interested in bringing together, once a year, all members of the association and their friends, regardless of geographic boundaries. Primarily, its object is to increase knowledge and skill in the healing art, to build up a more ethical and tolerant profession and emphasize, most of all, the needs of the general practitioner.

I wish to quote Dr. Hugh J. Means, speaking before the Columbus (Ohio) Academy of Medicine, voicing a thought that is now quite firmly entrenched in the minds of practitioners all over the country, when he said: "The cults always have been, are and always will be with us. Too much effort is expended in attempting to suppress the fact of the day and not enough in searching for the true cause that enables it to exist. Physicians, as a whole, pay too little attention to the psychology of medical practice and consider medicine as an exact science, forgetting that the patient is an individual with prejudices, idiosyncrasies and temperaments. A keen analytical mind in ordinary affairs will function in an absurdly illogical manner in health matters. When a patient consults a physician, his mind is made up in advance that there is something wrong. When told that his illness is merely a state of mind or something of small mo-

ment, he may appear satisfied; but deep in his heart he is disappointed. We all rather enjoy the opportunity to excite a little sympathy for ourselves and after recovery like to think that our illness was a little more severe than ordinary. The patient wants something done to him. The less serious his condition, the more the process is enjoyed; not being satisfied merely with advice, which to his unscientific mind is more or less intangible, the patient drifts to a healer. It may be generally admitted that physicians themselves are responsible to a large degree for the drift to cults of persons who complain of being ill, when no definite pathology is present, because of a disposition to dismiss the patient with the admonition that "there is nothing wrong."

Let us say that one-third of the patients who consult a physician are scarcely in need of medical attention, as far as real demonstrable ailments are concerned. These patients are entitled to careful, thorough examination and attention and not the usual cursory hurried examination with a little indefinite advice regarding habits and possibly a few recommendations as to eating and exercise. Thus, patients pass from one physician to another and, receiving the same attention and advice, gradually become more and more dissatisfied. This is the main reason for quack cults, practices and all manner of irregulars. If a patient leaves the office unsatisfied, it is usually the fault of the physician. We have never heard of a patient consulting an irregular and being dismissed without the recommendation of a complete course of treatment and it would be difficult to estimate how many millions of dollars fall into the hands of the unqualified, the unscrupulous and the rank unethical.

This problem is worthy of the most serious consideration. How are we to treat these patients? There can be but one answer. We must give this type of patient the time and serious attention he deserves or he will continue to encourage and patronize the ignorant and unqualified. Hygienic instruction and sensible advice are all available and distinctly helpful, but the average patient is not

*Read before the annual meeting of the Southern Minnesota Medical Association, Mankato, May, 1924.

satisfied with this. He or she, especially she, wants some kind of active treatment upon which hope and confidence can be based. Because these patients will probably recover without active treatment is no good reason for relying entirely upon the unaided forces of nature. Many of them will be satisfied with this and will need no further attention; others will require helpful direction and re-education, even medication, though its effect is more mental than physical in character.

In order to combat the cultist, the practitioner will find it to his advantage to at least know on what his practice is founded. He will find, very likely, that regular medicine can give every real advantage offered by the special cult and more. The patient can be advised by his physician as to diet, water intake, exercise, relaxation and even as to attitude of mind. "The doctor of today has greatly neglected his psychology and has given to the mental healer an unusual opportunity," says Dr. Hubbard of the New York Board of Health. "If the physician does not intellectually respect the complex matters of the soul and their interdependence," to quote the late Dr. Wier Mitchell of Philadelphia, "he is unfit for higher seats in the temple of healing. Through closely studying and appraising his enemy, the unqualified practitioner, and especially keeping in touch with the latest developments in both medical and mental science, the physician of the legally recognized schools can successfully cope with the menace of the cults."

Great advancement in medicine during the past twenty-five years has been accomplished and a few of the more important discoveries may be briefly mentioned.

Major Walter Reed and James Carroll in 1899 proved the cause of yellow fever to be either an ultramicroscopic organism or a filterable virus transmitted to man by a particular species of mosquito, the *stegomyia fasciata*.

A quarter of a century ago, our teachers talked of the etiology of lues. The *spirocheta pallida* was unknown. In May, 1905, Fritz Schandinn, working with Erick Hoffmann, crowned his life work by the discovery of *spirocheta pallida*. This was the first step in the conquest of syphilis. The next was the biochemical discovery in 1910 by Paul Ehrlich of Strehlen, Silesia, of salvarsan, and his work enabled August von Wassermann in 1916 to hit upon the specific and extremely reliable diagnostic test for syphilis.

One of the greatest medical achievements in the World War was the conquest of wound infection, through the introduction in 1915 by Carrel and Dakin of a physico-chemical principle of wound irrigation by a gas in solution.

A student senior of the University of Minnesota in 1899 was asked in a quiz class of the late Dr. Alexander Stone how he would diagnose a stone in the ureter. To the consternation and amusement of the class, he replied: "I would pass a probe into the ureter." The professor replied: "Young man, you will be dead and resurrected a thousand years before you will ever pass a probe into the ureter"; but the introduction of the cystoscope by Max Nitze in 1916 vastly improved the surgery of the bladder and ureter.

The discovery of insulin by Banting and Best marks an epoch in the treatment of diabetes, the previous treatment of which had been so unsuccessful and discouraging. This remedy will prove invaluable in prolonging and saving valuable lives. In time I hope there will come a demand for a course of instruction in our public schools in dietetics which might serve to check the apparent increase in this prevalent disease.

One of the reasons why physicians in general have failed to hold or to satisfy their patients is the fact that no record is kept of their cases; were this done and case records reviewed and studied it would prevent repetition of mistakes in diagnosis and treatment and aid in cleaning up the cult problem. This, of course, takes time, but it pays to do it.

Our records of obstetrical patients, kept for twenty-five years in a country and city practice which totaled 1,032 cases, very few of whom were hospitalized, serve as an illustration. The anesthetic was chloroform; gas or ether was used in a few cases. No untoward effects were observed and I would say that chloroform, intelligently and properly administered, is a very satisfactory anesthetic in obstetrical work. Gas tanks are too cumbersome to carry and its administration is impractical in that assistants are, as a rule, few and untrained and the physician must perform the added duty of nurse and anesthetist. When the labor pains are sufficient to insure continuance, the anesthetic is administered in amount to relieve the sharp edge of the pain. At the completion of the second stage, the anesthetic is pushed to primary

anesthesia and seldom, if ever, do I have a case of nausea or vomiting following delivery.

As to abnormal presentations and complications of pregnancy, we note the following:

Post partum hemorrhage.—Fourteen cases in number. Most of these cases were controlled by the usual measures such as kneading the uterus and the administration of ergot and pituitrin; but a few cases required a pack for several hours. Holding and firmly manipulating the fundus usually will prevent and control hemorrhage, except in uterine inertia or laceration of cervical vessels.

Contracted pelvis.—Ten cases. Seven of these, all in the same mother, were very difficult, required forceps, and resulted in the loss of three of her infants from pressure and asphyxiation. The last and most difficult of all, was a breech presentation. Failing in external version, the aftercoming head was finally delivered with forceps. The eighth case, a primipara seen too late to remove to a hospital, was delivered, with the assistance of two other physicians, by forceps, resulting in the child's death due to pressure and asphyxiation. The mother was advised in the future, should the occasion arise, to go to a hospital for cesarian section. This she failed to do and, in the hands of another physician, delivery resulted fatally to the child. Her third delivery, an operation at Rochester, resulted favorably to mother and child. This demonstrates the importance of careful repeated examinations and watchfulness to detect complications in advance, so as to be prepared for any emergency. The ninth case of contracted pelvis was in a primipara, upon whom a cesarian section was performed successfully. The mother, a minor, lived to appear in court as a witness against her seducer, who was duly sentenced to serve a term in the State Penitentiary.

Adherent placenta.—Seven cases. All required manual removal, but with uneventful recovery.

Twins.—Seventeen cases with two infantile deaths. One case of triplets was ushered into the world. The diagnosis was twins. The first infant, a female, weighed three pounds and was born 4:15 a. m. This satisfied the fond father, who had previously notified me that future calls would not be forthcoming if the prospective was not a girl. But complications arose and the second child, a female, weight three and one-half pounds, was born at 5 a. m. The third child, a female, weight two and one-half pounds, was born at 5:10 a. m. This was more than the father had figured on and I assured him that he was abundantly supplied with girls, to which he replied: "Well, I did not want three." The mother and children are doing well.

Breech presentations.—Thirty cases. Two of these cases were high, so that a hook was used around the groin over the thigh, resulting in perforations of the abdominal wall at Poupart's ligament in both cases. The wounds under treatment healed quickly. One case with prolapsed cord was delivered successfully, but another with premature rupture of membrane was very difficult. One must have a fully dilated cervix for delivery of the aftercoming head, the danger being that the aftercoming head will be caught by the insufficiently dilated cervix and unless the child is delivered in from five to seven minutes from the time of the appearance of the cord at the vulva, death may result. The extraction of the aftercoming head in this case required

forceps, the resulting trauma and traction causing its death the following day.

Stillbirths.—Twenty-eight cases. A version was performed in one case of malposition, but on account of the extreme size of the aftercoming head, craniotomy was necessary. Of the remaining, one was a monstrosity; one, a dry labor breech presentation; four, contracted pelvis; one, strangulation by the cord before my arrival; one, strangulation with loops of cord in forceps; and the rest to causes such as prematurity, lues and asphyxiation by prolonged labor.

Dry labors.—Thirty-four cases. Rupture of membranes prematurely ranging from a few hours to seven days.

Version.—Six cases. One for pendulous abdomen and non-engagement of head; one, placenta marginalis; one, placenta abruptio; and the rest for causes already mentioned.

Eclampsia.—Three cases. One, postpartum, made a good recovery; one, antepartum and postpartum with recovery of mother and child; and one in which albuminuric retinitis forced induction of labor at eight months, with uneventful recovery.

Posterior positions.—Nine cases with one death from version.

Face presentations.—Nine cases.

Placenta marginalis.—Four cases.

Placenta centralis.—One case, eight months parturition, no fatalities.

Acute appendicitis.—One case. Abscess was drained at hospital, seven days postpartum, with good recovery.

Uremia.—One case, ten days postpartum, with maternal death.

Bartholin gland abscess.—Two cases.

Deformed and crippled cases.—Twelve in number. One, a bifid thumb at the second joint, was operated under local anesthesia while the child slept; one case, absence of left forearm and hand; two cases each with twelve toes and twelve fingers, which supernumeries were amputated at birth with excellent result; club feet, four cases; one infantile hand with web fingers to the second joints.

Spina bifida.—Three cases. One, located in the cervical region, was operated in the city about the second month with good recovery; the other two, in the lumbar region, the thin membranous type, became infected, resulting fatally.

Hydrocephalus.—One case, which died.

Two interesting cases should be mentioned: One was a child with cranial tabes; rectal palpation gave the impression of a breech presentation; delivery was slow on account of sluggish uterine contractions. The soft head presented a large hernia of the vertex, which was due to the absence of bony structure of parts of the parietal and temporal bones. Strange to say, this filled in with bony growth in a few months. The other case, of lesser involvement about the posterior fontanelle, looked like an ordinary caput succedentium, but was really a hernia of the brain, 7.5 to 10 cm. in diameter. This gradually disappeared with complete ossification in three months.

Ectopic gestation.—Two cases. One was sent to the hospital with recovery from operation and one died before she could be taken to the hospital. This was about twenty-five

years ago. With modern good roads and auto ambulance, we most likely could have saved her.

Two mothers died of pulmonary tuberculosis shortly after childbirth and one with influenza died suddenly in the second stage of labor.

Forceps cases.—One hundred and sixteen. The large majority were normal cases in which advance was delayed in the parturient canal or a long or dry labor threatened to exhaust the mother, endanger the child by asphyxiation or give rise to hemorrhage from uterine inertia. Forceps are a very great help when indicated, but one should always study the indications carefully and wisely before applying them, as the normal delivery is the safest to mother and child. How many times have we thought we would need forceps and have had them boiling to find that the child was born before we could use them.

Pituitrin is a valuable aid only where wisely used. With an undilated cervix or a posterior high position, to give pituitrin invites disaster. These cases are best treated by correcting the posterior position, or ironing out the rigidos with the sterile gloved fingers, by performing a version or applying forceps. In this way a ruptured uterus or a dead child will be averted.

The late Dr. Merritt, a most excellent obstetrician, informed me that he had never applied forceps to a living child without bringing it alive into this world. This requires great skill, experience and good judgment, and one should well strive to attain this proficiency.

INSULIN AND KETOSIS

Ketosis is not confined solely to cases of diabetes. It is an accompaniment of carbohydrate starvation, however produced. Acidosis is not infrequently found in preoperative or postoperative conditions, owing to enforced deprivation of food for one reason or another. It is found accompanying so-called toxic vomiting, sometimes particularly in the persistent type seen in pregnancy. Attention has been called to the use of insulin in the treatment of nondiabetic acidosis. The alleviation of this condition through the administration of glucose by rectum or parenterally has been demonstrated. More prompt success has been reported through the combined use of insulin hypodermically and glucose intravenously. While the treatment gives promise, it is not free from danger. Insulin therapy demands care in the case of a diabetic patient. Doubly great is the need of intelligent precaution with the nondiabetic patient.—*Jour. A. M. A., May 24, 1924, p. 1695.*

RADIUM AND RADIUM EMANATION

Radium is commonly supplied in the form of radium salts enclosed in containers. Also, tubes containing radium emanation are available. Salts of radium disintegrate at a rate so that 1,780 years elapse before the compound loses one-half of the initial activity. On the other hand, radium emanation loses about 0.75 per cent of its activity each hour, and consequently its activity is practically gone after one month.—*Jour. A. M. A., May 3, 1924, p. 1462.*

RECONSTRUCTIVE SURGERY AND REHABILITATION—THEIR RELATION TO SURGERY OF TRAUMA*

HARRY E. MOCK, M.D., F.A.C.S.

Chicago

In the field of general surgery and in the special fields of orthopedic and plastic surgery are found many deforming conditions which, uncorrected, handicap the individuals, rendering them unfit to compete in employment and to enjoy the usual pursuits of the average able-bodied man. During the war many old methods were revived and new ones invented which aimed at the prevention or correction of physical deformities. This work was classified as physical reconstruction and the necessary surgery used to overcome the disability was called Reconstructive Surgery. This type of surgery combines with the necessary surgical procedures such adjuncts as physiotherapy, occupational therapy, retraining exercises, and a continuous follow-up or supervision of the case, by the surgeon, until as complete a functional restoration as possible is obtained.

Many of these handicapped individuals are so badly disabled that function cannot be restored to the point of permitting return to their old occupation, therefore, hand in hand with the developments in medicine and surgery resulting in consideration of reconstructive measures, has been born an economic development known as Rehabilitation of the Disabled. Rehabilitation deals with those measures necessary to make a disabled individual fit to resume his economic position in society. Rehabilitation of the disabled embodies five logical steps, often overlapping in function, but all aiming at the final economic end-result, independency.

These steps are:

1. Physical and mental restoration, by adequate and completed medical, surgical and hospital care;
2. Convalescence, under environment which tends to retrain work habits, to harden and strengthen the individual rather than under environment which tends to hospitalize, parasitize and make possible the development of functional neuroses;

*Presented before St. Paul Clinic Week, St. Paul, January, 1924.

3. Retraining, when necessary, for a new occupation, or an occupation allied to his old work—called vocational training;
4. Replacement at suitable employment;
5. Continued medical and economic supervision to see that his rehabilitation is completed and so remains.

Prior to the war examples of rehabilitating the disabled were found chiefly in the work of the medical departments of a few great industries. The return of their permanently disabled employees, following work accidents, to new types of occupations which they could carry on and which usually had some incentive for advancement; the selected occupations for their cardiac cases; the treatment in sanatoria of their tuberculous employees and, when the disease was arrested, their return to selected, suitable occupations in the plant, all furnish excellent examples of the meaning of rehabilitation. Unfortunately only a very small percentage of the total disabled population of the nation was included in this number. Nevertheless this pioneer work paved the way for this new medico-economic movement.

During the war the medical department of the army developed great plans for the Physical Reconstruction and Rehabilitation of the Disabled Soldiers. Suffice it to say that prior to the wholesale discharge of these disabled soldiers following the armistice, this work of salvaging these men was progressing exceedingly well. It was during these months that the foundation was laid for the present scope of the rehabilitation movement. Time and again it was pointed out that the casualties from the great industrial army in this country were annually more than three times as great as the casualties in our military army for the entire war. Yet no national movement for the reclaiming of these disabled civilians had ever been launched.

As a result of this propaganda New Jersey in 1919 passed the first state law for the Vocational Rehabilitation of the Disabled from Industry. Since then thirty-five other states and the Federal government have passed similar laws—some of them broad enough to include the disabled from disease, accident or congenital deformity. These laws all provide for the vocational training of these disabled, the furnishing of artificial appliances when necessary and the replacement at suitable employment; the funds for this service being furnished by equal appropriations from the state and federal

governments. Five of the states function without federal aid. The laws are broad enough to include physical restoration, and are so interpreted in a few states, for they read: "To render a disabled person *fit* for remunerative employment."

All working in this field now realize that a great many of the cases can be improved physically, and must be so improved, before their vocational training and their economic rehabilitation can be assured. Thus reconstructive surgery, or medical reconstruction, is often the connecting link between the disabled and his future remunerative occupation.

Estimates differ as to the number of disabled in each state entitled to the benefits of the rehabilitation act. Thus, in Illinois, one group has reported that approximately 1,000 persons annually will be found needing this service, while another group claims that over 100,000 permanently disabled men and women can be found coming under the act. Remember that the total number of disabled now in our midst are being added to annually by the increasing number of industrial, automobile and public utility accidents. Statistics quoted by me* showed that annually 875,000 people were disabled for more than four weeks by industrial accidents alone; that 76,000 suffered loss of members; that 200,000 were otherwise permanently disabled and that 28,000 of our people were killed in industry. Statistics quoted by other writers since then show even a higher casualty list. This does not include the thousands who are disabled on our streets, in the homes, on the farms; neither does it include the disabled from occupational diseases, the cardiacs, the tuberculous, the paralytics, the mental defectives and others disabled by disease and congenital defects. All of these cases, if above the working age, are entitled to rehabilitation by the states having such laws. The great majority require some form of physical reconstruction to *fit* them for remunerative occupation. These facts give one some conception of the size of the medical and surgical problem involved.

Every paper or address should have some real motive for its publication or delivery. Lest you miss the objects of this paper, I want to insert here the two points I am endeavoring to drive home:

1. To increase the knowledge of our profession concerning these rehabilitation laws, and the im-

*Reconstructive Surgery, Minnesota Medicine, June, 1921.

portance of every physician referring his permanently disabled patients to the proper authorities so that they may receive this great opportunity of economic independence.

2. To urge the early application of reconstructive measures to every serious injury case, with the view of preventing permanent disabilities as far as possible, and of preventing traumatic neuroses and habits of idleness and dependency which frequently are more disabling than real deformities.

It is surprising how few of our surgeons, and our hospitals, have any real knowledge concerning rehabilitation or the fact that their permanently disabled patients can be referred to the state rehabilitation commission for retraining and placement at useful occupations. They are so in the habit of thinking only of treating the injury until healing has occurred that their minds do not function beyond that stage into the field of the patient's future usefulness. Or, if they do look into his future it is only with a sense of sorrow and pity for another victim of accident or disease.

Recently I witnessed the amputation of a leg by one of our best surgeons. The patient was a comparatively young man, a laborer, with a family. The surgeon said: "Poor fellow, he won't be able to go back to his usual work; he knows no other work; I wonder what will become of him and his family." This surgeon was surprised and gratified to learn that his patient could be referred to a state department where an artificial leg would be furnished him and where he might be trained for a new job.

In this case the amputation was done because of a disease not related in any way to his work; therefore, this patient was without employee's compensation. In our city, the charities or some other philanthropic organization can be found, which would finance this family during the period of the father's retraining for a new job. As yet the state law does not provide for maintenance during the period of training, and it is questionable whether this is advisable. The majority of these cases, however, can be trained for new work in some industry where they will receive some wage during training. In our community, workshops exist and others are being provided where the more serious cases can receive training and at the same time be paid wages, the money for this being obtained by the sale of fabricated articles plus one-half the weekly sum the charities would otherwise have to provide for

the maintenance of this family. The sum from the charities is paid direct to the workshop management rather than to the individual—the latter is thus unaware of the fact that he is receiving aid.

The following case which I have had under my care for the past two years illustrates how many of these cases may be handled:

F. K., aged 34, married, two children, lived in a small rented flat, employed as a fireman and engineer in a large office building. In February, 1922, an elevator which he was operating fell seven stories. Patient was brought direct to my service at St. Luke's Hospital suffering from backward dislocation of right knee, lateral dislocation of right patella, fracture and complete outward rotation of external condyle, fracture and complete displacement of internal condyle into knee joint cavity.

Treatment consisted of immobilization and traction in a Thomas splint with fomentations to joint for one week; reduction of dislocation under gas anesthesia with continued immobilization and traction in Thomas splint; operation two weeks later on external condyle, gas anesthesia, consisting of replacement of fragment and fastening of same to shaft of femur by ivory peg (I now use beef bone pegs); one week later, operation on internal condyle, gas anesthesia, replacing fragment in normal position as nearly as possible and holding same in position by drilling two holes each through shaft and fragment, threading kangaroo gut through these and tying in place.

This last operation was indicated because this internal condyle lay in such a position that weight bearing would be between the head of the tibia and this pointed fragment with ankylosis of knee bound to result.

This last operative wound became infected—*staphylococcus albus*. Bone developed in the capsule and tendons about the joint and even in the muscles—a condition similar to myositis ossificans. Two subsequent operations for drainage and removal of necrotic bone were necessary. A small discharging sinus has persisted in this case but is gradually healing.

Ordinarily this patient would be continued on weekly compensation of \$16.00 per week by the industrial commission until this wound had completely healed and then a settlement would be arranged based on the percentage of total disability. The healing of this wound may take two or three years. By the end of that time this patient would

be a confirmed loafer and pensioner. Too often have I seen the pitiful mental attitude of these long drawn out chronic cases.

During this patient's stay in the hospital he was given various forms of occupational therapy. Soon it developed that he had a natural inclination toward mechanics. This was fostered by talks with the patient, and by his reading, and ward occupations having a vocational trend. One year ago, when it was felt that patient could go about, returning twice or three times a week for dressings, the following arrangement was made:

The insurance company settled with patient for a loss of 25 per cent of his leg. Settlement at this time on existing condition would have been a 50 per cent loss, but I assured patient and the insurance company that this loss would be decreased one-half by time and further treatment. Patient also had eighteen months from time of this settlement to re-open case if my predictions of improvement failed. The insurance company guaranteed all further surgical care needed. This particular insurance company has grasped the ideals of rehabilitation.

Patient was then referred by me to the representative of the state rehabilitation commission with my recommendations for training in a practical course of mechanical engineering. This was arranged and patient was sent to the Armour Institute. After a short time he was given a part time job in the engineering department at Armour's plant and the remainder of the day was spent at the Institute. At present he is continuing his studies by practical full time employment at Armour's. Recently he was transferred to the draughting department. He received wages from the time he started at part time employment. At present he receives \$34.00 per week although he is still in training. The lump sum settlement he received from the insurance company was used as a part payment on a duplex apartment. Patient and his family live in one apartment and rent the other. He is keeping up his payments and making money in addition on his rent savings.

Recently this patient told me that his accident was a lucky thing for him. Before it occurred he was a satisfied laborer but now he is learning a good trade, owns his home and is making more money than he ever made before. This is the ideal of compensation expressed in terms of rehabilitation—not merely a pension over an indefinite

period, but a future compensation for the injuries sustained expressed in terms of a happier, more contented, more productive member of society.

Turning now to the second point in this paper, namely the application of reconstructive methods to all traumatic cases with a view of preventing or diminishing permanent deformities, traumatic neuroses and habits of idleness and dependency.

Recently a representative of a large casualty insurance company approached me with the proposition of doing their reconstructive surgery on their bad results from industrial surgery. My reply was that if they would do good reconstructive surgery from the beginning of the injury they would have fewer bad results and less need for a surgeon to do corrective work after the damage was done. Gradually most of our representative casualty companies are learning the lesson that the more expensive surgery in the first place is the cheapest in the long run.

During the last year there have been referred to me for reconstructive cure, that is, restoration of function, eight fractures in or near the shoulder joint, twenty-one cases of periarticular shoulder injuries, of from one month to three years' standing, including subdeltoid and subacromial bursitis, traumatic arthritis or periarthrititis, tearing off of the greater tuberosity, tendosynovitis of the long head of the biceps, et cetera, a constricting scar and an abscess of the shoulder joint.

In practically every one of these cases a careful review or backward look revealed the time or place when certain reconstructive methods if properly applied would have prevented or greatly reduced these permanent disabilities. The early and frequent use of the x-ray; the application of splints or traction in such a way as to prevent the stiff joints or the useless arm hanging at the side; the early use of physiotherapy; the developing of work habits early rather than waiting until months of hospital care was completed, are all methods of reconstruction which should have been applied as continuous treatment from the onset of the injuries instead of waiting until months later when the cases were referred for reconstructive surgery.

Reconstructive methods involve not only the proper diagnosis and proper early treatment of the injury, but certain adjuncts, properly applied, looking toward the early restoration of function and the redevelopment of work habits. This last point is very important in industrial accident cases be-

cause the weekly compensation plus the desire for a lump sum settlement for permanent disability, a desire frequently abetted by legal counsel, tends to keep many cases away from work for months or years.

These adjuncts are occupational therapy, physiotherapy, personal supervision of the application of these methods by the surgeon and stimulation of the patient to try active motion and effort on his own part. Again let me repeat that most of these methods can start within a few days after the accident instead of waiting until the permanent disability is more or less fixed before starting reconstruction. Therefore, reconstructive surgery is not limited to chronic diseases and deformities.

Occupational therapy is either diversional or purposeful. It consists of work of some type given to the bed patient (bedside occupation), to the patient able to sit up and go about the hospital (hospital work—shop occupations), and to the ambulatory case (either returning to the workshop at the hospital or to workshops established away from the hospital).

Diversional occupations serve chiefly in preventing the patient dwelling on his troubles, to make him more satisfied with his hospital sojourn and to reawaken an interest in his daily contact with life.

The surliest, most grumpish patient, complaining of the carelessness of his employer for allowing such an accident, complaining of the food and surroundings at the hospital, discontent with the treatment given, can often be changed into a contented, co-operative patient by persuading him to make a scarf for his wife on one of the little bedside looms utilized for this purpose. Work furnished one patient is often contagious and soon all the men in a ward will be doing some type of work. Before Christmas several of our men patients at St. Luke's Hospital were very busy making scarfs, selling them to the nurses and doctors for from \$2.00 to \$5.00 each.

Purposeful occupational therapy is the prescribing of some work which will tend to restore function in a member, as the use of a plane, a hammer, a saw or a gig-saw to teach the patient to grasp with or use stiff fingers, to loosen up a stiff ankle joint, et cetera. Another type of purposeful work is that which has a vocational trend, preparing the patient to take up vocational training for a new

occupation when his injury will prevent return to his old job.

The best type of occupational therapy, and the one hardest to sell to employers and to insurance companies, is to return the injured patient as soon as possible to light occupation in the plant or industry where he was formerly employed. Many an injured man, previously doing heavy, arduous work, must frequently wait months before his injury is sufficiently recovered to permit return to this heavy work. Such a one, shortly after he becomes an ambulatory case, could return to light work if his employer would co-operate and find a light job for him. It would be worth while for the insurance company to pay the wages of such a patient rather than continue to pay compensation over a period of months or even years. In the latter case this patient develops habits of idleness, becomes a pensioner, thinks constantly of a big settlement that will permit him to loaf the rest of his life or to start up in an easy business for himself and, abetted by his lawyer and family, he unconsciously endeavors to magnify his disability. Thus he becomes a traumatic neurotic case.

My experience prior to 1917, while serving as chief surgeon for a large industry, demonstrated the value of light work in the plant as the greatest form of occupational therapy and also as the best type of vocational training in many cases. Dr. Farnum, chief surgeon for the Avery Company, of Peoria, has for several years returned the majority of his fracture cases to light work within three weeks. Have you ever thought of the infrequency of traumatic neuroses among injured farmers, among business men or small store and shop keepers? These people when injured are forced to get back on the job just as soon as they become ambulatory cases.

This work, occupational therapy, is of great aid in reconstructive surgery and *must be applied early*. This idea must be sold to employers and to insurance companies if malingering and other forms of neuroses are to be reduced.

Physiotherapy, so sadly neglected by our profession prior to the war, enriching the armamentarium of all forms of quackery, has again become a recognized therapeutic agency since the war. Every hospital receiving and treating traumatic cases should have a trained physiotherapy aid to give massage, passive and active motions, hydrotherapy and function restoring exercises to such cases, under the

direction of the surgeon; and the same should be started just as early in the course of treatment as compatible with healing of the injury.

Heat is one of the best therapeutic agents. It can be applied as continuous hot fomentations, by the Burdick electric baker, by diathermy or other forms of electro-therapeutics. Elaborate apparatus is not necessary for the early treatment of injury cases. When the joint has become stiff or a member has been allowed to lose its range of motion, too often the stage reached before cases are referred for physiotherapy, then more elaborate apparatus and more prolonged daily treatments are required.

Physiotherapy misapplied, or too strenuous physiotherapy, can be detrimental to a case, increasing the permanent deformity. Again, unless carefully guarded it can slide over into the realm of quackery. Many surgeons doing chiefly industrial accident work have installed quartz lights, Burdick bakers and other forms of apparatus. Several insurance companies have put in physiotherapy units in connection with their claim departments and have employed doctors and nurses to treat chronic disabling conditions after the surgeon has completed the acute treatment. In many cases good results are obtained but too often recovery is delayed indefinitely. For example:

Recently I saw a man who had not worked for four months because of an injured shoulder. History showed that he had been carrying one end of a heavy plank on his shoulder when it slipped off and he caught it with his hand, thus giving his entire arm and shoulder a severe jerk and jar. He had been treated in the office of a doctor whose work was limited to insurance cases. Every day he went to this office and the nurse put a lamp over his shoulder and baked it for twenty minutes, followed by massage. Complaints on this date of examination were very indefinite and amounted to this: "I can't use it." Examination showed no swelling, variable points of tenderness, complete range of motion, and over the shoulder variable points of alleged anesthesia. The x-ray examination was negative. There was absolutely nothing wrong with the shoulder. He had developed a neurosis, which was gradually passing over into the realm of malingering.

When told that there was nothing wrong with his shoulder and that he could use it, he replied: "There must be something wrong with it or the insurance company wouldn't have paid me all these

weeks and the doctor wouldn't have treated it every day." Thus the daily, easy application of a routine type of physiotherapy had allowed this case to drift into a traumatic neurosis.

Another case, recently seen, sprained his ankle, was sent to the insurance company, ankle strapped and placed under the Burdick lamp for this form of physiotherapy. He reported for daily treatments for three weeks, walking on the foot every day. Because he complained that ankle was becoming more painful, he was referred for treatments. An x-ray was taken before treatments were given, which showed a transverse fracture of the fibula without displacement. These examples and scores of others are convincing evidence that there must be an intelligent surgical sense directing the application of physiotherapy, otherwise it becomes a form of quackery.

Intelligent, carefully directed occupational therapy and physiotherapy after the case has become convalescent and able to be away from the hospital is equally essential for rapid recovery and restoration of function. A good physiotherapy laboratory, directed by a skilled medical man, co-operating with the surgeons who have treated the cases, is the best means of meeting the reconstructive problems during the period between hospital treatment and return to work. Because the surgeons have paid so little attention to this period of treatment, simply telling the patient to have some member of the family massage the part, a great many of these cases have drifted into the hands of the osteopaths and chiropractors. Many of these irregular practitioners have installed physiotherapy appliances and are tending to keep these methods in the field of quackery. Dr. John Coulter, working in his physiotherapy institute in Chicago and in the physiotherapy laboratories at Central Free Dispensary and Cook County Hospital, has well demonstrated that this is a scientific field belonging absolutely to the realm of medicine and surgery.

Out of the great variety of deforming conditions following trauma that have been referred for reconstructive surgery, I have chosen shoulder joint injuries to illustrate the early application of reconstructive methods with a view of preventing deformities.

Of all joint injuries referred to me for treatment, those of the shoulder joint are by far the most common except the aggravating and numerous conditions developing about the lumbar and sacro-iliac

regions. Lovett, Codman, Magnuson and Coulter and the older writers, Von Bergman, Thiem, Dittmar and others, all say in substance, "probably no other joint is so frequently injured and gives such consistent trouble as the shoulder." I would add to this that probably no other joint when injured is so consistently mistreated as the shoulder.

Von Bergman* quotes Dittmar as follows: "Of twenty-eight cases of sprain of the shoulder, only five were cured by an average treatment of 9.4 months; after 13 months in twenty-three cases there was still an average disability of 21.4 per cent." One is startled by the lengths of treatment mentioned, nine and thirteen months, for in this day of employees' compensation and of insurance companies urging rapid recovery, few surgeons persist in such long periods of treatment. Rather they tend to discharge the case before recovery is complete, assigning the lack of full restoration of function to a traumatic neurosis or malingering. One wonders, however, in reading Von Bergman's treatment of shoulder injuries if the lack of that essential factor in treatment, *the immobilization of the arm at a right angle abduction*, did not influence the prolonged period of treatment.

In shoulder joint injuries there are a few essential points in anatomy, diagnosis and treatment which every surgeon treating these cases must constantly bear in mind.

ANATOMICAL POINTS

1. There are twelve muscles passing over and around the shoulder joint and involved in its movements which can be divided into a *Strong Group* and a *Weak Group*.

The *Strong Group*, chief of which are the pectoralis major, the latissimus dorsi, subscapularis, teres major and triceps, form the strong adductors and internal rotators of the arm. The *Weak Group*, chief of which are the deltoid, the supraspinatus, infraspinatus and teres minor, form the less powerful abductors and external rotators of the arm.

2. The arm hangs vertically at the side in the position most naturally assumed by gravity. Overcoming this force of gravity becomes a most important factor when muscles long unused and atrophied, therefore weakened to a still greater extent, must again take up the burden of abducting and elevating the arm.

3. Surrounding this joint are numerous anatomical parts which may be involved in injury and

interfere greatly with joint function. Thus are found numerous bursæ; many tendons, one of which, the long head of the biceps, has a sheath communicating with the joint proper; tuberosities and other bony prominences which may be torn off by direct violence or severe tendinous pull; a scapula which must be fixed for certain joint movements and must be freely movable for others; nerves and blood vessels in the axilla which frequently are involved in injury, and glands in the axilla that make this a common site for infections with resulting scars that may interfere in function.

DIAGNOSTIC POINTS

1. No joint in the body has so many parts intimately related to it as the shoulder joint. Injuries may involve several of these parts; in fact, in severe trauma it is seldom that only one of these parts is involved. Thus, a fall on the outstretched arm or a direct blow to the shoulder may cause a bursitis, a contusion of the joint surfaces and a chipping fracture of the margin of the glenoid fossa. Every part involved in the trauma must be diagnosed and considered.

2. X-rays of the simplest injuries of the shoulder joint are indicated. No dislocation of the shoulder should be reduced without first having an x-ray examination because too often a fracture of the anatomical neck of the humerus simulates perfectly a dislocation; too often a small chipped fracture of the glenoid margin complicates the dislocation or some other bone injury complicates it and means, if unrecognized, a permanently disabled shoulder joint.

If the first x-ray fails to show pathology and yet the symptoms persist, a second x-ray, two or four weeks later, often shows the calcareous deposits in a subdeltoid or subacromial bursitis, a roughening of the head of the humerus or deposits in the joint indicating a traumatic arthritis, or other slowly developing pathology. Time and again a shoulder joint case is referred to me with the statement that the x-ray, taken at time of injury, was negative. The case is usually called a neurosis, and when I take a second x-ray, the real pathological condition is very apparent, to the chagrin of the physician referring the case.

3. Failure to test the nerve sensations about the shoulder joint often accounts for failure to diagnose a nerve injury as the cause of the prolonged disability—as a circumflex nerve injury.

*System of Practical Surgery, Vol. III. H. C. W. B. Co.

4. Persistent pain about the shoulder in the absence of all findings, frequently called neuritis, can often be accounted for by an x-ray of the cervical vertebrae showing an osteoarthritis as the cause.

TREATMENT POINTS

1. The first essential in treating all injuries of the shoulder joint is to protect as far as possible the weaker group of muscles, the abductors and external rotators; and to prevent contraction of the stronger group. This is accomplished by holding the arm at or a little above a right angle abduction and in partial or complete external rotation during the period of complete or partial immobilization. This can be done best by the use of a cast or by means of extension and pulley apparatus with the patient in bed, or in selected cases by some one of the airplane splints, preferably the Crane-Savenay splint.

2. Ninety per cent of the persistent disabilities of the shoulder joint are due to immobilizing the arm at the side of the body in partial or exaggerated adduction position. In young people or in certain dislocations of the shoulder joint, with only a week or ten days' immobilization before use of the arm is allowed, such a fixation may not be disastrous. But in people past middle age adduction fixation for any length of time on account of dislocation, fractured clavicle, fractured humerus or injuries in or about the shoulder joint, is absolutely contraindicated.

Try to raise the arm of an old man who has had it fixed in adduction position continuously for two weeks and note the contraction of the anterior fold (pectoralis major) and of the posterior fold (latissimus dorsi) of the axilla. Note the flabby weakened condition of the deltoid and supra spinatus. Every additional day that the arm is in adduction fixation this contraction becomes more marked and the weak abductors become less powerful.

3. If the joint has been injured so that there is danger of infection; if an arthritis or peri-arthritis is present; if a bursitis, which is only another form of peri-arthritis, exists, then the joint surfaces must be prevented from becoming adherent, or of pressing on each other, or contraction of the soft tissues or capsule about the joint must be prevented. This is accomplished by traction on the arm while the latter is held in abduction. The best means to do this is with a Thomas arm splint.

A point I have recently learned from experience is to apply my traction to the upper arm, leaving the elbow joint free to move at will.

4. Early passive motion should be started in these joints as soon as compatible with healing of soft tissues or fixation in case of a fracture. Very slight passive motion can be started within the first week. Active motion must be instituted gradually and gently. Recently I saw a surgeon illustrate the use of early active motion in a fractured head of the humerus. The case had been treated excellently, but on this date, four weeks after injury, he forcibly raised the arm above its right angle fixation and rotated it. The patient complained of pain bitterly, but the surgeon insisted that early force was necessary. Never under any condition exert active or passive motion to or beyond the pain point. Early motion to the prepain point is good; beyond that you run grave risk of starting an arthritis which will undo all the benefits of a properly conducted early treatment.

5. The application of hydrotherapy in the form of large hot fomentations is always beneficial in these injured joints; likewise baking of the joint by a Burdick baker. Diathermy, or deep baking of the joint, is indicated in the later stages; early it may create too great a reaction. Massage, gentle at first and gradually increasing, but never to the painful point, can go hand in hand with passive and active motion.

The measures outlined above relate to the early treatment of shoulder joint injuries instituted with a view of preventing the permanent disabilities so commonly following these injuries. They are practically the same measures adapted to the reconstructive treatment of old disability cases referred for the purpose of restoring function in a shoulder joint. Applied early they hasten recovery without the usual prolonged period of disability necessary to regain use of the arm. Applied late, after true or false ankylosis has occurred, they require perhaps operative treatment and months of abduction treatment, physiotherapy and all the other reconstructive efforts, and even then too often fail in their purpose.

In almost every type of deformity there are reconstructive principles and methods which will improve or restore function. The early application of these methods in the surgery of trauma will prevent a vast majority of these deformities.

SOME POINTS ON THE INNERVATION OF THE CHEST*

A. T. RASMUSSEN, Ph.D.,

Associate Professor of Neurology,
University of Minnesota

Minneapolis

REFERRED PAIN

The importance of knowing the fundamental nerve supply to the chest is especially evident when one attempts to work out the mechanism involved in referred pain and the reflexes which arise from irritation of the deeper structures of the body. It may be well, then, first to review briefly the general neuro-anatomy underlying these phenomena.

General plan of a typical thoracic spinal nerve and connections with the sympathetic system.—As you recall and as again illustrated in Figure 1, a typical spinal nerve gives off three branches just peripheral to the ganglion as it leaves the intervertebral foramen or very shortly thereafter. The first of these is a small twig called the recurrent nerve, which supplies the meninges about the spinal cord. The next branch is the dorsal (posterior) primary division of the nerve, which goes to the back muscles and overlying skin. The third is a rather delicate one called the ramus communicans, but which ought to be termed the *visceral ramus*, because it carries impulses from the spinal cord to the viscera and from the viscera to the spinal cord and to the other branches of the spinal nerve. If these simple facts, as illustrated in Figure 1, were kept in mind, the horror some physicians have for the sympathetic nervous system would largely disappear. At least the great bulk, if not all, of the sympathetic ganglion cells may be regarded merely as efferent (motor and secretory) neurones which have not remained in the gray matter of the central nervous system but have migrated out nearer the structures to be innervated, necessitating nerve fibers (preganglionic) for the purpose of carrying impulses from the central nervous system to these outlying motor and secretory nerve cells (Fig. 5), just as lower centers within the central nervous system are related to descending tracts from higher centers. The clearest presentation of this subject will be found in Gaskell's³⁵ book on the involuntary nervous system.

The only visceral afferent fibers which have been definitely identified merely course through these sympathetic ganglia and connecting plexuses without having any direct connection with the sympathetic ganglion cells and fibers coming from them. There is still some uncertainty about the terminal sympathetic plexuses; but in the main if you limit the term "sympathetic" to mean only sympathetic ganglion cells and the fibers which they produce,

Fig. 1.—Diagram of a typical thoracic spinal nerve and connections with sympathetic ganglia: 1, visceral afferent neurone (of first order); 2, cutaneous sensory neurone (of first order, related pericellular basket shown in greater detail at a); 3, neurone of second order in the pain tract from the skin; 4, association neurone which under lowered threshold of irritability might conduct visceral sensory impulses to the cutaneous pain tract; 5, neurone of the second order in the visceral afferent path; 6, visceral efferent (motor) neurone carrying impulses out of the central nervous system to sympathetic ganglia; 7, somatic motor neurone carrying efferent impulses directly out to voluntary muscles. Further explanation in the text.

the sympathetic nervous system is motor and secretory and the two subdivisions, autonomic or parasympathetic on the one hand and sympathetic proper (Fig. 5) on the other, are terms which apply only to this efferent mechanism and not to the visceral sensory fibers that happen to follow along with them.

Each ramus communicans is usually divisible into two strands. One of these, the white ramus, is largely composed of medullated fibers consisting of large visceral afferent and finer preganglionic or visceral efferent fibers. The other bundle, the gray

*Read by invitation before the Medical Staffs of the Parkview Sanatorium and the Lymanhurst School for Tuberculous Children, November, 1923.

ramus, is a sympathetic nerve in the strictest sense, composed almost wholly of non-medullated fibers destined for plain muscles and glands best reached by following along (and becoming mixed with) the main branches of the spinal nerves that go out to all parts of the body wall and limbs.

The main trunk of a spinal nerve (ventral or anterior primary division, shown diagrammatically in Figure 1) proceeds laterally and ventrally, supplying peripheral branches to the skin, musculature, costal pleura, etc.

From the above it is evident that afferent impulses from a particular viscus may enter a region of the spinal cord that also receives sensory impulses from a cutaneous area that is supplied by spinal nerves arising from that same region of the cord.

Theories of referred sensations.—Why a hyper-sensitive cutaneous area with actual pain develops as a result of irritation of some organ quite remote from the skin has been explained in various ways. The general idea is that there is a spreading of the impulses beyond the normal paths of conduction into tracts which ordinarily convey only impulses from the skin. Just where this spreading takes place is not clear.

One idea is that the non-medullated fibers which form a pericellular basket about dorsal root ganglion cells, as shown at 2 and in more detail at a in Figure 1, have been stimulated by the irritation and then transfer the impulses to a neurone whose peripheral process terminates in the skin. Central conduction would hence be the same as if the seat of the irritation were in the skin. But the fibers thus terminating as pericellular baskets in the dorsal root ganglia have never been shown to carry such impulses nor even to be visceral afferent.

A second theory is that the excessive stimulation of visceral afferent fibers lowers the threshold of irritability in the central nervous system so that impulses spread into pathways usually only involved in cutaneous stimulation. This can be readily understood by referring to Figure 1. Normally the resistance at the synapse between the visceral afferent fiber (neurone 1) and neurone 4 is so high that the path of conduction is to neurones 5 and 6; but if the resistance in the path involving association neurone 4 is greatly reduced, impulses may stray to neurone 3 and thence to the conscious center for cutaneous pain just as if the impulse originally started in the sensory fibers of the skin. Or

the lowered threshold may result in impulses ascending much higher than normally but over already existing tracts. Due to lack of experience in accurately locating the seat of visceral excitation, it is falsely located in the skin connected with the particular region of the central nervous system especially closely associated neurally with the irritated viscera.

The third and least plausible explanation is that during central conduction of visceral afferent impulses, say over neurone 5 in Figure 1, the impulse spreads into an adjacent bundle of fibers, as those from neurone 3 of Figure 1, which regularly are conducting impulses from the skin. For further discussion of this subject reference may be made to Head's article listed at the end of the paper.³⁹

Example of referred sensations.—The best example of referred sensations to illustrate the involved neurology is in connection with the diaphragm. As shown in Figure 2, the central portion of the diaphragm is supplied with sensory fibers by the

Fig. 2.—Diagram showing where pain is referred as a result of stimulating various areas on the diaphragm. a, Surface view of diaphragm; b, cutaneous areas to which diaphragmatic pain is referred. When area P is irritated the pain is located at P'. When area S is irritated the pain is referred to S'. (Modified from Capps.)

phrenics which are branches primarily of the fourth cervical nerves. The rim and posterior third, however, is supplied by the lower six thoracic nerves. Cope²¹ has definitely shown that if the phrenic region is irritated the sensation is referred to the trapezius region where the skin is supplied by the fourth cervical nerve, whereas if the periphery and posterior portion of the diaphragm is stimulated the sensation is referred to the lower chest and

upper abdominal wall, i.e., to the cutaneous region supplied by the lower thoracic nerves. .

SUMMARY OF THE NERVE SUPPLY TO THE CHEST OF INTEREST TO CLINICIANS

The costal portion of the parietal pleura.—The costal pleura is supplied by the deeper branches of the intercostal nerves. It is sensitive to painful stimuli, but not to ordinary touch and temperature (Capps,¹⁵ Hoffmann⁴¹). The pain is of the usual irritation type characteristic of peripheral nerves. It is located fairly accurately over the particular intercostal nerve involved, although localization is more accurate in the ventral and lateral regions than in the dorsal.

The diaphragm.—The phrenic nerves are the chief if not the sole motor supply to the diaphragm as is evident from the paralysis resulting from their complete severance. Blocking the phrenics with novocain has been done for relief of severe attacks of singultus (Wegele⁴²), while Báron³ has done it to stop coughing due to injury to the diaphragm. Neuhöfer⁶¹ recommends phrenicotomy under certain other conditions where immobility of the diaphragm is desirable. A number practice it as an aid in curing pulmonary tuberculosis (Alexander,¹ Goetze,³⁷ Frisch³⁴ and others). Some indications and results of radical phrenicotomy have recently been published by Fischer.³³

The afferent supply of the diaphragm, as has already been mentioned in connection with referred sensations, is by the phrenics and lower six thoracic spinal nerves. The reason for this dual arrangement is embryological. The central portion of the diaphragm arises from the septum transversum, which descends from the cervical region, carrying its cervical (phrenic) nerve supply with it. The periphery and dorsal portion comes from folds arising from the adjacent body wall where the lower thoracic nerves are involved.

The phrenic nerves, however, supply afferent fibers not only to both surfaces of the central and greater portion of the ventral two-thirds of the diaphragm but also to the capsule and ligaments of the liver and structures in the suprarenal region of the abdomen. Cope,²¹ Orr,⁶³ Westphal⁸³ and others have recently called attention to the diagnostic value of phrenic shoulder pain in acute abdominal diseases that affect the hepatic, gastric, pancreatic and upper renal regions. Thus a point of tenderness in the neck over the right phrenic may be sig-

nificant in Weil's disease (acute febrile jaundice), inflammation of the biliary tract, enlargement of the liver with stretching of the capsule, as well as diseases involving the right side of the diaphragm. Air injected into the abdominal cavity, if allowed to rise to the diaphragmatic region, produces phrenic shoulder pain.

Lungs and deep air passages.—The motor nerve fibers to the bronchial musculature arise largely from the sympathetic nerve cells of the pulmonary

Fig. 3.—Diagram showing the probable reflex arc from the lungs over the vagus nerve to the cervical and thoracic region of the spinal cord and out to the sternocleidomastoid, trapezius, diaphragm and other muscles.

plexus outside of the lungs, but also to some extent from ganglion cells scattered along the larger bronchi, particularly as far as the origin of bronchi of the third order. These ganglion cells in turn are connected mostly with fibers from the homolateral vagus and to a slight extent with either the contralateral vagus or upper thoracic spinal nerves and sympathetic chain (Larsell,⁴⁹ Larsell and Mason⁵¹).

The bronchial mucous glands are apparently innervated by the same source as in case of the musculature.

The vasomotor nerves to the blood vessels of the lung are derived largely from the second and third thoracic sympathetic ganglia of the main sympathetic trunk (Fig. 5) (Möllgaard,⁵⁹ Larsell and Mason⁵¹). Luckhardt and Carlson,⁵³ however, found vasoconstrictors to the lungs in the vagus of frogs and turtles. In the turtle the vagus also contains vasodilators to the lungs. Evidently there may be variations in the vasomotor mechanism in animals of different species.

Afferent nerves and sensory endings are found in the epithelium of the primary bronchi and at the point of bifurcation of the succeeding order of bronchi nearly to the alveolar duct, in the muscles of the bronchi and in the walls of the larger pulmonary arteries (Larsell,^{48, 49, 50} Dogiel²⁶). The bronchoscope and even more slender instruments inserted deeply in the respiratory passages may pro-

particular lung when the corresponding vagus is cut (Larsell and Mason,⁵¹ Larsell⁴⁹), indicating that they come largely from the homolateral vagus. The rest come either from the opposite vagus or

Fig. 4.—Diagram showing another probable reflex path from the lungs to the sternocleidomastoid, trapezius and diaphragm as a result of irritating the afferent fibers from the upper thoracic spinal nerves.

duce coughing (Jackson,⁴² Larsell⁵⁰), although the more distal portion of the respiratory tree is less sensitive than the trachea and primary bronchi.

Most of these afferent nerves degenerate in a

Fig. 5.—Diagram of the so-called sympathetic system proper (thoracic-lumbar outflow of general visceral efferent fibers) showing the functional significance of the sympathetic trunk and its connections.

from the upper thoracic nerves through the sympathetic system as shown in Figure 4. Stimulation of the deep air passages with irritating gas modifies respiration even after sections of both vagi (Craigie²²) and Pike and Coombs^{65, 66} have shown that respiratory movements are markedly disturbed when the dorsal roots of the thoracic nerves are cut. These experiments emphasize the importance of these afferent fibers in the spinal nerves.

The central connections of the afferent fibers of the vagus are diagrammed in Figure 3. This cut was designed to show the probable neurological basis for the referred pain in the cutaneous region of the fourth and adjacent cervical nerves resulting from lung disturbances and the spasticity of the trapezius, sternocleidomastoid and diaphragm in tuberculosis of the lung (Pottenger⁶⁸). Another possibility is shown in Figure 4, although since most of the afferent fibers from the lungs (exclusive of the pulmonary pleura) are vagus in origin,

the first pathway (Fig. 3) is probably the most important.

Pulmonary pleura.—In contrast to the rest of the lung, the pulmonary pleura is supplied with afferent fibers largely, if not entirely, from the upper three or four thoracic spinal nerves (especially the second and third). These course through the white rami into the sympathetic trunk of the upper thoracic and lower cervical region, leaving the trunk in the neighborhood of the inferior cervical sympathetic ganglion (Edgeworth,²⁹ Möllgaard.⁵⁹ Ranson and Billingsley,⁷¹ Hoffmann,⁴¹ Larsell⁴⁹). They course in the periarterial plexus along the pulmonary artery. Larsell finds that these nerves are confined to the margins of the interlobular regions and are most numerous in the dorsal margins near the hilus of the lung. They terminate in sensory endings of various types. Large areas in contact with the parietal pleura are practically devoid of nerves. This accounts for the general findings that the surface of the lung is insensitive to mechanical and chemical stimuli (Capps¹⁵), although Hoffmann⁴¹ found a small area near the hilus of the lung that seemed sensitive, as one would expect from the presence of sensory nerves especially in this region. Electric stimuli may be perceived and cold (20° C.) and warmth (50° C.) cause coughing when applied to the visceral pleura. Pain is aroused only when adhesions are present, evidently because the parietal pleura becomes involved. A more careful examination of the special regions where there are sensory nerve fibers is needed.

Mediastinal or pericardial pleura.—Capps'¹⁵ experiments on human subjects indicate that the phrenic supplies the pericardial pleura. Its irritation causes referred pain in the fourth cervical cutaneous region as in irritation of the central portion of the diaphragm and upper abdominal tissues, which are also supplied by the phrenics.

The pericardium.—This membrane is also largely supplied with afferent fibers from the phrenics, although cutting these nerves does not entirely abolish the rise in blood pressure produced by stretching or pinching the pericardium. Hence some afferent fibers evidently come from the thoracic spinal nerves via the sympathetic system (Luschka,⁵⁴ Ramstrom,⁶⁹ Capps,¹⁵ Mathieson⁵⁶).

Heart and great vessels.—Time will not permit any detailed statement of the motor nervous mechanism of the heart. The presence of intrinsic gan-

glion cells and their fibers more or less diffusely scattered as well as in groups near and within the sinoatrial node of Keith and Flack, the atrioventricular node and its continuation, the atrioventricular bundle of His, is generally recognized. These ganglion cells send fibers to the cardiac muscle cells. They receive a rich supply of pericellular nerve endings (preganglionic fibers) mostly of vagus origin.

These extrinsic nerves from the vagus are inhibitory and arise, according to Malone,⁵⁵ from the middle portion of the cell column in the medulla oblongata known as the dorsal nucleus of the vagus. Eyster and Meek³¹ have obtained good evidence that the vagus normally exerts its greatest influence on the sinoatrial node, next upon the atrial portion of the atrioventricular node and still less upon the ventricular portion of the latter node. Bachmann² has described in considerable detail the distribution of each vagus within the heart.

The accelerator nerves leave the upper thoracic region of the spinal cord as small medullated fibers which pass through the ventral roots and white rami of the upper three or four thoracic nerves and into the sympathetic trunk, where most of them terminate about the cells of the upper thoracic and lower and middle cervical sympathetic ganglia (Fig. 5). The cardiac accelerator nerves arise from these ganglia and in connection with the cardiac fibers from the vagus form the cardiac and coronary plexuses.

A few preganglionic accelerator fibers do not end in the sympathetic ganglia of the main trunk as just described, but continue on to the cardiac ganglion of Wrisberg located in the superficial cardiac plexus. The postganglionic non-medullated fibers terminate in distinct endings on the cardiac muscle cells.

The vasomotor supply to the coronary vessels and aorta is from the upper four or five thoracic sympathetic ganglia, although there is some evidence that vagus irritation may cause spasms of the coronary arteries, thus indicating some vasoconstrictor fibers in this nerve. Langendorff (see Higier⁴⁰), from experiments with adrenalin, concluded that the most evident effect produced by the thoracic sympathetic ganglia on the coronary vessels is dilatation.

Afferent nerves and nerve endings are abundant in the heart (Dogiel,²⁷ Smirnow,⁷⁹ Valedinsky,⁸¹ Michailow⁵⁷). Some of these fibers are from the

vagus. A special bundle to the aorta, usually designated as the depressor nerve, is of importance because the claim has been made that this can be isolated and cut with some success for the relief of angina pectoris of basal aortic origin. The rôle of the depressor nerve in slowing the heart and relaxing the arteries is well known.

Many of the afferent fibers to the heart come, however, from the upper thoracic spinal nerves, mostly over the upper three or four white rami communicantes (Ranson and Billingsley⁷¹). Clinical evidence indicates that they come mostly from the left side. Daniélopou²³ found that he could relieve most of the pain in angina pectoris by cutting the dorsal root of the second thoracic nerve on the left side. In diseases of the ventricles and ascending aorta the pain is usually referred to the left upper thoracic and left third and fourth cervical cutaneous areas, although it may spread to the right side (Pottenger⁶⁸). This is also evidence that the ventricles and base of aorta are closely connected by afferent nerves with the gray matter of the upper thoracic and mid-cervical region. Similar evidence shows that the atria are connected with the thoracic cord as low as the seventh thoracic segment. The pain in mitral stenosis with dilatation of the left atrium, for example, is referred mostly to the sixth and seventh thoracic cutaneous segments. Since the atria of the heart are derived from the venous or caudal end of the embryonal heart, the connection of the atrial portion with a more caudal region of the spinal cord is to be expected.

That these spinal fibers traverse the lower cervical and upper thoracic regions of the sympathetic trunk is supported by the relief afforded by surgical removal of these portions of sympathetic chain as has been done by Jonnesco⁴³ and others (Coffey and Brown,¹⁹ Brown,⁹ Brünig¹¹) in angina pectoris due to aortic and cardiac lesions.

Esophagus.—The literature on the nerve supply to the esophagus has recently been exhaustively reviewed by Carlson.¹⁷ His own experiments confirm the idea that the vagus has both motor and inhibitory control over the esophagus and cardia. If in strong tonus, vagus stimulation causes inhibition and if relaxed the same stimulus causes contraction.

Contrary to the general notion that the splanchnic nerves have nothing to do with this region of the alimentary canal; Carlson found that in the cat the same results may be obtained by splanchnic stimu-

lation as is obtained by stimulation of the vagus. In the dog only contraction resulted, while in the rabbit only inhibitory effects were obtained from stimulating the splanchnics. Adrenalin produces both contraction and inhibition, depending upon the state of tonus at the time.

On the whole, it is necessary to assume that both the vagus and the splanchnic nerves innervate the thoracic portion of the esophagus and the cardia of the stomach. This is one more instance where the antagonism generally assumed to exist between the parasympathetic (or autonomic) and sympathetic system proper has been shown to be at least greatly overdrawn.

The sensory properties of the esophagus has been most intensively studied by Boring.⁶ His results show that the mucous membrane throughout its entire length is sensitive to thermal, mechanical, chemical (alcohol and hydrochloric acid, but not to oil of peppermint nor mustard and pepper suspensions) and electrical stimuli; 60° C. gives sensations of heat, and extreme cold and heat cause pain. The upper esophagus is more sensitive than the lower portion. When the thoracic portion is excited with electrical stimuli by a small active electrode sensations are first noticeable in the arm where a large indifferent sponge electrode is applied, although this indifferent electrode covers more than fifty times as much surface as the small active electrode covers in the esophagus.

The sensations from the esophagus are generally referred too low over the lower third of the sternum and middle region of the upper half of the epigastrium when the lower third of the thoracic esophagus is stimulated. When the upper third of the thoracic esophagus is stimulated the sensations are more accurately located but usually too high and frequently in the throat region.

The afferent nerves involved are largely supplied by the vagus. The lower portion at least receives some fibers from the splanchnics (fifth to tenth thoracic spinal nerves). This explains the reference of the sensations from this region of the esophagus to the epigastrium.

The thymus.—While nothing specific can be said of the functional significance of the nerves to the thymus, the chief anatomical findings show that there are fine non-medullated nerves around the blood vessels and in the connective tissue of the capsule and trabeculae. Sympathetic fibers from the upper thoracic and cervical sympathetic chain,

in connection with small filaments from the vagi, descend along the thyroid gland, cardiac nerves and thymic blood vessels into the gland. Occasionally some of these fibers follow the phrenic nerves for a distance (Braeucker⁸).

Apparently the thymus is insensitive to ordinary stimuli, but when inflamed it produces pain which is poorly localized. This pain may in some cases be due to encroachment upon neighboring structures such as the great vessels, lungs, phrenics, vagi, recurrent, laryngeal nerves, etc. (Phillips,⁶⁴ Lemon⁵²).

The thoracic sympathetic trunk.—In connection with chest diseases, attention may finally be called to the possibility of involvement of the sympathetic trunk and related nerves, since they lie just under the parietal pleura through the greater portion of the thoracic cavity. Figure 5 gives some idea of the functional significance of this great system. It is a relay mechanism between most of the viscera of the entire body on one hand and the central nervous system on the other. The anatomical connections between the sympathetic trunk and the spinal cord are the white rami communicantes, which are limited to the thoracic and upper two or three lumbar segments, that is, almost wholly in the thoracic region. That many visceral disturbances might be brought about by the encroachment of chest abnormalities upon this system is thus apparent. Dilatation of the pupil due to pressure on the sympathetic trunk is a common example; however, this may occur from trauma to peripheral nerves in many other parts of the body (Byrne^{12, 13, 14}).

PRELIMINARY NOTE: A STUDY OF THE
NERVOUS SYNDROME AND THE BLOOD
SERUM IN PERNICIOUS ANEMIA AS AN
AID IN DIAGNOSIS BEFORE RECOGNIZ-
ABLE CHANGES ARE APPARENT*

C. EUGENE RIGGS, M.D.

St. Paul

In 1896 I reported a case of pernicious anemia¹ before the American Neurological Association at Philadelphia. The pathological findings were carefully worked out by Dr. Louis B. Wilson. The first contribution to this subject in this country was made by Putman in January, 1891. Three months later Dana reported a case; his second case was reported in 1899. My case with the neuropathological findings is the third in American literature. In 1913,² I read a paper before the nervous section of the A. M. A., at Minneapolis, on "Some Nervous Symptoms of Pernicious Anemia." I emphasized the great importance of these symptoms, stressing their distinctiveness, especially the subjective sensory disturbances; their constancy, their progressiveness and their early appearance. I stated that the symptoms may resemble those observed in peripheral multiple neuritis. I intimated that the sclerosis was apparently of vascular origin and might precede by months or even years the appearance of the blood picture. I illustrated this by reporting a case of Bramwell in which the cord symptoms preceded by three years the blood picture which two weeks before death showed no characteristic features of pernicious anemia. I also stated "that the personal equation determines whether the pathologic process be a pernicious anemia with or without a cord lesion or simply a diffuse degeneration of the spinal cord." "It occurs to me," says Dr. Woltmann,** "that patients may die of neurologic changes without ever developing anemia and yet have the same disease fundamentally that we refer to as pernicious anemia. The work of Hurst, Curschmann, Weinberg, and others would indicate that the achylia represents a primary constitutional familial deficiency. Naegeli has pointed out that homolysis is not always necessary and looks on a primary bone-marrow deficiency as the important conception. The laboratory evidence bears out the view expressed in your paper of 1913."

**Personal communication.

*Presented before the annual meeting of the Minnesota State Medical Association, St. Paul, October, 1923.

The nervous picture in pernicious anemia is ill defined, protean, variable and progressive. Subjective sensory disturbances are usually the earliest manifestations. Beware of paresthesias, and numbness in the fingers and toes in elderly people; they may precede by months the more obvious changes. Even though the blood picture is wanting, yet the presence of such a cardinal symptom as the loss of deep sensation (loss of vibration sense, of sense of posture and inability to appreciate passive movements of fingers and toes) which is absent in only a small minority of the cases is presumptive evidence that we are dealing with this intractable malady. Touch, temperature and pain are usually normal in the early stages, not being involved until late in the course of the disease or possibly not at all. (Cadwalader?)³ It may masquerade as a multiple peripheral neuritis. Recently I observed a case where a hysterectomy had been performed in the vain hope of curing a progressively increasing weakness and a marked sensory disturbance of two years standing. The nervous syndrome is entirely dependent upon the extent the central nervous system is involved. Taylor* states "that the cord changes are much more frequently associated than we have been accustomed to assume and this would be shown were we more skillful in our blood examinations and more accurate in our histological studies." Some time ago, I read a paper before this Association on the "Subacute Combined Degeneration of the Spinal Cord," showing that similar cord changes may occur independently of pernicious anemia due to infections and a great variety of causes. Hunter describes a case of sub-acute combined degeneration of the cord with patches of croupous enteritis in the jejunum. Some 80.6 per cent of patients suffering from this disease, according to Woltman,⁴ develop nervous tissue change. Degenerative changes, once having occurred, never recede, even though there be a remission and the blood picture shows little or no abnormality; a subsequent fatal attack is only a matter of time. Courtney⁵ repeatedly calls attention to the marked dissociation between the blood state and the cord lesions. He has observed the lesions go steadily on in spite of marked improvement on the part of the blood. Sensory disturbances, both subjective and objective, may occur in an apparently normal cord. (Hamilton and Nixon.)⁶ Homer wrote twenty-four

books about the wanderings of Ulysses. As a college student I wished his labors had been less prolific. I do not wish to imitate him. I shall not, therefore, discuss the etiological, clinical or pathological phases of this disease. That would be Homeresque. The literature of this subject is most voluminous and is at the command of all. My purpose is to call your attention to some recent work done on the blood serum of these patients, making possible a diagnosis long before obvious changes occur, which, if confirmed, must possess a great value, not only in the early diagnosis which at present baffles the most clever clinicians, but also in enabling us to differentiate between it and the secondary anemias. In this work which has so many of the characteristics of pioneering, a healthy skepticism must be observed. No one is more conscious than my associates and myself that this preliminary note dealing with the recent work on the blood serum as an aid in early diagnosis is far from satisfactory. It will require years where we have only had months to confirm or reject this contention. The unreliableness of our present methods of procedure and the great boon it would be to both patient and doctor has seemed to us sufficient justification for our present endeavor. While it may be an illusion of hope, yet it is far from being inconceivable that if detected in its incipency pernicious anemia might be arrested.

The original work done in this country by Putman, Dana, Wilson and others dealt with the fundamentals of its neuropathology. These have been verified and added to by subsequent workers. Recently, Dr. Hassin,⁷ Chicago, has done some very remarkable histological work on multiple sclerosis and has made most interesting comparisons between the lesions of this disease and those in the cord changes of pernicious anemia. In Bramwell's case the clinical symptoms were characteristically those of multiple sclerosis. Hassin's investigations lead him to believe that pathologically the changes in subacute combined degeneration and multiple sclerosis are the same; that it is almost impossible to distinguish between them. The degenerative change in subacute combined degeneration, according to him, is "more powerful, more striking than in multiple sclerosis"; while in the former the axones degenerate in systems, in the latter they go as single fibers. (Barker.)

Globus and Strauss⁸ regard the pathologic process as degenerative in character due to a toxin of

unknown origin. They also state that the histologic picture is in the main similar to that found by Hassin in multiple sclerosis for this purely degenerative condition.

Taylor states that subacute combined degeneration is never truly systemic; that it is always diffuse—outside the actual system tract. Clinically one cannot differentiate between the nervous syndrome of pernicious anemia and the cord degeneration arising from other causes; if under these conditions the blood serum enables us to do this, it will be a notable advance. To the general practitioner who sees these patients first, it will be a procedure of inestimable value. Hassin suggests that future studies of multiple sclerosis must be confined to the biological, pathological and serological investigations of the spinal fluid. Because of the pathological similarities in these two diseases, a like method of research in the latter disease is worthy of consideration.

Since the degenerative process occurs in the medullary portions of the brain with about the same frequency that it does in the spinal cord,⁹ mental abnormalities are common. In 650 necropsies on the insane in Michigan, Barrett found pernicious anemia present in 2.3 per cent. Cabot in 647 cases noted the incidence of mental symptoms in 15 per cent and Weisenberg states that they are present in 40 per cent of the patients (Woltman). Eighteen years ago, Langdon pointed out that the mental symptoms like those of the cord may precede the anemia. These manifestations he designated as "pre-pernicious anemia." I have seen an apparently secondary anemia overshadowed by a recurrent melancholia, only to reveal its true nature after a tonsillectomy. There is no distinctive psychosis in pernicious anemia. The mental symptoms are indicative of a "toxic-organic" process affecting the central nervous system. If the cerebral cells lack oxygen, as may occur in severe cases of pernicious anemia, permanent mental¹⁰ changes are observed. Darden and Hall¹¹ think that the mental disturbances directly dependent on pernicious anemia should be classed as exhaustive or toxic psychoses. Where manic-depressive insanity and dementia precox states occur, the anemia simply acts as an exciting cause in a predisposed individual.

Constantly has the physician striven to increase his knowledge of the human body. For almost two and one-half centuries has he used the microscope to reveal its minute structure. For a century has he

employed the stethoscope to aid the ear in recognizing the sound of a disturbed mechanism. Indeed, the value of the clinical thermometer was not appreciated until the middle of the nineteenth century. The body, fundamentally, is a chemical machine. The laboratory has opened up new vistas and marvelously increased our knowledge of disease. It was the laboratory that gave us our first clear conception of trench nephritis—perhaps the greatest cause of loss of man-power during the great war—and it is through the laboratory that this study of the blood serum opens up a fascinating field of research, with an opportunity of rendering effective service to a class of long-suffering patients, with a possibility of this investigation being a milestone on the path of progress in biochemical research which ultimately will lead to a revelation of the cause of this intractable malady.

"In full fair tide let information flow—

That evil is half cured whose cause we know."

About 1920, Brockbank¹² first noticed that the color of the plasma or serum of pernicious anemia differed from that seen in the plasma or serum of normal blood or of any other anemia. Since making the observation he says, "I have used it regularly in the diagnosis of pernicious anemia and found it a most useful and reliable, if not a pathognomonic test of this anemia." The serum, according to this observer, is always a definite yellow color, varying in tint from that of a cowslip to the buttercup yellow of Canada balsam, whilst the serum of all other anemias is much paler and resembles straw-colored water." He states that from the observation of a score or more of cases of pernicious anemia, and twice the number of other anemias, a diagnosis of pernicious anemia from other forms of anemia can be made. The outstanding fact is that the serum of severe secondary anemia is a pale straw-color, not yellow. He also says that "there is no question of any pink color in the deeper colored yellow serum—nothing whatever to suggest the presence of any trace of hemoglobin or hemolysis nor is it of a bile pigment tint." The occurrence of hemolysis must be carefully guarded against. This can be avoided by "drawing 0.5 c.c. of sterile five per cent sodium citrate solution through the sterilized needle into the sterilized syringe and withdrawing the piston to its full extent, thus rinsing the barrel of the syringe with the citrate solution, which is then expelled from the syringe."

Panton, in his "Clinical Pathology" states that "the bile color of some serums is more closely simulated by the greenish yellow pigment present in the serum of nearly all cases of pernicious anemia." Stengel,¹³ in a discussion of secondary hypoplastic anemia refers to the yellowish color of the blood plasma in pernicious anemia, stating that the above types present many findings of pernicious anemia, except that the blood plasma has not the definite yellow color. Brockbank thinks that the cause of this color of the serum is due to oxyhemoglobin. He demonstrated this by the examination of the serum with a pocket spectroscope which revealed two very distinct absorption bands in the position of those of oxyhemoglobin. There was a much less distinct narrow third band farther to the right in the green in some specimens. Later he checked up the pocket spectroscope with a laboratory instrument, with which the wave lengths of the definite absorption bands could be measured. In all the cases they were identical with the absorption bands of oxyhemoglobin. In normal blood serum the same absorption bands were present, though generally less distinct. No absorption bands were seen in any other form of anemia. The absorption bands were present in all specimens of pernicious anemia examined with the exception of the very pale ones. These bands are very distinct in the deeper colored serums. Continental workers have not confirmed the spectroscopic researches of Brockbank. Hematin has been observed as a pathological constituent in the serum of pernicious anemia and the yellow color has been explained by a small addition of the bilirubin to the oxyhemoglobin dissolved in the serum.

The Ariadne clue to the complete knowledge of this disease lies along the pathway of biochemistry. Much splendid work has been and still is being done along this hopeful line. Duke and Stofer¹⁴ give as a probable explanation for the apparently relatively good color of many patients with pernicious anemia, in spite of a low blood count, the fact that the capillary red blood counts on these patients were on an average 17.6 per cent higher than similar counts on venous bloods. At the same time, the capillaries contain also an increased number of macrocytes.

Gettler and Lindeman¹⁵ give the results of the chemical and physical analysis of the blood in 87 cases of pernicious anemia, showing such findings

as increase in non-protein nitrogen, urea and creatinin values as well as greatly increased uric acid and amino-acid content. Other interesting findings are high blood sugar, subnormal alkaline reserve, as well as low refraction and specific gravity. Similar studies, together with those of the functional capacity of the various organs, have been made by Kahn and Barsky.¹⁶ McMaster, Rous and Larimore¹⁷ have shown that the marked siderosis of the liver parenchyma that occurs during pernicious

anemia is caused by an injurious agent derived from the gastro-intestinal tract. Recent studies by Gibson and Howard¹⁸ show low blood and plasma cholesterol figures as well as low urea, and moderate ammonia nitrogen and high uric acid figures. A study of severe cases of secondary anemias by Mark¹⁹ shows the similarity of the blood picture between many cases of secondary anemia and those of pernicious anemia, and the importance of developing more pathognomonic signs; while the high color index is very suggestive, recent observations have convinced him that certain patients with that disease may at sometime in their course present a low color index. Wearn, Warren and Ames²⁰ find that red blood cells from donors in Group IV transfused into patients in Group II with pernicious anemia and

anemia secondary to nephritis remain in the circulation an average of 83 days. Ashby²¹ has shown that the life of the transfused corpuscle extends thirty days or more. Denny²² states that in ten cases of pernicious anemia the total blood volume was reduced in all but two cases, while the plasma remains normal. The examination of the duodenal contents for an increase in the urobilin and urobilinogen content in patients with pernicious anemia as emphasized by Schneider²³ and later by Giffin, Sanford and Szloppa,²⁴ is a valuable

procedure, but this test, unfortunately, is too complicated for the use of the average practitioner. It may be regarded as confirmatory evidence not in itself diagnostic. Increased metabolic readings in pernicious anemia, as observed by a number of men, while most interesting, are disappointing as regards differential diagnosis. Leschke and Neufeld²⁵ find no difference in the examination of washed red blood corpuscles in pernicious anemia, secondary anemia, polycythemia, hemolytic icterus

and in normal individuals. They also state that the brownish color of the blood in pernicious anemia is accordingly not referable to a degeneration of the hemoglobin, but is more probably due to the presence of waste products of the blood pigment like the dark yellow color of the serum. The responsible disintegration products of the blood pigment are methemoglobin, hematin and especially bilirubin. Dr. Bernheim* feels that the icterus index offers a very important differential point in patients with pernicious anemia, it being about 10 in the average case, whereas in secondary anemia it ranged between 2.3 and 3.9 in cases examined by her. DeWitt Stetten²⁶ cites several instances of pernicious anemia with an icterus index above normal.

While this research work is fascinatingly interesting

and possesses great potentialities and possibly the ultimate solution of this most perplexing problem, yet unfortunately it does not enable us to make a diagnosis. Happily, this is just what an observation of the blood serum does; it is a simple procedure at the command of every medical man; no annoying delay, no complicated laboratory technic. The simplicity of this method is so marked and its diagnostic importance so great, that the astounding fact is that its real significance was not recognized long ago.

*Personal communication.

Early Diagnosis of Pernicious Anemia from Blood Serum.

The following twenty cases are excellent illustrations of the anemias, the first ten being primary, the remainder secondary. Of the former, the picture was definite and the diagnosis not to be questioned.

CASE I. J. D. Age 37 years. Past history negative. Present illness has extended over the last two years. Patient says that the first thing he noticed was shortness of breath on running up stairs. This has gradually become worse, so that now when he walks up stairs he gets extremely short of breath. If it is a long flight he must stop and rest, not from weakness but from lack of air. For the last three months patient has noticed that his strength has been getting less and that he has not been able to do his work as usual. Finally, he had to give up his position a few days ago because of his weakness. He would be extremely tired at night. On any extra exertion, for the last six months, patient has noticed that his heart would beat very fast and that he would have a dull aching precordial pain. This would last only about ten or fifteen minutes after he started to rest. Of late he has noticed that on even slight exertion this pain would develop. For the last year he has noticed numbness in legs and hands. This is worse in feet but also spreads up the legs; days that he does not have any feeling in the feet. For the last four or five weeks he has had diarrhea; having four or five watery stools at night. Was in hospital one year ago for the same trouble. After leaving the hospital he felt fine for four or five months, until about September; since then his symptoms have been getting progressively more marked. Physical examination: Marked pallor of skin and mucous membranes. Tonsils, atrophic, chronic, infected. Spleen, not palpable. Positive findings. neurological: Right knee jerk, —2 on 1, 2, 3, 4 basis; left knee jerk, —4 on 1, 2, 3, 4 basis. Achilles, right —4; left —4. Sensation, —2 —3 to pain, lower extremities on 1, 2, 3, 4 basis; —1 —2 to touch, lower extremities on 1, 2, 3, 4 basis. Vibration —4 lower extremities. Laboratory: urine negative; stools negative. Absence of free HCl in gastric contents. Blood count: Hemoglobin, 40%; r. b. c., 1,490,000; leucocytes, 4,000; differential, 100; polymorphonuclear, 56%; lymphocytes, 43%; eosinophile, 1%; poikilocytosis marked; anisocytosis marked; polychromatophilia marked; basophilic stippling marked; red cells have anemia centers. Nucleated reds present in large numbers. Diagnosis: Pernicious anemia.

CASE II. Mrs. J. D. Age 58 years. Influenza, 1918. Patient has been delicate for past eight or ten years. Under weight; has been pale as long as she can remember. Apparently not more marked recently. Moderate weakness. No history of sore tongue; no paresthesias; no numbness until one month ago, since when slight numbness of lower legs. Several attacks of upper right abdominal pain past year. Last attack one month ago and associated with vomiting. Physical examination: Marked pallor of skin and mucous membranes; malnutrition; spleen not palpable; tenderness right upper quadrant. Neurological, negative. Laboratory findings: Urine, negative; x-ray gallbladder shows distended gallbladder with two gallstones. Blood examination: Hemoglobin, 33%; erythrocytes, 1,740,000; leucocytes, 4,600; differential, 100; polymorphonuclear, 44;

lymphocytes, 42; large mononuclear, 10; transitional, 2; eosinophile, 2; poikilocytosis, xx; anisocytosis, x. Diagnosis: 1. Pernicious anemia; 2. Cholecystitis with cholelithiasis.

CASE III. Mr. G. A. Age, 43 years. History: Present complaint, weakness and pallor. Past history negative as to illnesses or operations. Patient states that his health was very good up to about two years ago, at which time he developed a severe cold, following which he had frequent colds in his chest with indefinite body pains in his neck and arms. His present illness started about one year ago, beginning with a numbness of the legs which has been constantly present and gradually growing worse. During this time the patient has been getting weaker. About three months ago he noticed that his skin was becoming yellow. He has been taking iron ampoules and regulating his own diet but has noticed no improvement in his condition. Appetite has been good; no nausea or vomiting, no colic, bowels and stools have been normal. Cardio-respiratory: edema, palpitation and dyspnea one plus. Patient states that swelling of the feet and legs has been quite marked and that he has had to buy larger trousers and shoes because of it. Patient uses tea, coffee, tobacco and snuff. No history of sore tongue. Best weight, 170; present weight, 162. Physical examination: Tonsils buried and chronically diseased. Septum deflected moderately to the right. Teeth show alveolar abscesses. Skin shows a marked pallor of the lemon yellow type and the mucous membranes are pale. Anus shows external hemorrhoids with fissure. Poor co-operation on sensory examination (probably negative). Joint lower extremities apparently —2 —3. Vibration —3 —4. Patient's mental condition questionable. At times he seems to be somewhat irrational and at all times is uncooperative. Laboratory findings: urine, negative; blood, 6-19-23, hemoglobin, 34%; r. b. c. 1,250,000; w. b. c. 6,000; color index, 1.3, few nucleated reds, marked anisocytosis, moderate achromia, marked poikilocytosis, polychromatophilia and stippling. Diagnosis: Pernicious anemia, infected tonsils, alveolar abscess, external hemorrhoids with fissure.

CASE IV. Patient, Mr. L. W. Age 62. Present complaint is marked weakness, duration past six months. Past history is negative for illnesses and operations. For the past four years the patient has had spells of weakness followed by periods of comparative good health. Last fall, during one of the weak spells, the patient vomited and once during the winter he vomited blood. Patient states that his hands and feet have felt numb, that they feel raw now and that his legs are very weak. The patient also complains of a pain over the gallbladder region, which has been present for the last three or four years. States that the onset of the whole trouble started with a severe cold. Appetite poor with occasional nausea and vomiting. No colic, bowels constipated with stools hard. No edema, moderate palpitation and dyspnea. No history of sore tongue. Physical: Nose shows very poor drainage with a deflected septum which practically blocks the right side. Teeth, caries and pyorrhea. Tongue shows marginal smoothness. Skin sallow with a lemon yellow tint. Mucous membranes poor color. Complete neurological not done because of patient's weakened condition. Joint sense of extremities, —2 —3; vibration sense, —3. Laboratory findings: x-ray of stomach and heart, negative;

urine, negative; gastric analysis shows a fair digestion, mucus three plus, very slight residue, no free HCl, combined HCl 8, total acidity 8, no lactic acid, no occult blood; blood Wassermann, negative; 6-6-23, hemoglobin, 56 per cent, r. b. c. 2,200,000, marked anisocytosis, slight achromia, a few shadow forms, no nucleated reds, moderate poikilocytosis, urea 22 mg., sugar, .125 mg.; 6-13-23, hemoglobin 66 per cent, red blood cells 1,800,000; 6-25-23, hemoglobin 45 per cent, r. b. c. 1,700,000. Diagnosis: Pernicious anemia; focal infection nose and teeth.

CASE V. H. M. Age 62 years; occupation, bookkeeper. Family history, negative. Past history, hay fever every year. About March, 1921, patient noticed numbness and tingling of hands. This gradually spread to the distal third of the forearms. Patient says it felt as if he had sand between his fingers. Nine months later numbness began in the lower abdomen and then spread to both lower extremities. For the past year he has had sharp shooting pains which start in toes and fingers. These pains are severe and last about fifteen minutes. Patient has lost about thirty pounds in past six months and feels very weak. About one year ago he had a very sore tongue which persisted for three months. Has had occasional vomiting spells and appetite is poor. Does not complain of abdominal pain. Physical examination: Marked pallor of skin and mucous membranes. Tongue moderately smooth and slightly atrophic; heart, slightly enlarged to left; spleen, not palpable; liver, palpable about 3 cms. below costal margin. Neurological: positive findings; joint sense extremities —3 —4; vibration sense extremities —3 —4. Laboratory: Hemoglobin, 20 per cent; erythrocytes, 1,030,000; leucocytes, 5,600; differential, 100; polymorphonuclear, 36; lymphocytes, 44; large mononuclears, 8; transitional, 10; eosinophile, 2; poikilocytosis, double plus; anisocytosis, double plus; nucleated r. b. c. few. Wassermann, negative. Urine, negative. Diagnosis: Pernicious anemia.

CASE VI. Patient, Dr. F. S. Age 60. History: Present complaint, weakness and pallor. Past history essentially negative. Patient operated March 4, 1919, for acute intestinal obstruction. Onset of present illness two years ago, at which time the patient became tired and weak and drowsy. This feeling of weakness has been gradually increasing up to the present time. During the past month he has noticed a change of color of the skin, an increasing yellowness. He has lost five pounds in weight the past month; headache for the past month. Eyes, ears, nose and throat negative. One year ago the patient had soreness of the mouth lasting about two weeks but there is no history of soreness of the tongue. Gastro-intestinal: Appetite has been poor; nausea but no vomiting. No jaundice; no colic; bowels have been rather constipated. Sweet things make the patient sick. Cardio-respiratory: No dyspnea; feet have been swollen past ten days. Lungs, negative. Extremities: numbness of legs past two weeks. Physical: Marked pallor of mucous membranes and lemon-yellow color of skin; heart slightly enlarged to left; edema; extremities —2 on 1, 2, 3 basis. Spleen not palpable. Neurological: knee jerks, right and left —3 —4 on 1, 2, 3, 4 basis. Achilles, —4 right and left; joint —2 —3 extremities. Vibration, —3 extremities. Laboratory findings; urine showed a slight trace of albumin; otherwise negative; blood, 6-9-23,

hemoglobin, 35 per cent; r. b. c., 1,100,000; w. b. c., 6,600; marked poikilocytosis and achromia. Moderate shadow forms; anisocytosis and polychromatophilia. Blood pressure, 90/60. Diagnosis: Pernicious anemia.

CASE VII. A. D. Age 56 years. Occupation, painter. Family history: mother died of cancer of stomach. Otherwise negative. Past history: Erysipelas two years ago; hemorrhoids past ten years. No bleeding. Present history: Past eight months numbness and weakness of legs; also developed coldness which extends up to his hips. For past month these symptoms have been much worse. No soreness of tongue. Marked general weakness. Examination: marked pyorrhea; slight pallor of skin and mucous membranes. Definite baldness; slight atrophy of tongue. External and internal hemorrhoids. Neurological: Joint extremities, —3; vibration extremities, —3. Knee jerks, right, plus 1 on 1, 2, 3, 4 basis; left, plus 2 on 1, 2, 3, 4 basis. Tactile sensation, —1 to hips. Pain, —1 —2 to hips. Temperature, —1 —2 to hips. Blood: hemoglobin, 75 per cent; red blood cells, 2,370,000; color index, 1.6; leucocytes, 4,600; P. M. N.'s, 62; lymphocytes, 32; large mononuclears, 4; eosinophiles, 2; poikilocytosis, plus; anisocytosis, plus; polychromatophilia, plus. Urine, negative. Gastric analysis: total acidity, 12; free HCl, none; lactic acid, plus; occult blood, plus. Diagnosis: Pernicious anemia; subacute combined sclerosis.

CASE VIII. W. M. Age 57, laborer. Family history: Mother died of tuberculous enteritis at 28. Past history: la grippe 3 years ago; gonorrhea several times; syphilis at 17 with treatment for two months; none since. Present complaint: past ten months patient has complained of tingling in hands and legs with numbness; also progressively increasing weakness. History of sore tongue off and on. Examination: quite marked pallor of skin and mucous membranes. Definite baldness and moderate atrophy of tongue. Pupils, right —2 to light; left, —2 —3 to light on 1, 2, 3, 4 basis; liver edge 3 centimeters below right costal margin. Neurological examination: positive findings: right knee jerk, plus 2; left knee jerk, plus 2; Achilles, right, plus 2; left, plus 2; increased spasticity both legs, plus 2; both sides show Babinski, Oppenheim, Chaddock, Gordon, Mendel, Bechterew and Rossilimo; joint sense right foot, —3; left foot, —2 —3; vibration sense, right foot, —3 —4; left foot, —3 —4; moderate impairment of pain, temperature, tactile sensation both lower extremities. Laboratory examinations: urine negative except slight trace of albumin. Stool negative. Test meal total acidity 8; no free hydrochloric acid. Blood examination: hemoglobin, 24 per cent; red blood count, 1,770,000; leucocytes, 6,750; polymorphonuclear leucocytes, 78; lymphocytes, 19; large mononuclears, 2; transitionals, 1; poikilocytosis, double plus; anisocytosis, double plus. X-ray of stomach and colon negative. Blood Wassermann and spinal fluid negative. Diagnosis: Pernicious anemia. Subacute combined sclerosis.

CASE IX. Mrs. A. W. Age 74, widow. Past history: Negative except father and three sisters had migraine. Past diseases: typhoid at age 15; diphtheria at age 14; migraine attacks up to age 41. Present complaint: patient developed pallor eighteen months ago which has persisted. Tendency to slight sore tongue off and on during this time but lasting only a few days at a time. Has had slight creeping

sensation in hands but no definite numbness since onset of trouble. Has also had an indefinite pulling sensation of the soles of the feet but no numbness. Examination: 1. Lemon yellow tinge to skin with fairly marked pallor of mucous membranes. 2. Tongue shows areas of partial baldness. No definite atrophy. 3. Diffuse slightly elevated areas of brownish color over chest and upper abdomen and arms (*Tinea versicolor*). 4. Blowing systolic murmur over precordium transmitted to axilla. Heart normal in size. Neurological examination negative. Laboratory findings: Urine negative except slight trace of albumin. Blood: hemoglobin, 45 per cent; red blood count, 1,500,000; leucocytes, 3,600; polymorphonuclear leucocytes, 84; lymphocytes, 16; achromia, moderate; marked anisocytosis; marked poikilocytosis. Gastric analysis: total acidity, 6; free HCl, none. Diagnosis: 1. Pernicious anemia; 2. Mitral insufficiency; 3. *Tinea versicolor*.

CASE X. Mr. W. S. Age 34; single; occupation, clerk. Family history: negative. Past history: typhoid at 12; tonsillitis two years ago. Present complaint: patient has developed progressively increasing pallor and weakness past four months. No history of bleeding. Has also been troubled with sore tongue much of this time. Only slight loss of weight. No gastric disturbances. Examination: Lemon yellow tinge to skin with pallor of mucous membranes; diseased tonsils; marked baldness of tongue with slight atrophy; palpable spleen; right inguinal hernia. Neurological, negative. Laboratory findings: urine negative. Blood: hemoglobin, 52 per cent; red blood count, 2,300,000; leucocytes, 4,800; differential, negative; moderate anisocytosis; moderate poikilocytosis; occasional nucleated red. Blood Wassermann, negative. Gastric analysis: total acidity, 10; free HCl, none. Diagnosis: 1. Pernicious anemia; 2. Right inguinal hernia.

Of the secondary anemias, we have unfortunately not run across one with an exceedingly low hemoglobin.

CASE I. R. S. Age 33; single; occupation, laborer. Family history: negative. Past history: negative. Present complaint: past year the patient has had a persistent, indefinite dull pain slightly to the right of the navel. No radiation of pain. This pain has not been influenced by food but is somewhat worse when constipated and after exercise. No urinary symptoms. On two occasions, three months ago and two weeks ago, patient developed profuse bloody stools, bright red in color, and extending over several days. No definite abdominal pain with these spells. Following this a fairly marked pallor developed which has persisted. Examination: Marked pallor of skin and mucous membranes. Moderate tenderness over McBurney's. Urine, negative. Stools (3) negative for occult blood; x-ray of stomach and colon negative; proctoscopic negative. Blood hemoglobin, 40 per cent; r. b. c., 3,504,000; leucocytes, 5,700; differential, negative; moderate poikilocytosis and anisocytosis. Gastric analysis: negative in all respects. Free HCl, 22. Diagnosis: 1. Secondary anemia following hemorrhage from bowel of indeterminate origin; 2. Chronic appendicitis. At operation a chronically diseased appendix was removed. The bowel did not show any other pathology. The gallbladder was negative. The stomach showed a small duodenal ulcer.

CASE II. Mrs. J. S. Age 21. Family history: Mother has migraine; one sister has always looked pale (never had blood tested, however). Past history: Appendectomy two years ago; chorea when nine years of age. Present complaint: Since three years of age patient has been subject to attacks of abdominal cramps in lower middle abdomen, coming at times as often as several times a year and again not for few years. These spells last about six hours and are associated with diarrhea, there being eight to twelve movements during each attack. No pus or blood has been observed in the stools. Was operated on two years ago, elsewhere, following a spell and the appendix was removed. No spells past six months. The patient has always been somewhat pale but especially since birth of last child. Past week patient has had twitchings of right arms and right leg and has been depressed, restless and has given expression to suicidal impulses. Also moderate weakness. No history of numbness, no paresthesias, no definite history of sore tongue. Examination: fairly marked pallor of skin and mucous membranes. Several abscessed teeth; diseased tonsils; palpable spleen; three examinations for blood and parasites were negative; x rays of colon and sinuses were negative. Spinal fluid and blood Wassermann were negative. Gastric analysis was negative throughout. Hemoglobin, 57 per cent; r. b. c., 3,700,000; white blood cells, 7,400; lymphocytes, 16; transitional, 2; p. m. n., 77; polymorphonuclear eosinophiles, 1; basophiles, 1; moderate anisocytosis; marked achromophilia. The patient was on forced nourishment, tonics, and a tonsillectomy and extraction of several teeth were done. Marked improvement followed the latter two procedures, the hemoglobin being 75 per cent on discharge. Diagnosis: 1. Chorea (Sydenham's); 2. Secondary anemia (infectious in origin); 3. Diseased tonsils; 4. Abscessed teeth; 5. Acute recurring enteritis (probably infectious in origin).

CASE III. C. F. S. Age 66 years. Family history: one brother died of diabetes at 70. Previous diseases: rheumatic fever fifteen years ago; several attacks. Influenza twenty-five years ago; four attacks. Present illness: Patient has always been obstinately constipated. He has also experienced a moderate degree of dyspnea for years, as well as a tendency to weakness. His health has been good otherwise up to one year ago, since when all the symptoms have been more marked. The weakness especially has been getting more progressively marked this last year, together with an increasing pallor. With the spells of constipation there is a tendency for the patient to develop vague chest pains as well as pains in the muscles of the hack and a feeling of oppression over the heart. There has also been a tendency to feel depressed. There has been no history of sore tongue nor diarrhea. No numbness or paresthesias; and also no history of bleeding. For the last two years there has been a steadily increasing difficulty in walking; a block greatly exhausts him; after slight exertion feels as if the limbs would not support the body. Physical examination: the color is of a muddy pallor. No definite lemon-yellow tinge. Slight cyanosis of the lips, mucous membranes pale. Radial vessels moderately hardened but no definite calcareous deposits. Heart measure, right, 2.5 cm., left, 11.5 cm. There is a blowing systolic murmur at the apex transmitted to the axilla. There is also a soft blowing systolic

murmur at the aortic area; the aortic second sound is slightly accentuated. Spleen not palpable. Rectal examination showed moderate external and internal hemorrhoids. Blood pressure, 167-78. Laboratory: Hemoglobin, 54 per cent; r. b. c., 3,600,000; w. b. c., 6,400; moderate achromia. Marked anisocytosis; moderate poikilocytosis; moderate polychromatophilia; blood urea showed 22 mg. per 100 c.c. Blood sugar, .169 per cent. Metabolism, —5. Deep and superficial reflexes normal aside from a questionable Babinski in left foot. Vibratory sense diminished in both lower extremities, more marked in left than right. Tactile sense diminished in both feet to the ankle. Diagnosis: 1, Secondary anemia; 2, Moderate arteriosclerosis; 3, Hypertension; 4, Mitral insufficiency with slight cardiac enlargement to the left; 5, External and internal hemorrhoids.

CASE IV. Miss A. B. Age 48. History of flowing off and on for last six weeks between periods. Latter have been profuse past year. Progressively increasing weakness. Examination: Fairly marked pallor of skin and mucous membranes. Uterus enlarged to size of three months' pregnancy. Hemoglobin, 37 per cent; r. b. c., 2,900,000; marked anisocytosis and poikilocytosis and moderate polychromatophilia. Diagnosis: 1, Fibroid uterus; 2, Secondary anemia.

CASE V. Mr. E. E. Married. Age 55. Patient gives a history of tarry stools occurring over a period of several days in March, 1923. This recurred three weeks ago. Patient has had an indefinite distress in epigastric region for the past month not amounting to actual pain. Slight amount of gas; no vomiting. Progressively increasing weakness past month and loss of about eight to ten pounds. Examination: Pallor of skin and mucous membranes; fairly marked. Heart slightly enlarged to left; moderate external and internal hemorrhoids (no bleeding); deformity of duodenal bulb; no retention in stomach. Hemoglobin, 46 per cent; r. b. c., 3,000,000; w. b. c., 7,800; marked anisocytosis and poikilocytosis. Free HCl 3. Gastric analysis otherwise negative. A diagnosis of probable duodenal ulcer and secondary anemia was made and the patient explored. At operation the pancreas was found to be about three times its natural size, fairly hard and impinging on the duodenum, causing the above deformity. The gallbladder, which was thick-walled and bound down by adhesions, as well as a moderately diseased appendix, was removed. It was the opinion of the surgeon that the pancreatic condition was that of a chronic pancreatitis. Subsequent examination—about two months later—showed the patient much improved with a hemoglobin of 75 per cent and red blood count of 4,400,000.

CASE VI. Mr. J. S. Age 54. Occupation, miner. Married. Family history: Mother died at 55, heart disease. Past history: pneumonia. Present history: past eight months epigastric distress daily, coming on right after eating. Previous to this had had epigastric distress off and on one to two hours after meals with food relief. With distress now has gas and bloating. No vomiting. Loss of fifteen pounds in weight with increasing weakness and pallor. Examination: Moderate pallor of skin and mucous membranes. Mass in epigastric region; diseased tonsils; one abscessed tooth. Laboratory findings: urine negative. Gastric analysis: total acidity, 67; free HCl, none. Wassermann, negative. Blood: hemoglobin, 56 per cent;

r. b. c., 2,400,000; leucocytes, 5,600; differential, negative. X-ray of stomach showed marked filling defect of pyloric end of stomach. Diagnosis: 1, Cancer of stomach (inoperable); 2, Secondary anemia.

CASE VII. W. P. Age 65 years. Family history, negative. Past history: Rheumatic fever every year past four years. Present complaint: past three weeks patient has had generalized swelling of joints. Practically all large joints moderately swollen, with stiffness, slight redness and considerable pain. Temperature up to 102. No sore throat. Patient has been rather pale the past year. No history of bleeding. Examination: Moderate swelling of right knee and left wrist with limitation of movement and slight redness. Moderate pallor of skin and mucous membranes. Laboratory findings: Urine negative. Blood: hemoglobin, 55 per cent; r. b. c., 3,050,000; w. b. c., 13,000; p. m. n., 49 per cent; lymphocytes, 48 per cent; eosinophiles, 1; slight poikilocytosis and anisocytosis; basophiles, 2. Diagnosis: 1, Acute polyarthritis; 2, Secondary anemia.

CASE VIII. Mrs. G. L. Age 34. Married. This patient gives a history of impaired health the past two years, manifesting itself chiefly as weakness and anorexia. During this time she has had spells of indefinite fever, the temperature going up to 103 towards the end of the day for a period of several weeks. At these times the weakness is much more pronounced and she is confined to bed. With one of these spells there was an associated attack of abdominal pain and her appendix was removed elsewhere. There is no history of diarrhea; no cough, etc. On examination the following findings were found: marked pallor of skin and mucous membranes. Nine abscessed teeth. Diseased tonsils; moderate abdominal distension and generalized tenderness. Blood count: Hemoglobin, 58 per cent; r. b. c., 3,460,000; w. b. c., 4,400; lymphocytes, 38 per cent; large mononuclears, 3 per cent; p. m. n., 59 per cent. Moderate anisocytosis and poikilocytosis. Examinations such as blood Wassermann, x-ray of chest, investigation for plasmodia, daily four-hour temperature and pulse rate over a week, etc., were negative. Diagnosis: 1, Secondary anemia of septic origin; 2, Alveolar abscesses; 3, Diseased tonsils. The patient was put to bed; extraction of teeth and tonsillectomy were done. She gradually improved on tonics and forced nourishment and when discharged the hemoglobin was 76 per cent.

CASE IX. Mrs. J. S. Age 34; married. Occupation, housewife. Family history, negative. Past history: pneumonia four years ago; influenza two years ago. Present complaint: bloody stools off and on past few years. Up to four months ago, only occasional spells when bright red blood in stools. Past four months small amount of blood in stools practically daily. General health fairly good except somewhat weak. Examination: Moderate pallor of skin and mucous membranes. External and internal hemorrhoids. Laboratory findings: Blood: Hemoglobin, 46 per cent; r. b. c., 3,200,000; differential count negative; slight anisocytosis and poikilocytosis. Urine, negative. Diagnosis: 1, Internal and external hemorrhoids, bleeding type; 2, Secondary anemia due to bleeding hemorrhoids.

CASE X. Mr. J. C. Age 64; married. Occupation, laborer. Family history: Mother died at 50 of heart trouble; father died at 60 of nephritis. Past illnesses:

none. Present complaint: Past nine months patient has been getting progressively weaker and losing weight—loss of 50 lbs. Developed jaundice at onset of trouble, which has become gradually more marked. Noticed a mass in upper right abdomen which has increased in size. Has had progressively increasing gastric distress as dull pain in epigastric region immediately after eating, with occasional eructations of food. Examination: Marked generalized jaundice; marked pyrrhea; emaciation; pallor of mucous membranes; liver extending 8 cm. below right costal margin, hard and irregular. Laboratory findings: Gastric x-ray shows filling defect at pyloric end of stomach. Blood Wassermann, negative. Urine negative except for trace of albumin. Blood: Hemoglobin, 50 per cent; r. b. c., 4,120,000; leucocytes, 9,400; differential, negative; slight anisocytosis and poikilocytosis. Gastric analysis: total acidity, 8; free HCl, none; blood, positive; Boas-Oppler bacilli present. Diagnosis: Cancer of stomach with metastasis of liver; obstructive jaundice; secondary anemia.

The above cases are sufficiently basic and are certainly representative of the anemias, while at the same time they happily exemplify the specific conditions as to the color of the blood serum and its differential significance. The contrast in color is so marked that one cannot mistake it. The yellow color of the blood serum in pernicious anemia may even show a slight greenish tinge with the yellow. Brockbank states there has been no greenish tint in any of his cases. The straw color of secondary anemia varies from a pale straw to a deep straw, depending upon the degree of anemia present; the color of the serum of normal blood is a pale yellow of deeper tinge than that of secondary anemia but not as deep a yellow as that of pernicious. Occasionally a normal serum may approach the color of pernicious anemia, but after having observed several specimens of the latter, the differentiation is not difficult. Spectroscopically, the serum of primary anemia absorbs almost completely the violet end of the spectrum but Dr. Kvitrud has not been able to demonstrate distinct bands of oxyhemoglobin between the D and E lines of the spectrum, and Prof. Joseph Valasek of the Department of Physics, University of Minnesota, has confirmed his findings. Normal serum absorbs a little of the violet at the extreme end but never as much as pernicious anemia. If the serum of the latter is kept in a sealed tube in a few days it begins to lose its color. Unsealed, change is apparent in 24 hours.

Ten years ago I emphasized the importance of the recognition of the nervous syndrome in pernicious anemia, as an aid in diagnosis. Today I am calling attention to a study of the blood serum in this disease as a positive and more reliable aid in

diagnosis even before recognizable changes become apparent. It also enables one to differentiate the nervous disturbances of primary anemia from those due to other toxic influences. There is a feeling that an intractable disease of this character is hopeless, that palliative measures only are indicated, that a possibility of a discovery of its cause and using appropriate therapy is merely a pious hope—the dream of a visionary. It is well to recall what Sir Francis Bacon says regarding supposedly incurable disease—"A work therefore is wanting upon the cures of reported incurable disease that physicians of eminence and resolution may be encouraged and excited to pursue this matter, as far as the nature of things will permit, since to pronounce incurable is to establish negligence and carelessness, as it were, by law and screen ignorance from reproach."

Biochemistry* has greatly enriched our knowledge of this disease; it has not, however, measurably increased our diagnostic acumen. Humiliating though it be, yet we do not know any more about the etiology and cure of this disease than we did one hundred and one years ago when Combe reported the first case. Those were immortal words with which John Hunter addressed Jenner when he was thinking of investigating vaccination—"Do not think, but try; be patient, be accurate."

To the laboratory, nevertheless, we are to look for the ultimate revelation of the pathogenic factor and a subsequent rational therapy. We must not forget, however, that attractive theories too frequently are like glow-worms; they seem brighter from afar. We should never lose sight of the fact "that the history of progress is the attainment of the supposedly impossible." "Before a discovery can be made," says DaCosta,²⁷ "the scientific imagination of some one must flash into Auroral hues."

CONCLUSIONS

1. The nervous disturbances in pernicious anemia are characteristic and distinctive and are observed in over 80 per cent of the cases. Their presence should always suggest the probable occurrence of this disease.

2. The yellow or greenish yellow color of the blood serum in pernicious anemia is easily recog-

*The blood test of Dr. Shaw-MacKenzie, by means of which he has been able to differentiate cancer of internal organs from other non-cancerous conditions in the majority of cases and in obscure cases to exclude the presence of cancer, is believed to possess great diagnostic possibilities. In a total of 221 serums examined, the method has proved correct in 212 or 95.5 per cent. (Simpson.)

nized by the naked eye and is a positive—one might say with Brockbank—*almost a pathognomonic symptom* of this disease.

3. The blood serum of secondary anemia varies from a pale to a deep straw color and, when contrasted with that of the pernicious type, a failure to distinguish between them is not possible.

4. The color of normal blood serum is a pale yellow, has a deeper tinge than that of the secondary form and while it may occasionally resemble it yet after a little experience differentiation is simple.

5. The absorption bands of oxyhemoglobin, described by Brockbank, as explaining the yellow color of the serum in primary anemia, Dr. Kvitrud has been unable spectroscopically to demonstrate; his observations have been confirmed by Prof. Joseph Valasek, Department of Physics, University of Minnesota.

6. The buttercup yellow in the blood serum of primary anemia is readily seen by the unaided eye. With a little experience the practitioner can, by its observation, make a diagnosis of this disease before definite changes manifest themselves.

7. The blood serum in the border-line cases requires patient research. A later contribution may be expected.

NOTE: I am greatly indebted to Dr. Gilbert Kvitrud, Director of the Laboratory of Mounds Park Sanitarium, for painstaking research, and to Dr. Arthur E. Mark, for his aid in the collection of cases and review of the literature. Without their assistance this paper would not have been written. To Miss Hirsch of the Department of Anatomy, I am indebted for the drawings of the blood serum from the actual specimens, and to my friend, Dr. Frank E. Burch, for the excellent colored slides.

DISCUSSION

DR. GILBERT KVITRUD, St. Paul: Dr. Brockbank says that he finds the absorption bands of oxyhemoglobin in the serums of most of his pernicious anemia patients. I have examined the serums of ten or more primary anemias and have as yet not been able to find distinct bands between

the D and E lines of the spectrum when using an absorption cell 1 cm. thick. The only absorption seen with the two prism indirect spectroscope is at the violet end of the spectrum, the violet being usually completely absorbed.

Drs. Riggs, Mark and myself have studied the serums from a number of pernicious and secondary anemia patients as to color and agree with Dr. Brockbank that these serums have a characteristic pigment. The color of a secondary anemia serum is pale straw, while that of primary anemia is deep yellow and at times a greenish yellow. We do not know what this pigment is or why it should appear in serums of pernicious anemia.

We will have something to say of the border line cases at a future date.

DR. CHARLES R. BALL, St. Paul: Mr. Chairman, Ladies and Gentlemen: I think we should be very grateful to Dr. Riggs for calling our attention to another diagnostic point in the early recognition of pernicious anemia. I confess that in most of the cases which come under my observation a diagnosis from the blood elements alone at the time I see them is very difficult. The blood picture may be suspicious but lacks very much of being pathognomonic.

For many years I have depended, in my recognition of this disease, more on the nervous symptoms than I have on the blood findings. In those cases which manifest nervous symptoms, these seem to be quite pathognomonic of this condition.

Chief among these symptoms is a numbness in the fingers, and on the soles of the feet; the patients complain very much of this numbness and in the use of their hands and fingers are very clumsy. In the female patients, they complain that they are unable longer to sew because they cannot hold a needle.

In the men, they say they are unable to button their clothes and if you ask them to attempt to do this, you see that they are fumbling constantly for the button and the button-holes. The sensation in their finger tips is not sufficient for them to recognize these distinctions.

Also, there is an exquisite sensitiveness, quite general all over the whole body but perhaps best exemplified in the calves of the legs. You can bring this out nicely by pinching the calves.

Then, there is quite a marked disturbance in balance.

In the connection in which these symptoms are found, it is not difficult to differentiate pernicious anemia findings from other disease. I cannot think of any condition which presents quite this syndrome in the background in which it occurs.

Then, the tongue has been quite an important factor in the aid to diagnosis. You all know the characteristic tongue so often seen in pernicious anemia, the rather small atrophic looking tongue which is red and perfectly clean and sometimes sore around the edges. This is a factor which should never be neglected in making a diagnosis.

I used to think that the nervous symptoms were due to the anemic condition in the blood. I have long ago given up this idea.

In my opinion, the nervous findings are due to the same toxic agent which causes the blood changes. Sometimes this toxic agent depresses the blood almost entirely and does very little damage to the nervous elements, while in other cases the situation is exactly reversed. The nervous

elements are the ones which seem to be affected the most and the blood changes are moderate or perhaps none which one is able to recognize.

Two years ago I had two very interesting cases occurring in a man and his wife. The man had a high grade of anemia and very few nervous symptoms. The wife had no blood changes whatever but marked nervous disturbances such as one would expect in a case presenting a combined sclerosis.

These two cases of pernicious anemia occurring in man and wife makes one wonder if there may not be some tendency of an infectious nature in this condition.

If this serum test, which Dr. Riggs has presented to us, proves to be reliable, it will make the early recognition of cases of pernicious anemia much easier than it is at present.

DR. HENRY WOLTMAN, Rochester: It is given to very few men to see their contributions withstand the weathering influences of 27 years. Dr. Riggs was the first in this country to report a case of pernicious anemia with microscopic examination of the central nervous system and we find that his observations stand today as they did then. Prophecy is a dangerous business for the prophet, but here, too, he has succeeded for his assertion that the examination of the nervous system would prove to be a valuable aid in the early diagnosis of pernicious anemia has been amply verified.

Recent evidence has been adduced by Martius, Weinberg, Hurst and others, that goes to show that the achlorhydria, the *sine qua non* of pernicious anemia, is not the result of an atrophy of the gastric mucous membrane, but represents a primary, constitutional, familial deficiency, present from infancy. It is only in these cases, supposedly, that pernicious anemia develops. Grawitz, furthermore, has demonstrated that hemolysis is often lacking, and regards a primary bone marrow deficiency as the important conception. This conception, too, is in line with the suggestion first made by Dr. Riggs, that individual predisposition probably determines which patients are going to develop degenerative changes in their nervous systems.

The clinical changes defied all explanation on the basis of known cord involvement alone, and it was not until Hamilton and Nixon demonstrated the frequency of multiple peripheral nerve degenerations that the problem reached solution. This fine piece of work, and Barrett's demonstration of Lichtheim foci in the brain, are the two outstanding contributions to our knowledge of the pathology of pernicious anemia since Lichtheim's original work.

I am not qualified to discuss the color reactions of the serum as described by Dr. Riggs, save to say that because of its simplicity it should prove to be of the greatest practical value to the general practitioner and hence of the greatest benefit to the patient.

Some years ago Blankenhorn called attention to the marked increase in bile pigments in the serum of pernicious anemia patients and stated that the intensity of the reaction ran parallel to the neurotoxicity exhibited by the case. I should like to ask Dr. Riggs whether the intensity of the color of the serum shows any parallelism to the neurotoxicity?

In 1904, Syllaba called attention to pre-pernicious anemia icterus. Is there any parallelism between the color of the serum and the intensity of the icterus?

There is always a tendency to attribute too much

specificity to a new test. Dr. Riggs warns against this, but may I ask whether this reaction has been observed in any other conditions, such as congenital hemolytic icterus? Possibly not enough cases have as yet been observed to answer this question.

Finally, may I ask about the color of the spinal fluid when this reaction is present?

DR. H. M. CONNER, Rochester: I also should like to ask Dr. Riggs if this color change is any different in pernicious anemia from that which occurs in any of the hemolytic anemias, such as, for instance, in hemolytic jaundice which Dr. Woltman has mentioned; also whether the color can be distinguished from that which occurs in any case of jaundice? Last spring it was my pleasure to talk with Dr. Bernheim, whom Dr. Riggs mentioned, regarding the color changes in the serum. At that time Dr. Bernheim was not able to distinguish between the color changes in jaundice and those occurring in hemolytic anemias. On the face of things, knowing that in the hemolytic anemias we have increased destruction of the red blood cells, it would appear that this color change is due either to the liberated hemoglobin or to the bile pigments formed from the excess hemoglobin. If this is true, one would not be able to make this test a diagnostic feature of pernicious anemia.

DR. C. EUGENE RIGGS (closing): When I was a boy in Sunday School I remember we had a lesson in which angels were spoken of. I asked the teacher, a very distinguished clergyman, if he knew what an angel looked like. He smiled and he said: "I don't, do you?" You understand this is a preliminary note, and these things that my good friend Woltman and the speaker following him emphasized, we have not had time to investigate. We have only had time to go into the simple facts that we have given to you today, and you will remember that I said that other communications might be expected.

I am sorry, but I will have to give you the same answer that the Sunday School teacher gave me, Dr. Woltman, with

reference to the questions you have asked. But we feel that if there is anything in this contention of Brockbank it is an especial boon to the general practitioner. It is something that as medical men we ought to investigate and consider with a critical judgment and reject if we find that our hopes have not been realized.

The last speaker asked with reference to the vibration test. That, of course, we very definitely find in primary anemia. I have forgotten the other question.

THE CHAIRMAN: Sense of posture.

DR. RIGGS: In this little abstract I gave you I could not make any reference to this because of lack of time. I might say that the loss of deep sensibility is the most important differential point from a nervous standpoint. Dr. Kvitrud will explain to you the preparation of this serum. If you get hemolysis it vitiates the diagnosis. I would like to say that these drawings which the doctor has are very much more satisfactory in every way than our slides and they were made by the artist at the University in the Department of Anatomy and taken from the actual laboratory specimens.

DR. GILBERT KVITRUD: Of course, this blood has to be obtained in such a way that there is no hemolysis and in order to do this we use a sterile syringe and rinse it out with a five per cent sterile sodium citrate solution. We obtain 5 c.c. of the blood and inject it into a test tube carefully so that there will be no mechanical hemolysis. Then put the tube in a slanting position so that the serum can separate out better than if the tube was upright. We usually leave it over night and then draw off the serum the next day and centrifuge it for quite a while with a high speed centrifuge. After that, it is ready for the examination by the spectroscope or grossly as to color.

It would be pretty hard to transport the blood. If you went some place to get it you would almost have to leave it there until the serum separated out, and then you could take the serum and centrifuge it when you get to your hospital or office.

SILICA IN TUBERCULOSIS

Compounds of silica have found a place during recent years among drugs of reputed value in the treatment of tuberculosis. In view of their extreme insolubility, one would scarcely expect them to exert any immediate pharmacodynamic effect. Nevertheless, there is evidence that silica finds its way into the tissues and organs and remains deposited, notably in connective tissues. This has given rise to the hypothesis that the element plays a part in determining the elasticity and tensile strength of fibrous tissues, although the smallness of the quantities of silica ordinarily found should make one extremely skeptical of the validity of any conclusion of this sort. Nevertheless, various silica-containing teas or drugs have been recommended in the hope that they would increase the amount or improve the quality of the connective tissue that forms the defense about tuberculous lesions. A study at the Sprague Institute in Chicago by Maver and Wells brought nothing but negative results through the administration of silica preparations to tuberculous animals.—*Jour. A. M. A., May 17, 1924, p. 1610.*

PROMONTA NOT ACCEPTED FOR N. N. R.

Promonta (manufactured by the Chemische Fabrik Promonta G.m.b.H., Hamburg, Germany, and distributed in the United States by the Acme Pharmaceutical Co., Chicago) is said to be "an organic preparation from nervous matter of the central nervous system combined with polyvalent vitamins, lime, iron, hemoglobin and soluble albuminoids." Promonta is reminiscent of the "Nerve, Brain and Skin foods," "nerve tonics," etc., which had their vogue in the United States before the passage of the Food and Drugs Act; like them, it is recommended for "neurasthenia," "all kinds of fatigue and exhaustion," "anemia," "bloodlessness," "impaired vitality," etc. The inclusion of "4 per cent" of "polyvalent vitamins" (source not stated) is a modern touch, as is also the reference to experiments on animals (with pictures) which had been made to grow more rapidly by the addition of "Promonta" to their usual diet. Promonta is an irrational mixture of secret composition exploited under preposterous claims.—*Jour. A. M. A., May 24, 1924, p. 1712.*

OBSERVATIONS ON SOME OF THE MORE
RECENT PROBLEMS IN RHINOLOGY*

G. E. SHAMBAUGH, M.D.

Chicago

The history of medicine gives no more interesting record than that of the various troubles attributed at one time or another to nasal conditions. The rather complicated structure of the nasal cavities, especially those of the ethmoid, and the relation of these cavities and accessory sinuses to important structures such as the orbit, nerve trunks and the brain cavity, all combine to render plausible, or better perhaps, possible, some more or less satisfactory anatomical basis for explaining symptoms attributed to the nose.

The discussion over nasal reflexes which began in 1871 when Voltolini reported two cases of typical bronchial asthma cured by removal of nasal polypi, resulted ten years later in a flood of contributions to the literature discussing the subject of reflex nasal neuroses in which were expressed the wildest prophecies regarding the extent of the nasal relation to other diseases. There were those who seemed ready to believe that there was scarcely any ailment that might not be cured by treating the nose. Many rhinologists of those days accepted the view expressed by Bosworth that all cases of spasmodic asthma are associated with pathological conditions in the nasal cavities and, furthermore, that the source of asthma can always be traced to these nasal conditions. It is quite easy for all of us today to agree with the first of these propositions, namely, that all cases of asthma are associated with palpable evidence of pathological changes in the nasal cavities or sinuses, particularly if we are permitted to include such conditions as the usual irregularities of the septum and the ordinary turgescence of the turbinated bodies. The genuine enthusiast on nasal neuroses did not even stop at palpable evidence of abnormal conditions in the nose, but advocated the existence of hyper-sensitive spots in the mucous membrane of the septum and turbinated bodies in noses, that appeared on inspection quite normal, from which these supposed nasal reflexes might arise.

What was claimed in the eighties regarding the

relation between asthma and the existence of palpable changes in the structure of the nasal cavities, we can all accept regarding such conditions as headache, eye symptoms, various so-called neuralgic syndromes, migraine, and, indeed, any other condition we might care to mention. On the other hand, it is quite another matter to assume that the co-existence of two conditions such as palpable evidence of alterations in the complicated nasal cavities and such symptoms as headache, neuralgia, various eye symptoms, means, therefore, that these nasal conditions are causing the symptoms. In the discussions over asthma there were those who assumed that this condition was always dependent on some alteration in the nose, the correction of which would cure the asthma. This was clearly but one way of stating that the relief from asthma was dependent on the skill displayed by the rhinologist in his efforts to discover and to eradicate the causative nasal conditions, many of which appear to most of us more imaginary than real. It is at once apparent that such an attitude places the treatment of asthma in a most unsatisfactory state since it must inevitably lead to a great deal of misdirected, uncalled-for surgery.

The conscientious rhinologist who has a proper feeling for the responsibility which should be his of guarding the field of medicine for which he is sponsor, cannot but deprecate a teaching which leaves open a portal for indiscriminate surgery. This responsibility falls the more heavily on the properly qualified rhinologist today because this special field has, in recent years, been flooded by men who, after a few weeks' or months' attendance at clinics in our cities, have taken to operating on the nose and throat without any of the more important and much more difficult training for making careful examinations and for determining proper indications for surgical interference. In recent years I am encountering an increasing number of patients who have been subjected to unnecessary operations, usually upon the ethmoid and sphenoid sinuses, where we find no reason for believing that pathology had existed in these regions, cases operated for the relief of such conditions as typical, hereditary migraine and eye or ear symptoms which it would seem no stretch of the imagination should rationally connect with nasal sinus trouble.

It is always important to remember that reasoning post hoc, propter hoc, is often very misleading.

*Presented before the Minnesota Academy of Ophthalmology and Oto-Laryngology, St. Paul, Jan. 17, 1924.

It is just this sort of reasoning that supports osteopathic or chiropractic treatments or the wearing of the hind foot of a rabbit for the cure of rheumatism. To illustrate—because a patient suffering from a mild attack of acute catarrhal otitis media complicated by a facial paralysis which latter disappears in due time after the mastoid has been extirpated is no proof that the operation on the mastoid had any beneficial effect, for, as we all know, such cases of facial paralysis usually clear up spontaneously quite promptly on the subsidence of the catarrhal otitis media.

Let us inquire into some of the questions which have more recently been raised in rhinology. One of the first of these is the so-called vacuum headaches attributed usually to the frontal sinuses. The frequent rather narrow passage from this sinus into the nose, particularly when the naso-frontal duct opens into the anterior end of the infundibulum, makes the closure of this passage from acute swelling of the mucous membrane a rather simple matter. It is assumed that the closure of this duct takes place and is followed by the creation of a vacuum in the sinus and the development of pain over the sinus from negative pressure without inflammation of the membranes lining the sinus and without the accumulation of fluid in the sinus. How such headaches are made persistent because of chronic hyperplastic changes in the underlying bone, particularly of the unciform, has all been elaborated with great detail. The occurrence of such vacuum headaches cannot be very common since I have never been satisfied that I have encountered a case where the hypothesis of a vacuum within the sinus offered the most plausible explanation. What shall we say regarding the occurrence of the type of headache attributed to vacuum formation with the so-called sensitive Ewing's point over the orbital wall and where the skiagraph demonstrates the complete absence of any frontal sinus?

There is another question which I have found difficult to answer if we accept the vacuum hypothesis for frontal headache, and that is the failure to find these headaches in cases of advanced hyperplastic ethmoiditis where the development of polypi completely closes the middle meatus. It would appear that in just these cases where we are most certain of the closure of the naso-frontal duct the vacuum headache must be the rule. As a matter of fact, I have never found headache of any

type a frequent symptom of this condition. It is just cases such as these that question the validity of the whole theory of vacuum headaches. It would seem, moreover, from analogy with the obstruction to the Eustachian tube that the sinus would soon fill with a serous exudate, not a condition which in itself causes pain for it would not be a fluid under pressure, but a condition which would very quickly relieve any negative pressure. Sinus disease in which there is accumulation of inflammatory exudate within the sinus is a common symptom of sinusitis particularly when there exists an obstruction of the ostium. On the other hand, the occurrence of headaches independent of any palpable sinus disease is very much more common.

Some very interesting observations have been made on the relief of certain types of headaches by the application of cocaine or other analgesic agents, for example, to the region of the sphenopalatine ganglion. This phenomenon has been taken as an indication of the manner through which inflammatory disease of the nasal cavities produces involvement of the nerve trunk either by extension of toxins or of the inflammatory reaction through the bone or as the result of hyperplastic changes in the bone presumably setting up neuralgia through pressure on the nerve trunks. The fact that cocaine passes through the nasal membranes and affects the nerve trunk or ganglion is no reason for attributing the same penetrating faculty to the products of inflammation. In support of this hypothesis for the local cause of these neuralgias, the great frequency with which the membranes of the nose become the seat of acute inflammatory attacks is pointed out. In addition, an effort has been made to associate certain chronic, rather impalpable alterations in the nasal mucous membranes with the etiology of these neuralgias on the theory that these alterations in the nasal mucosa indicate hyperplastic changes in the underlying bone which in turn effects an injury to the nerve trunk. All of this is very interesting and while it is perhaps not easy to disprove, we must all admit that it is even more difficult to prove.

I have recently been studying a case with the typical sphenopalatine neuralgia syndrome and where an application to the region of this ganglion just back of the posterior tip of the middle turbinate body is quickly followed by a cessation of the pain. The patient has perfectly normal nasal

passages so far as I have been able to discern, nor is she in any way particularly susceptible to attacks of acute rhinitis. Now are we to assume that there is some often quite impalpable local change going on in the nose in such cases that extends to and involves the nerves? Why is it not more probable that the cause of the sphenopalatine neuralgia is the same as the more usual cause of neuralgia occurring elsewhere, not a local cause at all, but some focus of infection, placed at a distance from the nerve affected? Such an explanation would seem more logical than to assume a purely local cause acting in a manner quite unique for these particular nerve trunks.

All of these conclusions have a bearing on the problem of handling such cases. If neuralgias of the sphenopalatine are the result of the same cause as a neuralgia elsewhere then our first aim should be to search out and eradicate any existing focus of infection and resort to the local treatment of the ganglion only when the neuralgia is not relieved by these other measures which aim to eradicate the original cause.

When we add to these pain syndromes from the nerves occupying the bony wall of the nose the question of the involvement of the optic nerve because of its proximity to sphenoid and posterior ethmoid cells, the rhinologist is indeed confronted by a serious and difficult problem. In the first place, the ophthalmologists assert that they are not capable of telling just what cases of nerve involvement are caused by extension of sinus disease. On the other hand, the competent rhinologist is rarely left in doubt about the diagnosis of a sinus disease where this is associated with a suppurative process. But we are confronted by the proposition that the sinus disease may be a hyperplastic non-secreting disease of which the skiagraph gives no clue and for which neither anterior nor posterior rhinoscopy can give us any tangible evidence, unless, perchance, we use a peculiarly brilliant light and even then the evidence is so impalpable that few will be able to recognize the trouble.

These propositions demand the most serious consideration from the rhinologist for if they are entirely correct then it certainly is incumbent on the rhinologist in most of such cases, at least of optic nerve involvement, to operate on the posterior ethmoid and the sphenoid. The operation must be undertaken not only in those cases where a suppuration in these cells can be diagnosed, but even when

an absence of a suppurative process can be reasonably assured. This is, to say the least, not a very satisfactory position for rhinology. It is very much the same position in which rhinology found itself in the discussion over nasal reflexes in the eighties, for it opens the way, as did those discussions, to rather indiscriminate intranasal operations, with this exception, that the operations on the posterior ethmoid and sphenoid are much more formidable undertakings than the proposal for the relief of nasal reflex neuroses.

Let us inquire into some of the questions that arise in this problem of optic nerve involvement. In the first place, it is evident from the frequently demonstrated proximity of the optic nerve to the posterior ethmoid and sphenoid sinuses that inflammatory diseases of these cells might extend to injure the nerve. Do we not have an analogous situation when an involvement of the facial nerve develops in association with an otitis media? In the case of the facial nerve, it is apparently as often the extremely mild acute catarrhal process as it is the more severe suppurative disease that produces facial paralysis. Moreover, it is the acute processes that affect the nerve. Facial paralysis is never the result of the chronic, hyperplastic adhesive middle ear catarrhs nor is it often the result of chronic suppurative otitis media even where the hyperplastic changes in the mucosa and underlying bone are more conspicuous. Where it develops in chronic suppurative otitis media, it is usually the result of erosion of the canal walls by cholesteatoma or it is the result of sequestrum formation.

How these facts affect the problem of optic nerve involvement of nasal origin is quite obvious. Such involvement should be expected usually in connection with acute processes and not necessarily either the more severe processes. We should hardly expect nerve involvement from any chronic non-secreting hyperplastic process nor should we expect it to develop in the severe chronic suppurative process unless these conditions are associated with severe persisting headache indicating either retention or necrosis. The absence of nerve involvement in association with the chronic hyperplastic nasal process is quite in keeping with what we know of the bony changes in such processes. Beginning with the contribution of the English rhinologist, Woaks, attention has been directed to the bone changes in hyperplastic ethmoiditis. That such bone changes differ in any way from those that

result from periostitis in any other locality has not appeared. That these hyperplastic bone changes take place on the nasal aspect of bony walls cannot be taken as proof that similar changes occur on the opposite side of the bone, that is, on the orbital wall or the inner aspect of nerve channels. This is a problem still to be worked out.

When an optic neuritis occurs in connection with an acute sinusitis involving the sphenoid and possibly the posterior ethmoid is it desirable to subject all of these cases immediately to operative treatment? It has been urged in support of this procedure that some cases of optic neuritis proceed to recovery after the operation on the sinuses. But who can assure us that the improvement does not result in spite of the operation rather than because of this work? Do not many of these cases recover spontaneously on the subsidence of the acute sinusitis exactly as do most cases of facial paralysis that complicate the mild attacks of acute otitis media and that without any mastoid operation? Again, is not the recovery of the optic neuritis that occurs after an operation for draining the posterior ethmoid and sphenoid where we have clinical evidence of only a mild type of acute sinusitis quite analogous to the recovery of the facial paralysis in the mildest form of acute otitis media after there has been performed a quite unnecessary operation on the mastoid?

Gentlemen, I feel that all of these are pertinent questions which we should think over when we are confronted with a case of optic neuritis associated with an acute sinusitis.

In general, the logical conclusion would seem to be in acute cases of sphenoid sinusitis, the decision to operate should be made only after looking into the degree of nerve involvement on the one hand and the severity of the sinusitis on the other. Where either of these factors is severe, operate at once. When both are mild, do not be too hasty about operating since the probability is that there will be a spontaneous recovery in the course of a few weeks. When such recovery is not forthcoming, especially when there is a persistence of the sinusitis, the question of recommending the operation should be again seriously considered.

Now we come to one of the most serious of all the problems in connection with this question of optic neuritis and the occurrence of sinusitis. The ophthalmologist diagnoses a case of optic nerve involvement, the patient is referred to the rhinolo-

gist, who is unable to discover any palpable evidence of sinusitis or ethmoiditis. In spite of this negative finding, he is asked to operate on these sinuses because it may not be possible in all cases to positively exclude the occurrence of posterior ethmoid or sphenoid involvement. As proof that there existed an undiagnosed, undiagnosable sphenoid-ethmoid condition responsible for the eye trouble, it is pointed out that in some of these cases the optic nerve trouble subsides in time after the operation on the sinuses. But the matter is not so simple as all this, for in other cases in spite of the most radical operative measures, no improvement in the nerve takes place. Who shall say but that in those cases where improvement has followed an operation when no sinus disease could be discovered this improvement has not been in spite of rather than because of the operation.

There is another thought that arises in just such cases where the rhinologist finds no evidence of sinus disease. An acute involvement of the optic nerve even when this develops in the wake of an acute rhinitis, is no proof that such involvement occurs as the result of direct extension of inflammation or infection through the sinus walls. Only last week I had the opportunity of studying two cases, both occurring in young adult life, of acute neuritis of the eighth nerve. In one there was the history of a mild attack of coryza preceding the nerve involvement; in the other the only cause given by the patient was that she went out in the cold too soon after giving her head a shampoo. In both of these patients there was distinct evidence of focal infection both in the teeth and in the tonsils and the logical conclusion seemed to be that the latter was the important etiological factor in the development of the neuritis of the eighth nerve. The question naturally presents itself in acute optic neuritis when the etiological factor is obscure, even when the process is associated with an acute head cold but without palpable evidence of a sinusitis, may not focal infection be the important etiological factor? To my mind the two situations are quite analogous and it does not seem entirely logical to assume the existence of some impalpable, undiagnosable sinus condition as causing the optic neuritis when another explanation entirely different has to be assumed for the other. It has seemed to me that the importance of focal infection in the causation both of headaches, the sphenopalatine neuralgia, as well as of the involvement of the optic nerve

has been overlooked and that in the efforts to fix upon both of these conditions an etiology primarily rhinological, there has been a resort to hypotheses which are not only unproved, but are essentially unprovable, although one may not be able to disprove them.

These more recent problems that have come into the field of rhinology even though they may all eventually be put aside as having no great value have nevertheless already served a good purpose in stimulating a greater interest in rhinological work and have demonstrated in a most forceful manner the necessity of providing opportunity where men seeking preparation may be able to get something more than a smattering of operative technic while neglecting the more difficult and more important training in examination and diagnosis.

The conscientious rhinologist will guard with scrupulous jealousy the work in the field for which he is sponsor. He is not only anxious to avoid the risk of indiscriminate, unnecessary surgical work, but he is equally anxious to make sure that everything that is possible is being done for his patient. When such a serious condition exists as the loss of vision through an optic neuritis, the decision whether or not to operate should be reached only after consultation with the ophthalmologist, and, I might add, he should be ready to carry out any reasonable operative procedure even though he may be in doubt as regards the existence of a nasal cause.

NUGA-TONE

This is a nostrum sold on the mail order plan by a concern in Chicago called the "National Laboratory"—the latest name under which one Charles E. Cessna carries on mail order quackery. Nuga-Tone is described as the "Great Nerve and Blood Builder." It has been advertised in that class of weeklies sometimes described as the "cheap and nasty." The advertising does not tell just what is in Nuga-Tone. It does say that it is "rich" in iron and phosphorus, and also contains cascara and "nux." Further, one is told, "there are four other medicines" in Nuga-Tone. The death of a boy, three and a half years old, who had taken Nuga-Tone tablets in his parents' absence, is reported. When the death was brought to the attention of the National Laboratory, a formula was furnished which showed that each tablet contained 1/60 grain of mercuric chlorid, 1/60 grain of strychnin sulphate and 1/40 grain of arsenic trioxid. There is no law in this country which prohibits the indiscriminate sale of such dangerous nostrums. — *Jour. A. M. A., May 17, 1924, p. 1628.*

THE THIEF IN THE NIGHT—NON-INFLAMMATORY GLAUCOMA

W. W. LEWIS, M.D., F.A.C.S.

Saint Paul

Stealthily creeping in, without outward visible sign or warning, to rob us of our most treasured sense, is the picture in his mind's eye, ever to keep before him, that every practitioner of medicine should have of simple, non-inflammatory glaucoma, for no more tragic affliction is the lot of man. Generally, one might say most frequently, unrecognized until well advanced, the most precious time for its combatment is only too often used up by the optometrist, and others untrained in ocular pathology and clinical ophthalmology, in repeated change of glasses—given with the opinion that the patient "is becoming far-sighted" or that "it may be an oncoming cataract," et cetera. And finally, only too late for help and after optic nerve atrophy is well on its way, the patient consults the oculist, whose sad and painful duty it becomes to tell that nothing can be done; and the unfortunate person must drift into the long night of blindness.

"Early recognition means everything. Late recognition or wrong diagnosis means loss of everything" (Fuchs). Although primary glaucoma, according to Fuchs, constitutes 1 per cent of all eye diseases, how extremely infrequently the general practitioner recognizes it or even suspects it only the well-occupied oculist is conscious of, and this, too, in cases of the inflammatory form. Iritis and iridocyclitis, in the presence of an inflamed eye, seem almost always thought of, and that diagnosis is generally made in most cases even if the patient is fortunate enough to be spared the catastrophe of having atropin put in his eye. How much more rarely, then, the non-inflammatory form, without a single outward objective sign, is even suspected, can well be imagined. Just such cases are the ones which, during the very time that something could be done for them to halt the dreadful malady, are glassed and reglassed by the optometrist and others without special training, only to lose steadily the remaining vision they possess. These cases, too, as we all know and are sad in the realization, go undiagnosed through the hands of careless and superficially working oculists,—the kind of refractionists who are satisfied with less

than normal vision in their patient without finding the reason why; who pass over accommodation inability in their patient without the compatibility of age or hyperopia; who are in too much of a hurry to take the field of vision when it is indicated; and whose dark-room observation is less than a careful, thorough, and searching examination of the anterior segment of the eye by oblique illumination and loupe, and the posterior segment of the eye (including lens, media, peripheral retina, macula and nerve-head, its color, size, margins, elevation, cupping and vessels and their behavior) with ophthalmoscope. Just such work has belittled scientific refraction, than which no branch of ophthalmology is capable of requiring more high training, good balance and sound judgment; this type of man's refraction takes no longer to do than the optometrist's, and in reality is not worth any more, and is responsible now for the growth and prominence of the optometrist and his kind in our midst.

A fact all oculists must ever impress upon themselves is that glaucomatous cupping with atrophy is too late for help. Cupping prior to atrophy is what we strive to find and it is our business to recognize it.

There are three types of cupping of the nerve-head: (1) physiologic; (2) atrophic (ordinary optic nerve atrophy); (3) glaucomatous.

Physiologic cupping is partial cupping, never total cupping of the entire breadth of nerve-head, nor deeper than the lamina cribrosa in its normal location. Any depth of the physiologic cup is due to its depth in the plump, heaped-up nerve-fibers, and the vessels do not emerge at the margin of the disc. The lamina cribrosa may be seen at the apex of the funnel but not across the whole width of disc at the floor of the cupping. On the other hand a total cupping of the entire breadth of nerve-head from margin to margin is always pathologic and must be either atrophic cupping or glaucomatous cupping.

The cupping of atrophy of the optic nerve, or so-called atrophy cupping, is a shallow, flat, white-bleached cupping never deeper than the lamina cribrosa in its normal location, and the atrophy is present before the cupping takes place; in fact, the shrinking or atrophy of the nerve-fibers makes all the cupping there is, with fenestrae of the lamina cribrosa exposed as a result of shrinkage.

The cupping of glaucoma, rather shallow at

first, is deeper than the normal location of the lamina cribrosa; is caused by its recession under intra-ocular pressure; and is there before atrophy of the nerve-fibers takes place; in fact, the after-coming shrinkage of nerve-fibers in the already existing cupping adds considerably to its depth. It is just at this stage where we as oculists should be on the job; that is, recognize the cupping (recession of the lamina cribrosa) before atrophy takes place and while the nerve-head is yet a healthy pink and the fibers plump; before the blue-green color appears and before the shrinkage adds to the depth of the already existing excavation and the exposure of fenestrae of the lamina cribrosa. After these are present it is too late for help. At this stage, before the healthy pink color fades and before the lamina cribrosa fenestrae are exposed by shrinkage, the proximity of the vessels to the very edge of the disc should immediately put us on our guard. Later the characteristic bending over and disappearance of vessels at the edge takes place, but this is generally found after the added depth of the excavation results from shrinkage.

Even in the presence of a well-defined glaucomatous change in the nerve-head in a hurried, superficial inspection, especially by indirect ophthalmoscopy, it is very easy to miss the telltale behavior of the vessels, which, reappearing at the bottom of the excavation, upon close examination, can be seen to have a different hue, and by paralactic displacement can be seen to be at a marked difference in depth. This, I repeat, can be easily missed except in detailed inspection by direct ophthalmoscopy, especially while the nerve-head is still pink in health and before atrophy has arrived.

Contracted arteries and slightly distended tortuous veins should immediately arrest the attention of the observer, for at this stage the recession of the lamina, prior to atrophy, does not include as yet a decrease in vision, and the time is even here at hand, by proper medical and surgical relief, to arrest and avert the atrophy which does mean loss of vision. Even in the presence of large, unmistakable pathologic cupping good vision and uncontracted fields may be found.

Of course the exception to this can be found in acute fulminating inflammatory glaucoma, where the pressure comes on so suddenly and acutely that destruction of life in the nerve-fibers takes place even before the lamina has had time to yield and recede. In this form of disease very often, if not

too prolonged, considerable recovery of vision may be found, but that it has suffered can be demonstrated in careful field-taking, by the presence of sectors or gaps reaching even to the macula or normal blind spot.

Ordinarily, then, estimation of glaucomatous damage can best be made not by the excavation but by the color of disc (pink color of health or gray-white of atrophy) and by the size of the arteries. The classic halo around the excavation is due to sclerosis and pressure-atrophy of the choroid; but this, of course, is a late, too late, finding.

Glaucoma—that is, inflammatory glaucoma—has been known from antiquity, and all the old writers have associated it or thought of it in connection with gout and arteriosclerosis. Simple, or non-inflammatory glaucoma, was never known or thought of in connection with the known (inflammatory) glaucoma until the advent of and since the progress of our knowledge from the use of the ophthalmoscope. Mueller first demonstrated glaucoma cupping anatomically in 1856.

Intra-ocular pressure and tension were first associated with glaucoma by Mackenzie and by von Graefe. Mackenzie relieved it by repeated paracentesis, but without permanent result. Von Graefe discovered, merely by coincidence, that iridectomy relieved it and in most cases with permanently good result, and this discovery proved to be one of the greatest advents in the history of ophthalmology. Von Graefe's declaration that the "essence of glaucoma lies in the increase of intra-ocular tension, from which all symptoms can be deduced," really stands unchallenged today and is the universally accepted idea of glaucoma.

Two chief divisions of glaucoma are: (1) primary and (2) secondary. Primary glaucoma comes on without any known antecedent disease. In this group are the inflammatory and the non-inflammatory affecting both eyes, generally one after the other in its start, but ultimately both. This class is the real glaucoma or the pure glaucoma. Secondary glaucoma is really merely a complication of tension in an already diseased or injured eye, resulting from the interference of exit of the intra-ocular fluids from the eye, and affecting only the eye in which the pre-existing disease or injury is present. It is merely an accessory and would not have come on except as a result of

such disease or injury. Secondary glaucoma is, of necessity, mostly an inflammatory glaucoma.

The common conception of the entrance of the optic nerve as through a round hole or opening in the sclera is entirely incompatible with a correct understanding of the pathology of glaucoma. There is not a gross gap or gross opening in the sclera at the point of entrance of the optic nerve. The scleral fibers are merely pushed aside like the slats of lattice work, offering a multiplicity of minute fenestrae through which the fibers in small groups pass into the eyeball, the so-called lamina cribrosa. Nevertheless, though the sclera is not grossly perforated, this spot is the one vulnerable spot in the event of intra-ocular tension, and this lattice work is the first to recede under pressure. The neighboring resistant sclera surrounding this lattice-work area affords a non-yielding ring over which the fibers, in their spray-like arrangement, pass in their distribution to form the retina. These fibers are broken and pinched by pressure until atrophy supervenes, which can be likened to a hernia which is strangulated in its unyielding hernial ring. Over these precipitous edges or eaves the vessels from and to the nerve-trunk are forced to take their course, disappearing over the eaves like drain pipes, and reappearing at the bottom of the cup or excavation. Late in the atrophy, through shrinkage of nerve-fibers, these small fenestrae of the lattice work can be seen, too, at the bottom of excavation. With the atrophy of the optic-nerve fibers which go to make the retina, of course loss of vision comes on; central as well as peripheral vision. The nasal field is first to suffer by reason of the temporal side of the retina being made up of the longest fibers from the nerve, and farthest from their center of nutrition, and consequently the most vulnerable in degeneration.

In order to present a comprehensive picture of glaucoma, it will be best to describe the acute inflammatory type, although not the type indicated by the subject of this paper, nor the type intended to be brought out in this discussion. Yet, as a starting point, all forms can be best visualized by shading up and down; up to the so-called malignant type which can strike suddenly and, unrelieved, can go on to complete and permanent blindness through a short and stormy course; and, shading downward, to the type which is the subject of

this paper—viz., the treacherous, unsuspected, non-inflammatory type—without outward sign to warn the patient or to indicate to friends, associates or even the medical man, the insidious, slow but sure oncoming blindness. For this reason, to repeat, it is seldom recognized until the fading vision from atrophy is upon us and beyond any medical or surgical help.

Promodes: A complaint of smoky vision and dull frontal headaches lasting a few hours, which may recur at intervals of a few days or even weeks or months, and which may be mistaken for presbyopic symptoms if the patient is in the forties, may be accepted as due to strain and symptoms of presbyopia alone. Recession of the accommodation near-point might not even put the oculist on his guard with these patients. An added complaint of halo or rainbows around lights with, ordinarily, a frequent necessity for increasing strength in reading glasses, jolts the eye-man into "attention" but means little or nothing to the optometrist or others untrained in the specialty. Generally these symptoms disappear during sleep and rest, and in the very mild inflammatory type these periodic symptoms may not increase much in severity for years, but all this time the optic nerve-head is leading up to atrophy. As these periodic spells recur, vision slowly recedes, accommodation lags and the victim is given stronger glasses. Usually, however, sooner or later an acute flare-up supervenes, after some gastro-intestinal disturbance, mental emotion, obstinate constipation, et cetera, and is ushered in by violent pain in the ears, the teeth, the head, and the region of the eye. Sleeplessness, anorexia, and maybe nausea and vomiting, are only too often accepted as acute gripe with neuralgia in the head. Then vision in the affected eye begins to fail; mere objects are only discernible; and at last the eye is recognized as the seat of trouble. Edema of the lids, chemotic conjunctiva, steamy cornea insensitive to the touch, with shallow anterior chamber and muddy, green iris, dilated, immobile pupil of peculiar green-gray color, oval or eccentric, and an obscured fundus and stony hard eye, complete the picture to the eye-man.

After a day or two or three, more or less, with treatment and sometimes without, the symptoms abate, tension recedes, the eye returns grossly to its usual appearance, vision seems to be restored, and patient goes on relieved for a time, sometimes for a long interval, sometimes for a short interval, and

the attack is repeated. After repeated attacks, however, return of tension to normal is impossible as a result of pathologic changes, and the eye goes into a chronic hard, painful and blind eye. Even though recovery seems, grossly at least, complete between attacks, close examinations show vision to have suffered, and it declines steadily, and the gray-slate-color-change in iris with exposed pigimentary layer at pupil edge, dilated anterior ciliary veins and porcelain-white sclera with sluggish pupil and optic-nerve cupping, make the classic picture. The degenerative corneal processes, scleral ectasia, calcareous lens and atrophy and shrinkage of the globe, form the picture of terminal, chronic, absolute glaucoma.

The above description is that of the entire course of the average primary inflammatory glaucoma, and though it starts in one eye and may long antedate its advent in the second eye, only too often the same process is repeated in the other, for it is regarded as a bilateral disease of advanced life in people of fifty to seventy years of age, most commonly of all among people of the Jewish race.

Shading down from the above picture, types of all grades are found, where symptoms are regarded as "billiousness," "neuralgia," "rheumatic headaches," et cetera; and we gradually come to the least manifest, but at the same time the most fatal form, the simple non-inflammatory form, "the thief in the night," the type that I heard one of the greatest of teachers of ophthalmology say would be about the only thing that, afflicting him, would make him a suicide.

The chief condition calling for differential diagnosis in the inflammatory type is, of course, iridocyclitis. Here we have generally a contracted pupil, but just there is the necessity for caution because glaucoma frequently complicates a former iridocyclitis with iris contracted down and held by adhesions, or even complicates an existing iridocyclitis; and the uncertainty in which we find ourselves as to the proper medication, atropin or eserin, puts us in the position of a person with a torch in one hand a fire extinguisher in the other, undecided which to use, generally concluding in the better judgment to use neither. In fact, the eye of every patient in middle life, or beyond, must be always approached with care and caution in the use of cycloplegics or even mydriatics. The instillation of even such a short-acting mydriatic as cocain has many times precipitated an attack of tension in eyes

that have previously never been known to have any disposition toward glaucoma. A careful eye-man will constantly guard against such ambush by using pilocarpin after the use of cocain, even for the removal of foreign bodies, in patients of such an age. An iridectomy in one eye has been frequently known to precipitate an attack of glaucoma in the opposite eye, adding to the distress of patient and attending oculist.

In general it should always be borne in mind that hyperopes with small, short eyes are chiefly the subjects of such tendency, while myopes with long eyes are rarely so disposed. In the use of all cycloplegics, patients of all ages should be close enough at hand for observation. Once in the experience of the writer acute inflammatory glaucoma was precipitated in both eyes of a young girl of twenty-two years of age by the use of homatropin. Fortunately she was under control, and within a few hours following the onset, vigorous treatment to combat the condition was instituted and proved effective; but such an experience is enough to last a lifetime. In my experience tension, too, has several times developed in cases of iridocyclitis after the use of atropin, where paracentesis and even iridectomy had to be resorted to to meet the emergency of sudden high tension.

It is an unwise and altogether unsafe practice to have patients living out of town continue to use atropin when they are out of reach and observation, and I know of patients who have suffered total and absolute blindness during the interval between trips to the oculist in the city.

In marked contrast to the inflammatory glaucoma described above, with abundant objective as well as subjective symptoms, is the simple non-inflammatory type, where the subjective symptoms are so slow and insidious as not to arouse even the patient until the effect of atrophy comes on, and where scarcely a single outward objective sign is manifested even to the alert and observing oculist. His contracting field is often not discovered by the patient because his central vision usually remains very good. The distended anterior ciliary veins around the cornea may be enough to arrest his attention, but even this is not prominently present until the condition is of rather long duration. Prior to the invention of the tonometer by Schoitz, of Christiania, glaucoma simplex was not known to be the result of raised intra-ocular tension, for the finger test by palpation could not determine it. In these

cases only repeated tonometer readings, sometimes repeated two or three times a day, are enough to establish the fact.

Just as slight continuous pressure in the dilatation of a uterine cervix by the water-filled placental membranes is more effective for complete dilatation in that structure than forceful instrumental dilatation of short duration, likewise the continuous, constant low-pressure of the slightly raised intra-ocular tension of simple non-inflammatory glaucoma is more fatal and sure of excavation and atrophy in the optic nerve-head than the high-pressure of a violent inflammatory glaucoma attack of short duration. Moreover, an acute attack is so adequately relieved by a properly performed iridectomy that since von Graefe's institution of that procedure the inflammatory type has largely lost its terrors to the ophthalmological world. On the other hand recognition of the simple non-inflammatory type is almost always so long delayed that almost any and all procedures, surgical and medical, are dismally ineffective and of no avail. As a consequence, announcement of the presence of the simple non-inflammatory type in a given case has the effect of a funeral pall upon us all, and utter hopelessness and despair engulf even the most optimistic youngsters as the result of their reading and teaching, and surely stirs no hope in older men of years and experience. Nevertheless I believe, and I am sure that all of us believe, that the pathology of all forms and types of glaucoma is fundamentally the same, and that if the simple non-inflammatory type could only be recognized as early, antedating atrophy, as the inflammatory type, its relief could and would be just as sure and effective as in the latter.

Let us all, then, be alert in the recognition of the pre-atrophy stage, the stage where the recession of the lamina cribrosa is to be made out on careful inspection; where the cupping can be seen to reach from margin to margin, but before the healthy pink color fades and before the atrophy coming on additionally deepens the excavation and exposes the fenestrae in the lamina as a result of the shrinkage of the fiber bundles. If we are alert at this point and proper medical and surgical relief is instituted, there is no doubt that the malady can be arrested as certainly as in the inflammatory form.

Sometimes the simple form flares up into the inflammatory. It would be fortunate if it always did, for then it would be recognized. For, while the

inflammatory form of primary glaucoma is almost always a disease of middle or advanced age, the simple non-inflammatory type only too often claims its victims from among the comparatively young adults, adding to the tragedy.

The inflammatory reactions of iridocyclitis and glaucoma are different in that the former, when severe, is attended with plastic exudate, while that of glaucoma is distinctly the serous or water-logging process of strangulation. In the purely glaucomatous inflammation of the eye hypopyon or pupillary exudate is not found, a very important point of differentiation between the two diseases. The clouding of the cornea, too, is caused by this same water-logging condition and quickly disappears upon relief of the strangulation, which is not the case in corneal inflammation or keratitis.

The essential condition in all types of glaucoma to be borne in mind is the interference or blocking of the exit of intra-ocular fluid from the eye at the angle of the anterior chamber, be it as a result of a swollen or thickened lens, a congested and enlarged ciliary body that presses the root of the iris forward to the cornea, or to a general hyperemia and edema of the whole intra-ocular tissue, or to the presence of exudate or disintegrated blood elements smearing over and clogging the filtering structure of the ligamentum pectinatum and Schlemm's canal. The effect is the same, viz., a disturbance of balance between the incoming and the outgoing fluids of the eye resulting in pressure and strangulation of retinal structures which eventually atrophy and perish.

The only communication from the posterior chamber to the anterior chamber of the eye is through the circumlental space, and in case this space is impinged upon by a disproportionately sized lens as a result of swelling, the lens acts as a valve seated against the ciliary processes and iris base. The increasing pressure thus pushes these structures forward, jamming the angle of the chamber and shutting off the exit of intra-ocular fluid from the eye.

The most favorable factors for this condition are a small eye, shallowness of anterior chamber, a large ciliary body and a disproportionately sized lens. Towards all of these we have a tendency as age advances in the originally hyperopic eye, and in many instances only the added peripheral thickening of the iris when dilated is necessary to pre-

cipitate the blocking of exit for the fluids, and the strangulation sets in.

Iridectomy for relief of glaucoma should always be done as early as possible by making section well into the sclera, rather than in the cornea, and should be as broad as possible and to the very root of the iris. Where regional atrophy exists in the iris, the iridectomy should be done in the least atrophic part, for in this region it will be more effective in opening the angle of the chamber. The various forms of sclerotomy, including trephining, have not proved as dependable as the broad iridectomy, and even in the simple non-inflammatory form the latter would, no doubt, be the most dependable if it could be done in early recognized cases. The action and benefits of myotics in the medical treatment, of course, are to be seen in the drawing away of the peripheral folds of the iris at the angle of the chamber such as takes place in active contraction of the iris. Eserin and pilocarpin can be efficacious only where the iris muscles are capable of contracting, surely not where atrophy of that structure makes such contraction impossible. The action of myotics should be welcomed only as a tide-over and not as a substitute for proper surgical relief, for when their effect wears off the tension is likely to return. The liberal use of myotics before operation is a great help. Tension may be partially relieved, anesthesia may be more effective, and the operation is rendered far easier in performance.

Infantile or juvenile glaucoma, hydrophthalmus, buphthalmus or ox eye, is distinctly a disease of childhood, and like glaucoma in the adult is also caused by intra-ocular pressure, due to an obstruction of the avenue of exit of the intra-ocular fluids; but the pathology primarily is, in all probability, a congenital absence or relative absence of the normal drainage passages known as the canal of Schlemm, or an impervious ligamentum pectinatum, and is not due to obliteration of the angle of the anterior chamber from encroachment of the adjacent iris, as in the ordinary adult type of glaucoma. During the years of early childhood the sclera and cornea are relatively soft and yielding, and as a result give way before the increased intra-ocular tension. The eyeball enlarges to tremendous size; hence the popular name, ox eye. The outer supporting coats, almost alone, take part in the enlargement, and as a result the intra-ocular structures, especially the lens, are proportionately small. The

sclera of characteristic bluish-white, the strikingly large cornea, deep anterior chamber, the shreddy, tremulous iris and the prominence of the globe, make diagnosis easy. Examination of the nerve-head will disclose the glaucomatous cupping. The process can go on to enormous size with ultimate total blindness, or, as is frequently seen, it stops spontaneously with some remaining vision, but the eye remains disproportionately large and disfiguring. It may be unilateral, but usually is bilateral. The lens is often loosely held by its ligament, which is either partially or entirely ruptured, and becomes cataractous, and drops to the bottom of the vitreous chamber.

SAN-I-SAL

Newspaper advertisements have appeared during the past month or two advising the obese public of "A Guaranteed Way to Take Off Two to Five Pounds in One Bath." The product advertised is "San-I-Sal, the Pine Hot Springs Bath." It is sold by the San-I-Sal Laboratories, Washington, D. C. The advertising claims are typical of "patent medicine" obesity cures. According to the specifications of a patent granted by the U. S. Patent Office, the "invention" is said to relate to "a composition of matter for producing a medicated bath of particular value in the treatment of obesity." The "composition" is stated to be: epsom salt 90 per cent, baking soda 2 per cent, table salt 5 per cent, Canada balsam 2 per cent, oil of pine needles 1 per cent. The specifications also declare that the substance used in the bathing water has been found to afford "great relief in cases of inflammatory rheumatism and ailments of a similar character." That a mixture of epsom salt, baking soda and table salt with a small quantity of Canada balsam and oil of pine needles should be granted a patent by the U. S. Patent Office as a new and useful invention, makes one wonder just how much intelligence on medical subjects there is displayed by the Patent Office. —*Jour. A. M. A., May 31, 1924, p. 1800.*

LIPOSAN

According to the advertising, Liposan is "a Vegetable Lipoidal Solution" which has chaulmoogra oil as its "medicinal element." Liposan is claimed to be "indicated" in "Abscesses," "Acne," "Anemia," "Arthritis," "Agitans," "Boils," "Bubo," "Cancer," "Chorea," "Cystitis," "Eczema," "Erysipelas," "Furunculosis," "Herpes," "Hemiplegia," "Ivy Poisoning," "Myalgia," "Neuralgia," "Neuritis," "Peritonitis," "Pylorrhea," "Infantile Paralysis," "Pneumonia," "Rheumatism," "Synovitis," "Syphilis," "Salt Rheum," "Tubercule," "Tonsillitis," "Ulcerations (Indolent)," "Varicositis." The proprietors, Hoffman and Hicks, have not requested an examination of Liposan by the Council on Pharmacy and Chemistry, and so far the A. M. A. Chemical Laboratory has not examined the product. A physician will be justified in his refusal to accept the unproved claims of the manufacturer. He might be justly criticized were he to administer intravenously a product which, so far as he knows, is unstandardized and of wholly questionable value.—*Jour. A. M. A., May 3, 1924, p. 1462.*

MENTAL RE-EDUCATION IN THE SERVICE OF MEDICINE

THEODORA WHEELER, M.D.

Rochester, Minn.

Psychotherapy has always been intrinsic to the art of medicine. In the distant past, healers had their charms and amulets. The medicine man of our own American Indians, as of many other primitive peoples, had a psychotherapy, which was one of fright and fury. The fine type of general practitioner we have heard idealized through the past two centuries was the embodiment of a beneficial mental influence, which comes legitimately to the aid of scientific medicine in its war on both organic and functional disease.

With the different stages of medical progress there has been a corresponding amount of insight into the mental factors of sickness, and varying therapeutic methods for dealing with such manifestations have accompanied medical development. During the last twenty years the knowledge of the nature and causes of "nervous" disturbances has been revolutionized. The war neuroses have recently contributed to a general interest in such conditions. From this, and from many other sources, psychotherapy has gained a more intelligent base of operations. At present, among the most effective measures it employs is that of re-education; this signifying the giving to the patient knowledge regarding his own make-up, his moods and his motives, and likewise training him, as an individual, up to his maximum of what Dr. Adolf Meyer has aptly expressed "constructive composure."

The older order of treatment of the minor functional troubles presented a great range of variation. Sometimes an exhortation, or clapping of the unfortunate "neuropath" on the back, was followed with a tonic or with the assurance that nothing was wrong. On the other hand, there was considerable urging the patient to get well solely by dint of will and conscience, and without any knowledge of himself. Or frequently the physician, in paying careful attention to a rather unimportant physical abnormality, fixed a neurosis on an organ that had hitherto largely escaped the patient's notice. The doctor thus became, professionally, a factor in the production of a more chronic disability. It often happened that the physician himself summarily condemned the patient, ignoring those phases of

the situation which might be subject to improvement. A spirit of denunciation made the patient on the defensive and apologetic from the start. Sometimes this assumed the form of an exaggerated hypochondriasis, or self-depreciation, with real bewilderment. On the other hand, many times it bred an over-compensatory attitude of belligerency and dissatisfaction with the physician, to the detriment of the profession as a whole. It also provided the basis for the development of various present-day cults. These cults flourish on the emotional ills of the people, aided and abetted by the failure of the medical profession to meet psychic as well as physical needs of patients. Fortunately, better methods are gradually superseding these unsatisfactory forms of therapy, which were born largely of ignorance. No adequate teaching of medical psychology had been given in the medical schools. The physician's ignorance of psycho-dynamics, plus the pressure of his work, could not help but breed a most discouraged state of mind medically. Even now, in the gradual development of medicine, one too often finds the physician giving more time to a trivial physical disability than to a complex personality disorder. The patient himself is making strenuous, if unsuccessful, efforts to understand himself and needs the help of one who might be called an intelligent personality interpreter, who can make the patient himself understand the balancing, as well as the conflicting mental factors present in his make-up.

A physician who honestly devotes effort to analysis of personality is able to offer definite practical help to harmonious readjustment for living. With the sincere effort of the physician to face the patient's life situation, a corresponding ability comes to the patient, who previously had feared to meet reality. In fact, the overdeveloped measures of defense, such as hypochondriacal complaining, defiance, and doubt, are born of fear, and when courageously challenged are susceptible of control.

At the basis of any sound psychotherapy there must be specific insight into the condition. The well-known English neurologist, Buzzard, says, regarding this: "Born of the needs of the consultation room, within the past twenty years the science of history-taking for physical and later for mental disorders has been assuming its appropriate importance. On the physical side this has been accepted without demur, but on the mental side it has been met with a volume of resistance which only time

and education are slowly breaking down." As one of our own leaders, Dr. White, has expressed it, "The method of estimating the patient's condition by what he is pleased to volunteer regarding it, has been found increasingly less satisfactory. Conscientious physicians are no longer content to take as final the patient's account of his discontent, his nervousness, sleeplessness, or general indifference, any more than they are willing to let a cough go uninvestigated."

With a proper inquiry into the causes underlying a "nervous" upset, there follows, in the logical treatment of the condition, a systematic enlightening of the patient with regard to his own make-up, and training to efficiency.

The process which marks a therapeutic change is a very dynamic one and alive with the keenest of life's intensities. The term "transference" is serving a useful purpose at the present time in describing that part of the process which deals with the personal relationship of patient and doctor. The physician forms a buffer between the patient and the world, and is the first recipient for new formed attitudes of mind. There are infantile habits to be changed, and poorly conditioned reflexes to be replaced by new ones. The method of attack has to be definite; no generalities or platitudes will be of use. While the physician is oftentimes in a passive rôle, yet ultimately his rôle must be an inquisitorial one. He has to be quietly on his guard, ready to enforce his points at the moment required, remembering, however, that much brilliant conversation is useless with hysterical or neuropathic patients; they are interested in themselves, not in another person. Through "therapeutic tact, rapport, experience," or what you will, the physician is able to give the patient a new moral balance, a broadened sense of obligation, or, in other words, a practical philosophy of life, suited to his abilities.

In this treatment of the individual, rather than the apparent disease, and in this temporary domination of personality over personality, oftentimes really remarkable reorganizations of lives can be effected. Unhappy, maladjusted people learn to drop their frantic, panicky, misdirected struggles, through which they are fleeing from their weaknesses and handicaps. With increasing success they become able to control their emotions and activities, and enter into normal social relations again, gaining the capacity to maintain a healthy, active attitude in the face of difficulties.

From time to time, physicians specializing in this type of work have put forth some constructive idea that they have elaborated in the process of re-education of patients. Recently two physicians, at different ends of the country, whose time has been devoted chiefly to psychotherapy, have each published a book containing suggestions of value regarding the process of personality reorganization. The reference is to Dr. Jackson of Pasadena, California, and Dr. Gehring of Bethel, Maine. The titles of their books are, respectively, "Outwitting Our Nerves" and "The Hope of the Variant." These books have in common the idea that intelligent self-knowledge given to patients is a powerful help in promoting their reinstatement to social efficiency, and that people can, in a large measure, choose the moods, emotions and activities that go for healthy and happy living. Dr. Gehring's work was precluded several years ago by Herrick's "The Master of the Inn," a book written from a patient's experience and point of view.

In Dr. Gehring's present study, the personality of the variant, or potential neuropath, is said to be within the wide range of nature's normal zone. The author shows that the variant can obtain a calm state of mind and cultivate a sturdy, optimistic attitude toward obstacles. Such a one must learn that many of his worries and chronic fears are born of a faulty habit of comparing himself, detrimentally, with others, which can be replaced by the quieting feeling of security that he only has to know and be loyal to the best in himself. One particularly suggestive point Dr. Gehring has studied out is that obsessive concepts come through the channels of feeling, and that they can be modified and often made to disappear by the process of getting them formulated or crystallized into words.

Dr. Jackson's book deals more explicitly with instincts and emotions, which she explains are the well-springs of behavior. These lie deep in each individual's personality and are bound up with much custom, tradition, and a variety of thought processes called rationalizations; the purpose and result of these latter being to justify, on supposedly intelligent grounds, the individual's instinctive course of action. One secret of self-control is in adjusting the receptive portions of the instinct mechanism, so that the threshold is less egotistically sensitive than is that of a neurotic. This process can be made possible through re-educational effort. She speaks of what "vital importance it is to society

that its citizens should be taught to solve their inner conflicts and keep well; at the top notch of vitality with well digested food, well slept sleep, well forgotten fatigue, and well used reserve energy." She speaks reassuringly of the day of the long term sentence to nervousness being past. The book has done, and is still doing, good work in the hands of large numbers of patients.

Throughout present day medical literature there are innumerable short articles on the same general subject. The appended bibliography, used in the preparation of this note, gives an indication of how widespread are the tributaries of this current medical development.

In concluding, the broader implications of the subject may be mentioned. Re-education is, in reality, but one aspect of that larger problem of education which faces each one of us. Progress is accomplished through specialized effort becoming more readily available in the service of different fundamental obligations confronting each member of the "responsible generation." One does not need to find himself a professor of medicine, or such an exalted being as a member of a committee on medical education, or even a representative of a special branch of medicine, to take note of such considerations; for the challenge comes to each physician, parent, teacher and friend, to do what he can to further honest and ungarnished self-knowledge and purposeful social accomplishment.

ZINC-BOROCYL NOT ACCEPTED FOR N. N. R.

The Council on Pharmacy and Chemistry reports that, according to the Al-Sano Chemical Products Co., Zinc-Borocyl is a definite chemical compound. The label of the trade package gives "boridiorthotic oxybenzoic acid zinc" as a synonym for Zinc-Borocyl, but it also declares that the product which is marketed is not the substance to which the name "Boridiorthotic oxybenzoic acid zinc" is applied, but that "the contents of this bottle represent a concentrated solution" of this product. From the information furnished the Council and the statements on the label and in the advertising, it may be concluded that "Zinc-Borocyl" is a solution containing the so-called zinc borosalicylate in undeclared amounts. Its exploitation is essentially an attempt to introduce an old German nostrum—Mucosan—to American physicians under a new name. Zinc-Borocyl is offered as a germicide, antiseptic and astringent, and is recommended for a host of conditions. The Council declared Zinc-Borocyl inadmissible to New and Non-official Remedies because (1) its composition is not correctly declared; (2) it is an unoriginal preparation marketed under a proprietary noninforming name; (3) the recommendations for its use are not upheld by acceptable evidence, and (4) the available information fails to show that the product claimed to be zinc borosalicylate has any advantage over established zinc salts.—*Jour. A. M. A., May 24, 1924, p. 1712.*

FERRASSIN NOT ACCEPTED FOR N. N. R.

The Council on Pharmacy and Chemistry reports that Ferrassin is marketed by Robert Wollheim in the form of tablets and capsules. They are said to be composed of "Vegetable Iron," "Peptonized Iron and Manganese," "Plant Albumin," and Milk Sugar. No information is furnished in regard to the composition of "Vegetable Iron" or of "Peptonized Iron and Manganese." Ferrassin was declared inadmissible to New and Non-official Remedies because its composition is secret and it is marketed with unestablished and unwarranted claims.—*Jour. A. M. A., May 24, 1924, p. 1712.*

THE USE OF CONCENTRATED FOODS IN THE FEEDING OF INFANTS AND CHILDREN*

WOODARD COLBY, M.D.
St. Paul

In the past few years far-reaching investigation has been carried on in the feeding of infants and young children with concentrated food. Such feeding, however, does not constitute a new procedure; for foods of high caloric value which could be given in relatively small amounts have been used for years.

However, it is not until a comparatively recent date that any food other than the most dilute mixtures of milk has been used in feeding premature and new born babies. This has been true because of the established belief that these infants lacked the ferments requisite to the proper function of digestion. But late research shows that protein, carbohydrate and fat ferments are present in the gastro-intestinal tract very early in fetal life, pepsin having been found in the gastric mucosa even as early as the fourth fetal month. During the fifth and sixth months lipase and trypsin appear, while hydrochloric acid, rennin, secretin, erepsin, steapsin, maltase, diastase, ptyalin, invertin and saccharase have all been found at various later months. Lactase is one of the last ferments to occur and is therefore absent in some prematures, but makes its appearance at once when food is given. It can be said that all the necessary ferments are present at birth or as soon thereafter as food is administered, since food acts upon the ferments directly as a stimulant.

Lack of ferments then is not a cause of the difficulties and peculiarities of digestion in new-borns, but rather the cause is physical frailty. Prematures are naturally weaker than full term babies and in their feeding it is of highest importance not to overtax their physical capacity. Therefore it is essential to stress the principle of quality in solving the problems of feeding of prematures and new-borns.

In the solution of feeding problems of weak babies other than new-borns and of young children who are frail, the use of foods rich in nutritive

*From the Miller Hospital Clinic and the Pediatric Department of the University of Minnesota Medical School.

*Read before the Medical Forum, December 6, 1922.

value which could be given in small quantities is not a new thing. Two such foods are Keller's malt soup and thick cereal feeding. The former was valuable not only because of its composition but also because considerable nutrition could be given in small volume. Ingredients: one-third litre of whole milk, 600 grams of water, 100 grams malt extract, and 50 grams flour. The value of thick cereal feeding in pylorospasm and pyloric stenosis has long been firmly established, since in these conditions it is especially important that the retained food be of high caloric value. The many excellent results reported have shown the wisdom of this food even in spite of the fact that starch may cause severe disturbance in infants and young children.

Among the present day preparations receiving most attention are:

1. Thick cereal mixtures with the directions given by Sauer forming a basis for various formulas as used by Graves, Chapin, Mixsell and others. Sauer's directions: To 9 ounces skim milk and 12 ounces water add 6 tablespoons farina and 3 tablespoons Dextri-Maltose. Cook until thick.

2. The Dubo of Schick, whole milk with 17 per cent sugar.

3. The concentrated eiweiss of Finkelstein, prepared as the original eiweiss without the addition of water, plus 10 to 20 per cent carbohydrate.

4. The Czerny—Kleinschmidt butter-flour mixture. Ingredients: 7 grams butter, 5 grams sugar, 7 grams flour, 100 c.c. water. To be mixed with milk as indicated. For ease of preparation three times these amounts can be used. The butter is heated in a pan over a slow flame until bubbles appear and any odor of volatile fatty acid has disappeared. To this the flour is now carefully added and both ingredients again gently cooked with continuous stirring until they become a thin, smooth brown mixture,—to which is added the previously warmed water in which the sugar has been dissolved. The mixture is again brought to a boil, strained and then added to the desired amounts of milk.

5. The butter-flour whole milk and the butter-flour cereal of Moro. The butter-flour whole milk is composed of: 5 grams of butter, 3 grams of flour, 7 grams of sugar, and 100 grams of whole milk. This is prepared much the same as C.-K. butter-flour mixture except that the volatile fatty acids are not driven off by heat.

The butter-flour cereal is made with: 5 grams of butter, 7 grams of flour, 5 grams of sugar, and 100 grams of whole milk. This is boiled to a cereal and fed with a spoon.

In the discussion of the value of the concentrated feedings there is much of interest. That the thick cereal feedings are of decided value in pylorospasm most investigators agree. Since the work of Sauer many results have been published. That it has a quieting effect on a sensitive, irritable pylorus there is no doubt. It also prevents aerophagy, which is an important element in the production of habitual vomiting. Also due to its composition it cannot be vomited as easily as the thin mixtures. Preliminary gruel feedings often stop a mild vomiting in breast fed infants in a day or two. As a complemental feeding to the breast fed infants who do not thrive in the first six months it is excellent because it adds several carbohydrates to the diet in concentrated form without the giving of much fluid. Its use, however, is limited to those infants without a nutritional disturbance. Many pediatricists claim that breast fed infants take the gruel feedings earlier than those artificially fed because the breast milk furthers the digestion of the starches. In exudative diathesis of the edematous form it allows the giving of food without the additional amount of fluid. In constipation it adds bulk and may be very laxative if sufficient carbohydrate is added. In chronic bad feeders good results are published by Chapin, Mixsell and Graves. Chapin reports a series of twenty cases of marasmus treated with whole milk mixtures, with the addition of flour and sugar in various proportions, in which the results were for the most part good and an analysis of the stool showed an assimilation of carbohydrate almost comparable to that of normal children. Graves had good results with thick cereal mixtures made with farina and cream of wheat, which he prefers because of their property of expansion, making a thick mixture with the addition of a minimum amount of starch. He lays emphasis upon the examination of the stools. However, the presence of starch in the stools if symptoms of colic are absent is not of great importance. In normal nursing babies an insufficient supply of breast milk may be supplemented by the cereal feedings, and the infant who receives solid food early in life has a firmness and an excellent muscle tone that is lacking in babies kept too long on a milk diet only. The early feeding is also an

advantage in paving the way to the easy addition of other foods when the time comes.

Results with the Dubo feeding (whole milk and 17 per cent sugar) are published by Schick, Schick & Helmreich, von Groer, Heller, Davidson and Lust. Schick uses this preparation in the new-born ward and gives the infants food on the first day of life. His results are very good. The so-called physiological loss of weight is usually prevented and many gain from the first day. Vomiting is not frequent. The stool changes from a meconium to a food stool on the second day of life. As soon as the mother's milk can be obtained in sufficient amounts the substitute feedings are omitted. Heller, following the teaching of Schick, had good results in prematures; he found the food excellent due to the small amounts necessary to produce growth. Beginning the feedings a few hours after birth, he found that loss of weight could be prevented and that new-borns show the same tendency to rapid growth as the fetus if only enough food is given. However, he agrees with Von Reuss that they must have the ability of water retention. After the new-born period his best results are with Dubo as an additional feeding to human milk. With Dubo given alone his observations show three stages: marked thriving, weight at a standstill, and loss of weight. This was after weeks of continued feeding. Schick emphasizes that the tolerance of the child must be carefully watched if the feedings are to be given over long periods of time, and that as soon as any dyspeptic symptoms appear a lowering of the food to the minimum is necessary and then a gradual return to the optimum. Lust had excellent results with new-borns. He knows no artificial food that gives such excellent gain in weight, and finds it even better than breast milk. But he finds that the percentage of children who go over into dyspeptic conditions after its long continued use is not small. In combination with breast milk his results were good and dyspepsia was seldom seen. Von Groer had excellent results in the acute infectious diseases and dysentery, with Dubo plus the other concentrated foods.

In the Czerny-Kleinschmidt butter-flour mixture the authors attempted to make a food very similar to breast milk in composition. The fat and carbohydrate percentages are kept high and the protein is low. The carbohydrate is partly starch which is dextrinized by heat in the preparation. They lay stress upon its value as a food owing to:

(1) the driving off of the volatile fatty acids; (2) an amount of flour equal to that of the fat; (3) chemical alteration of the flour; (4) the high carbohydrate and fat percentages; (5) the low protein. They advise the food for young and premature infants much below weight who have not been made to thrive on other foods, having a special value alternated with breast milk. They do not recommend it for infants with acute digestive disturbances, with or without fever.

Not all agree that much of its value lies in the fact that the volatile fatty acids are driven off by heat. Moro especially argues against this point, and in his butter-flour whole milk we have a preparation with the same ingredients as the Czerny-Kleinschmidt formula but in the making of which the volatile fatty acids are not driven from the butter. The relation of fat to carbohydrate is as 1:1.7, which is the same as that of human milk. The results reported by Moro and his followers are quite as good as with the C.-K. preparation.

As a standard artificial food for all cases no preparation can be discussed as such. High fat, high sugar, and high protein formulae have their limited uses, but none take the place of human milk in infant feeding. When we consider that many artificially fed infants thrive on very rich mixtures it becomes evident that the powers of assimilation vary within wide limits. This is as a rule for short periods of time only, for sooner or later a high percentage of these children show symptoms of dyspepsia. For good thriving a food must contain at least the minimum requirement of all elements necessary for growth. This was not true of the old third milk mixture and its use has practically been discontinued in all clinics. High fats and high proteins are usually well borne for long periods of time and the onset of dyspeptic symptoms is slow. With the high sugar feedings the onset of any disturbance is usually rapid and a return to the normal is usually accomplished in a few days by a low carbohydrate feeding. The stage of repair after an exceeded tolerance with fat is usually slower. In the using of the concentrated preparations it becomes necessary to raise the percentage of fat and sugar beyond what was formerly regarded as safe for infants and young children. We know now that these high percentages can be given if we maintain a fairly definite relationship of the elements. High fats can be given with perfect safety if we raise the carbohydrate. This

knowledge has been used by Czerny and Kleinschmidt in their butter-flour mixture, and by Moro in his butter-flour whole milk. Following another well founded principle that high carbohydrate can be given with a high protein percentage, Finkelstein made his concentrated eiweiss milk. The reason for the success of the Dubo of Schick is also partly due to the high protein content of cow's milk.

We must also consider growth with the concentrated foods. Until the last few years the amount of fluid required for the thriving new-born was thought to be that quantity taken in breast milk. The work of Schick and Helmreich and that of Heller has shown that growth is in every way normal with the fluid reduced one-half. With a triple concentrated food growth took place equally well. The urine, however, became only a few cubic centimeters in amount, dark in color, and often showed traces of sugar. The temperature at times was elevated. These symptoms disappeared with the giving of more fluid and this fact is often used as an argument against the limited giving of water. For healthy infants with a good appetite who will take large quantities there is no reason for this limitation. It is in the dystrophic cases that the more concentrated preparations have their place. It is the under-nourished, non-thriving infant who needs much food. This has long been recognized, but to administer this amount of food has been the problem because of the dilutions used. These cases often have a bad appetite and are prone to vomit. With an increase in the quantity of food the vomiting increases and the condition becomes worse. With the thick preparations many of these cases show rapid improvement. In a recent paper Finkelstein says that we must free our minds of the traditional view that infants in a state of dystrophy cannot take foods without high dilutions. He also points to the work of Schick with Dubo and says that sugar is not to be feared as a cause of fermentative diarrhea and toxic conditions as was formerly believed. However, the fact remains that these infants do remarkably well on preparations where much nutritional value can be given in small quantities. Extra fluid can be given between feedings if it is the hot time of the year and necessary for the comfort of the patient.

SUMMARY

Food which can be given in small volume is indicated in:

A. The well child:

1. Those who need to be fattened.
2. Those with lack of appetite.
 - (a) New-borns and prematures.
 - (b) Anorexia.
 - (aa) Of nervous origin.
 - (bb) Following an acute illness.
3. In infants with intertrigo and maceration of the skin due to constant wetting of their clothes.
4. In enuresis.

B. The sick child:

1. With anorexia—the influenzas.
2. Those with continued vomiting.
 - (a) Nervous vomiting.
 - (b) Pylorospasm.
 - (c) From severe coughing.
 - (aa) Pertussis.
 - (bb) Pneumonia.
 - (d) In acute infectious diseases.
3. Those with difficulty of taking food.
 - (a) Sore throat.
 - (b) Dyspnea—pneumonia, croup, diphtheria.
 - (c) Disturbances of cerebral function—typhoid and meningitis.
 - (d) Tetanus.
4. In diarrhea.
 - (a) Typhoid.
 - (b) Dysentery.

As contra-indications:

1. The healthy child who needs volume to satisfy the pangs of hunger.
2. Cases of acute vomiting and diarrhea of alimentary origin.
3. When children cannot be under absolute control.
4. Not to be used over long periods of time but as a therapeutic measure only.

PREGNANCY WITH COMPLICATIONS:
FIBROIDS; ECLAMPSIA; CESAREAN SEC-
TION; ACUTE GASTRECTASIA; THROM-
BOPHLEBITIS: CASE REPORT

DANIEL H. BESSESEN, M.D.

Minneapolis

The patient, aged 32, presented herself at the end of the first trimester. Aside from the present illness, the history is without interest. She believed herself to be pregnant, having menstruated for the last time on October 18, 1921. Previous to that she had had menstrual flow of moderate amount occurring regularly every twenty-eight days, lasting for three days without pain. At the first examination she complained of slight frequency of urination, poor appetite, occasional nausea and headache. The physical examination disclosed a nodular mass in the pelvis interpreted as an enlarged uterus probably of pregnancy with hard fibroid tumors through its body. The patient was carefully observed each month and the diagnosis corroborated. The blood pressure, urine and general condition remained entirely normal throughout the first eight months. At this time she suffered from false labor pains and was sent to the hospital on the suspicion that delivery might take place. The family was instructed that abdominal cesarean section might be necessary because of the fibroid condition of the uterus. As the pains stopped, however, the patient returned home. When seen ten days later, the urine and blood pressure were normal.

On July 21, 1922, three weeks after the false labor, the patient noticed spots in front of the eyes and a short while later had a convulsion. The blood pressure at this time was 160/120. Abdominal cesarean section was performed and a living baby delivered. Following the operation, the blood pressure was 140/100. She was placed on morphin and chloral hydrate, and after a small temporary rise in blood pressure, the tension fell on the following morning to 136/88 and remained in that neighborhood. On the second postoperative day, she complained of great distress and 32 ounces of a dark brown fluid containing flocculent material was removed from the stomach. An attempt was made to insert a Rehfuß tube, but the patient could not swallow it; so the stomach was washed out through a stomach tube with water containing 2 grams of tannic acid. Five minims of pituitrin

were given hypodermically every six hours. This resulted in a slight rise in blood pressure, but gave the patient much relief. At the same time enterocolysis was started. On the tenth postoperative day, the temperature was elevated and the cervix was dilated. The fever dropped in three days, but on the fourteenth postoperative day, the patient complained of pain in the left calf. Several small masses were distinctly felt near the surface, and the limb was raised and surrounded with ice caps. The thrombophlebitis was completely relieved by the sixteenth postoperative day and the patient left the hospital on the twenty-second day. Unfortunately, in spite of the care of capable pediatricists, the baby died on the fourteenth day.

The presence of fibroids in the uterus is a subject which requires careful consideration as to prenatal care and management of the delivery. The uterus on exposure in this case showed such a multiplicity of nodular growths that for this condition alone, cesarean section would likely have been necessary. In addition to the larger growths which could be palpated through the abdominal wall there were many (perhaps 200) smaller masses scattered over the entire surface and planted in the various muscular layers of the uterus which had not been palpated previous to operation.

Among other things, eclampsia has been attributed to infarct formation in the placenta with absorption of the autolyzed tissue. In this case, there was present on the surface of the placenta an area approximately three-fourths of an inch in diameter which showed degeneration, and might probably have been loosened at the time of the false labor pains, since previous to the actual appearance of the convulsions there was little indication of eclampsia. There is a difference of opinion as to the treatment of choice in eclampsia, though it may be said that operative treatment certainly offers a lower mortality to the infant and perhaps also to the mother over the expectant treatment. If operation is to be performed, it should be done not later than six hours after the first convulsion.

Acute gastrectasia is a not uncommon condition, though its presence is usually an indication of a weakened patient, since it most frequently occurs in patients in poor condition. Its mortality is variously estimated at from 50 to 75 per cent. The seriousness of this condition is easily offset by early recognition and prompt treatment. The stomach tube has long been recommended as the most effi-

cient remedy for gastrectasia. The action of the tannic acid which was utilized in this case serves to coagulate the blood and stop bleeding points in the gastric mucosa, in addition to acting as an astringent. Pituitrin acts as a stimulant to smooth muscle, thus serving to bring the stomach to its normal size and function. Repeated small doses extend this effect over a longer period of time.

The slight retention of lochia on the tenth day resulted from the insufficient dilatation of the cervix and secondary to this was the thrombophlebitis which occurred in the left leg. It is well to watch for retention in cases which have been delivered via cesarean section, since seldom has the cervix been dilated and the lochial flow may be slightly checked. The severity of the thrombophlebitis may be aggravated by failure to recognize the source and promptly eliminate it.

There were two indications for cesarean section in this case: first, the fibroids in the uterus, and, second, the eclampsia. Conditions tending to infection contraindicate this proceeding. Vaginal examination had been done early in the onset of gestation and strict hygiene had been observed, so that the possibility of infection was so slight as to justify immediate operation. It might be questioned why the Porro cesarean section was not done, but the patient's condition would not warrant it.

TERSUL-HILLER NOT ACCEPTED FOR N. N. R.

The Council on Pharmacy and Chemistry reports that Tersul-Hiller (Robert Wollheim, distributor) is a German preparation of silicon and calcium proposed as "An Adjuvant to the Treatment of Tuberculosis, Rachitis, etc." Physicians are told that Tersul-Hiller is "composed essentially of coincidentally water-soluble silica and water-soluble calcium salts as shown by the following approximate percentage formula: Silica (new process) $4\frac{1}{2}$ gr., calcium lactate $7\frac{1}{2}$ gr., calcium hypophosphate $\frac{3}{4}$ gr., calcium phosphate $7\frac{1}{2}$ gr., calcium fluorid $1\frac{1}{2}$ gr., calcium carbonate 60 gr., magnesium phosphate 3 gr., milk sugar 15 gr." From this formula it would appear that Tersul-Hiller is a mixture containing a silica compound of undeclared composition and a mixture of soluble and insoluble calcium compounds—chiefly calcium carbonate. The Council found Tersul-Hiller inadmissible to New and New-official Remedies because (1) there is no acceptable evidence for the therapeutic use of silica preparations; (2) the identity of the silica compound is not declared; (3) the use of the mixture is irrational, and (4) the claims for its therapeutic effects are unwarranted.—*Jour. A. M. A., May 24, 1924, p. 1712.*

A CONSIDERATION OF POSTOPERATIVE COMPLICATIONS FOLLOWING THYROIDECTOMY

THOMAS O. YOUNG, M.D.

Fellow in Surgery,
The Mayo Foundation
Rochester, Minnesota

A review of the literature on surgery of the thyroid gland disclosed very little data on operative complications and treatment following thyroidectomy, practically all articles dealing with surgery of the thyroid being on preoperative treatment, actual technic, or end-results. In view of the fact that the recognition of such complications and treatment have such a definite bearing not only on the immediate, but on the ultimate results, I reviewed the case histories in the Mayo Clinic with regard to the postoperative complications of about two thousand patients on whom thyroidectomy had been performed for exophthalmic goiter and adenomatous goiter, and personally observed approximately two thousand more.

The purely surgical complications following thyroidectomy fall naturally into two definite groups: (1) those due to a pathologic condition present at the time of the operation, or to a coincident surgical complication developing after operation, and considered unavoidable; and (2) those that are accidental and dependent on the technic of the operation and the personal skill of the operator; these may be considered avoidable in the majority of instances.

Group 1.—Among the unavoidable complications, "collapsed trachea" has been held responsible in many cases in the past. This condition is a definite clinical entity usually occurring in cases of large or hard, nodular goiters. It⁴ is caused by softening of the tracheal rings, the result of pressure. The trachea is held patent by the fascial attachments to the enlarged gland. Thyroidectomy removes the supporting structure, and if there is severe erosion of the tracheal rings, collapse may follow. The inciting cause of the collapse may be rotation of the trachea during operation, pressure from edema, or hemorrhage in the surrounding tissues, or the inspiratory effort, causing the walls to fall together, and act as an obstructive valve. These complications may occur during operation or within a few hours after. Some years ago, difficulty in breathing following such operations was

ascribed to collapse of the trachea, the responsibility of which was not assumed by the operator. In recent years, however, it has been learned that such dyspnea rarely is due to collapse of the trachea, but usually to some other condition. In none of the cases in this series which came to necropsy, could the cause of death be ascribed to collapse of the trachea. When it does occur, immediate tracheotomy, to avoid death by asphyxiation, is necessary. The trachea must be supported either by a tracheotomy tube, sutures, or packing, until sufficient adhesions have formed to hold it patent.

Tracheitis and laryngitis, with the edema of the trachea and larynx, are present to a certain degree in a large percentage of cases following thyroidectomy. This is the result of manipulation, of mechanical injury to the trachea because of its immediate proximity to the field of operation, and of alteration of the blood supply in this area. The closer and more extensive the association between the thyroid and the trachea, the greater will be the reaction. In most instances, the reaction will be mild and transient, manifesting itself by an increased amount of viscid mucous sputum, and a thick, hoarse voice; it may, however, be much more serious. The onset of the edema in this type of case is usually within two to four hours after operation. The patient gradually becomes hoarse, and breathes with increasing difficulty. Injury to the recurrent laryngeal nerve may or may not accompany this condition. Laryngoscopic examination will reveal edema of the larynx and the trachea and vocal cords; in some cases the air passage will be narrowed markedly. This condition rarely, if ever, progresses to the point of operative interference unless accompanied by injury to the recurrent laryngeal nerve. The constant inhalation of steam with compound tincture of benzoin affords the greatest relief to these patients. The patient should be entirely inclosed in a tent, so that he will constantly breathe an atmosphere saturated with steam. In twenty-four hours the patient will usually be markedly improved.

Occasionally coincident surgical conditions may be included under the heading of unavoidable complications, although they are naturally rare. Two cases were noted in which acute appendicitis developed within forty-eight hours after a thyroidectomy. The patients were operated on and convalesced uneventfully, although there must have been a very definite increase in the operative risk.

In a case of acute cholecystitis with stones following thyroidectomy for exophthalmic goiter, the patient was treated medically and carried through the postoperative stage. Another patient developed definite signs of intestinal obstruction a few days after the original operation, but symptoms subsided before operative interference was necessary. Menstrual complications are sometimes distressing, and, though not dangerous, may definitely prolong convalescence. One patient had a flare-up of an old salpingitis several days after operation. The condition was treated for about three weeks, when operation was performed.

Group 2.—Among the accidental complications that are dependent on the technic and skill of the operator, paralysis of the vocal cords, due to injury of the recurrent laryngeal nerve, is by far the most serious. From the standpoint of complications and the relation to operative risk, such injuries are of two types: transient paralysis,¹¹ the result of pressure or manipulation of the recurrent laryngeal nerve, and permanent paralysis,³ the result of clamping, cutting, or ligating the recurrent laryngeal nerve. The first type, which has little effect on the convalescence, may be manifested by partial or complete abductor paralysis of the vocal cord. It is sometimes difficult to determine whether this is due to local edema, or to partial or temporary nerve injury. The paralysis usually clears up in from one to three weeks. If the recurrent laryngeal nerve is cut, clamped, or ligated, there is complete paralysis of the corresponding vocal cord, which is usually permanent. In a few cases in which the nerve is only torn or crushed, regeneration may occur, and the vocal cord return to normal after several months. The paralysis may be either unilateral or bilateral; it has a definite bearing on the immediate convalescence, and on the future well-being and happiness of the patient.

Injury to one nerve may result in definite hoarseness, or there may be no perceptible change in the voice. There may or may not be signs of obstruction to breathing. If dyspnea is present, it is usually complicated by local edema. Regardless of whether or not this is the case, the convalescence of the patient is usually definitely protracted. Examination of the vocal cords may reveal the cord on the side of the injured nerve fixed in the abductor or in the cadaveric position, and without movement on attempted phonation. However, with one normal cord there is not sufficient obstruction to

affect materially the every-day life of the patient after recovering from the operation. The voice usually approaches the normal as the other vocal cord hypertrophies in accommodation. There is little doubt, however, that in the presence of unilateral vocal cord paralysis,⁸ there is a definite increase in the mortality in event of complications such as a crisis, pneumonia, or acute infectious disease.

Bilateral vocal cord paralysis⁵ due to injury to both recurrent laryngeal nerves is a serious complication. The immediate effect on the voice is not always the same. The patient may still be able to talk, but with a peculiar, characteristic, brassy type of voice. When once heard, this type of voice will always associate itself with paralysis of the vocal cords. The patients may or may not have immediate partial obstruction to breathing. If it does not occur at once, it usually develops to some degree within twenty-four hours. Frequently dyspnea, and at times stridor, are the only symptoms. Laryngoscopic⁷ examination of the vocal cords of this type shows both cords fixed in the abductor or median line position with a very narrow slit between them for the passage of air. Patients must be watched carefully, by an experienced nurse, as their surgical risk is greatly increased. Any transient, acute infection might be sufficient to cause death. A tracheotomy tray should be kept in the room, and all in readiness for tracheotomy at a moment's notice. Steam with compound tincture of benzoin should be in constant use with the patient in a tent.

Another type of bilateral cord paralysis is not as distressing, or as serious from an immediate standpoint. The patient has complete loss of voice and talks in a loud falsetto whisper. There is no obstruction to breathing. Drinking water causes a very distressing choking. This is followed usually by coughing and straining. Laryngoscopic examination reveals fixation of the vocal cords in the intermediate or cadaveric position. There is no motion of the cords when talking is attempted. Although there is no obstruction to breathing, the possibility always exists that it may develop suddenly. Here also it is wise to have a tracheotomy tray in the room in preparation for emergency. After a prolonged convalescence the patient usually goes home feeling fairly well except for loss of voice and a tendency to dyspnea on slight exertion. Examination of the vocal cords after a few months

will show them to be contracted to the abductor position. Patients gradually learn to talk in a weak, cracked voice, but are unable to lead a normal existence because of the ever-present dyspnea caused by slight exertion. They may be semi-invalids for years, always living in fear of exerting themselves and of the possibility of a complete obstruction to breathing. Sooner or later attempts must be made to alleviate this condition.

In connection with injuries to the recurrent laryngeal nerve it may be well to mention hysterical aphonia, which should be distinguished from injury to the nerve. The onset may follow operation directly, or it may not arise for several days. In most instances, the voice returns spontaneously. Laryngoscopic examination will at once differentiate this from true vocal cord paralysis.

Hemorrhage following thyroidectomy is another very important accidental complication. There are two distinct types: one occurring within the first forty-eight hours; the other delayed, manifesting itself from ten to twenty days after operation. The first is by far the most serious. It has a very definite effect on the convalescence of the patient, and unless apprehended and arrested early, may be the direct cause of death. If there is an unusual quantity of blood in the dressings, requiring changing more than once or twice in twenty-four hours, the patient should be watched closely for hemorrhage. Seeing the wound with the dressing off will usually determine whether or not the drainage is excessive. If the flow of blood becomes a steady dropping or a small stream, the wound should be opened and the hemorrhage stopped. The bleeding usually comes from a branch of the inferior thyroid artery, from one of the lateral veins, or from a general oozing of the tissues. Undoubtedly the slipping of a ligature during a coughing or vomiting spell is directly responsible for it in many cases.

Hemorrhage⁹ occurring early following thyroidectomy may be accompanied by clot formation. It is much more common and dangerous than the former type. It is caused by slipping ligatures, small vessels overlooked at operation, vessels crushed and starting to bleed during a coughing or vomiting spell, or a general capillary oozing. There are several characteristic symptoms which should be recognized early. The first is practically always mentioned by the patient himself. If he complains that the dressing is getting tight, the wound should be examined. If the bleeding is not apprehended

at this stage, it is usually progressive. The symptoms, as the clot grows larger, occur in the following order: difficulty in swallowing, feeling of a lump in the throat, difficulty in breathing due to pressure on the trachea, and finally complete loss of voice. These symptoms are undoubtedly due to a combination of pressure on the recurrent laryngeal nerve, pressure on the trachea, and the resultant traumatic edema of the surrounding structures. If the symptoms are progressive and the condition not recognized and relieved, the patient will go on to asphyxiation and death. Prompt opening of the wound, evacuation of the clot, and ligating of any bleeding points, or, if none can be found, packing of the wound, will relieve all symptoms with very little increase in the mortality rate.

Late postoperative hemorrhages occur but rarely, and then only in the presence of a particularly virulent type of wound infection. One case was noted in which the hemorrhage occurred on the fourteenth day. The patient had an infected wound and had been having hot dressings. The character of the drainage had become serous, and the patient was dismissed from the hospital. He was brought back on the fourteenth day, bleeding profusely from the wound. Operation disclosed the offending vessel to be a large branch of the inferior thyroid artery which had been eroded by the infection. The vessel was ligated, and the patient recovered uneventfully.

Edema⁶ and ecchymosis of the skin flap do not form a dangerous complication, but may definitely prolong convalescence. The edema itself rarely affects more than the flap. The ecchymosis, however, may be widespread, and involve all the wound area and a greater portion of the chest wall: thus the wound drains longer, and in case of contamination a fertile field for infection is afforded. Sterile hot dressings should be applied every two to three hours for several days.

Infection of the wound is not common, but when it does occur, it assumes a variety of forms and may result in protracted and long drawn out convalescence. Practically all wounds following thyroidectomy were drained. In a few cases, gauze packs were used, and in a few others, wounds were packed with gauze and left open. Following the sero-sanguineous drainage of the first few days, the character of the drainage changes to serous. Cultures of the wounds in this type, taken from the tenth to the fifteenth day, showed either streptococ-

cus or staphylococcus in large numbers. In most instances patients recovered uneventfully without general symptoms of infection. From the standpoint of effect on the convalescence, such wounds cannot truly be considered infected. In a second type there was a sero-purulent drainage. In these, also, cultures were positive, but they usually cleared up after a moderately extended period of drainage. In a third type the infection was more severe, with a frankly purulent drainage. Cultures in most of these cases showed *streptococcus hemolyticus*. Such wounds require sterile hot dressings applied every two to three hours for a considerable period. In the fourth type the wounds drained very little or none, at first. The temperature varied from 100° to 103°, and there was a general feeling of intoxication. The wound was indurated, and somewhat swollen, and the flap reddened. Hot dressings usually produced a purulent drainage within a few days. *Streptococcus hemolyticus* was present. The fifth type is very rare and apparently is caused by an extremely virulent type of organism. The drainage is purulent and profuse with marked sloughing of the flap, causing an ugly scar when the wound heals. Because of the preponderance of operations for goiter in women, the appearance of the scar becomes important. A good scar, in the opinion of the patient, may mean the difference between a very successful operation and a mediocre job. Ugly scars are practically always the result of extensive infection. It¹ is a simple matter, after the wound has healed, to excise this scar tissue and approximate the skin and muscles. Keloid formation is not common, but when present it can usually be controlled by mild doses of x-ray. The skin may sometimes be attached to the trachea at the point of drainage; swallowing causes an elevation of the skin at this point. If this still persists two or three months after operation, daily massage of the neck with cocoa butter will often cause stretching of the scar tissue so that it will not be noticeable. If this does not improve the condition, excision of the scar and approximation of the skin and muscles will remove the deformity.

Air embolism occurs infrequently, and is an operative, rather than a post-operative complication, the result of tearing a large vein, or failure to ligate properly the lateral veins. Three cases occurring on the operating table have been noted. If a large vein is open, air may be sucked in during inspiration. The symptoms are those of cerebral

anemia accompanied by a cessation of respirations, and if correctly interpreted early, prompt lowering of the head of the table and ligating the vein will always bring these patients through. The complications occurred in cases of large adenomatous goiter with enormously distended and tortuous lateral veins. All the patients recovered.

Tetany² as a postoperative complication is now far less common than in the past. It is the result of removal of part or all of the parathyroid bodies, or of interference with their blood and nerve supply. Since the days of complete lobectomy, it is very unusual to remove the parathyroid glands during a thyroidectomy. However, since the adoption of resection rather than complete removal of the thyroid gland, most of the cases are due to interference with the blood or nerve supply. There are two very definite types of postoperative parathyroid tetany, transient and permanent. In the transient type, which is undoubtedly due to interference in the blood or nerve supply to the gland, a heavy milk diet, and calcium lactate by mouth, will usually cure the condition in a few days. For the attack itself, 5 c.c. of a 10 per cent solution of calcium chlorid intravenously will produce immediate relief. In the permanent type treatment with calcium chlorid and parathyroid extract will hold off attacks, but cessation of the treatment is soon followed by their recurrence. In this type there is definite and permanent injury to the parathyroid glands, or to their blood supply. There were no cases of permanent tetany in this series.

Myxedema is an unusual sequela of thyroidectomy. It is caused by the removal of too much gland tissue, infection of the wound with resultant sloughing and destruction of gland tissue, or by the presence of a thyroiditis at the time of operation. The medical treatment of this condition with thyroid extract and thyroxin will re-establish a normal rate.

The incidence of purely medical complications is mentioned chiefly to emphasize the additional complications which must be dealt with. The accompanying symptoms and their treatment will not be discussed in detail.

The crisis of exophthalmic goiter, or the onset of acute hyperthyroidism following operation, is not nearly so common as formerly. When it does occur, the usual treatment of heavy doses of Lugol's solution,¹⁰ digitalis, icebags, forcing fluids by rectum and subcutaneously, with nothing by mouth,

and the liberal use of morphin to combat the restlessness, are the chief forms of treatment.

Acute dilatation of the heart is rarely found except in crisis. Digifolin hypodermically or intravenously seems to be the most desirable form of digitalis. Auricular fibrillation is the usual rather than the unusual condition in the severely toxic cases. Auricular flutter is much more infrequent. The usual treatment by morphin, ice cap to precordium, and digitalis is used.

Pneumonia as a complication is rare, since the use of local and combined anesthesia. It is practically always of the bronchial type and rarely fatal. Alone it does not constitute a very markedly increased risk. In the presence of injuries to the recurrent laryngeal nerve and subsequent vocal cord paralysis, however, the risk immediately goes much higher. The complications of pneumonia, such as dry pleurisy, pleural effusion, or empyema, must be dealt with as such. There is a definite increase in the mortality if these occur early.

Acute follicular tonsillitis sometimes occurs. One case in particular is mentioned because of the fact that the patient, on being questioned, insisted that his throat was not sore. His throat therefore was not examined in the search for the cause of his toxic condition, and the condition was overlooked for twenty-four hours. On examination, the throat was found to be acutely inflamed. The usual hot saline irrigations and steam inhalations suffice to take care of this type of complication.

Most types of acute infectious diseases have been seen at one time or another. Nothing more can be said than that isolation of the case and treatment of the condition must be instituted. The risk is, of course, definitely increased.

Phlebitis following thyroidectomy is rare, and with it there are usually coexistent varicosities. One case was noted. Treatment consisted in rest, elevation, and heat to the limb. Recovery was uneventful.

SUMMARY

The present day interpretation of surgical complications is radically different from that of ten to fifteen years ago, especially with regard to complications causing interference with respiration. We know that practically all of these are due to injury to the recurrent laryngeal nerve, or to pressure on the trachea from clot formation in hemorrhage. Many surgical complications do not markedly

affect the mortality rate, since they are promptly recognized and treated. The most serious of the complications from the standpoint of mortality and the future welfare of the patient is injury to the recurrent laryngeal nerve. The accurate checking by laryngoscopic examination is the only method of determining the degree and type of involvement of the vocal cord; on this, the prognosis depends.

A little more than fifteen years ago, on Memorial Day, a wreck on a trolley line at Elyria, Ohio, caused the death of sixteen passengers and sent half a hundred others to a small local hospital in an old residence. The lack of adequate facilities caused the death of a number, among them Homer Allen, a high school boy, son of Edgar F. Allen, a business man of Cleveland, but a resident of Elyria. The utter inadequacy of the hospital to meet any emergency, its incompleteness even for ordinary conditions, greatly impressed Mr. Allen. It did more; it caused him to resolve to give up his million-dollar business and devote his energies, time and money to ameliorating suffering. He headed an organization to provide Elyria with a hospital that would meet all present and future needs. Large, fine grounds were purchased, and a modern hospital, costing \$100,000, was built. He gave liberally himself, besides proving himself a splendid solicitor. The town was rapidly growing from a beautiful village to a manufacturing city, and five additional units to the hospital have been built. Today the outlay represents \$1,000,000. Mr. Allen assumed the general management without salary, and when the monthly balance showed a deficit he made it up from his own pocket.

About ten years ago a local physician remarked casually that something ought to be done for the crippled children of the city. Mr. Allen thereupon investigated and found that the United States possessed only three crippled children's hospitals, one at Canton, Mass.; one at Haverstown, N. Y., and a third at St. Paul, Minn. He learned all he could of the work being done, but he doubted whether there were enough cripples in Elyria or in the county to justify the erection of a hospital exclusively for them. Investigation, however, soon brought to light twenty young cripples in the city and more than 200 in the county. Mr. Allen's interest grew, and he employed at his own expense a capable woman to survey several nearby cities. He found there was one cripple to every 500 of the population. He

has since found through surveys in many large cities that there is a crippled child for every 400 of the population. This would indicate no less than 325,000 in the whole country. Soon after the county survey was made Mr. Allen presented his findings to the Hospital Board of Elyria and urged the building of a crippled children's hospital, to be placed upon the ample grounds of Memorial Hospital. The request was a distinct surprise and it was doubted if the community could at that time add this unit, but so great was the confidence in Mr. Allen that he was told to proceed with the scheme, if he could raise the money. A single donor gave \$25,000 as a memorial to her husband, W. N. Gates. In this way the Gates Children's Hospital was founded.

The Edgar Allen idea of local rather than large State or regional hospitals is based upon the economy of the small hospital or ward. They should be in connection with large hospitals to secure the advantage of trained nurses, good medical attendance, nearness to the children's homes and the avoidance of red tape. The academic and industrial education with a vocational turn adapted to the child's possibilities after leaving the hospital has developed wonderfully in some of the cities. It is found advisable to establish day schools for their special benefit in the larger cities. Cleveland has 138 such children in day schools and is preparing for 250 more now on the waiting list. Cincinnati has 120, Toledo 125, Akron 37, with 90 on the waiting list, and so on through a long list of smaller cities. What a contrast this picture presents to that of European cities, where begging cripples line the streets! Not all children can be discharged from the hospitals fully cured or normal, but none is accepted unless he can be benefited. To make the work more effective Mr. Allen is now stressing the need of convalescent homes to relieve the hospitals after operations and to provide better educational facilities and more homelike surroundings.—*Current History*, April, 1924.

Homeopathy

Chapters in history come and go and often the close of the chapter is only realized in retrospect. The chapter in medicine which deals with homeopathy is from all appearances rapidly drawing to a close.

Ask the recent medical graduate what he knows about homeopathy and in all probability all he can tell you is that one of the former schools of medicine prescribed on the theory that like cures like and that drug potency increases with dilution; that neither of these theories work out in practice and that's that. He never heard of Hahnemann's third theory of the "psora" or miasm, which was supposed to manifest itself in some form of skin disturbance. As a matter of fact this third theory never attained much credence among his most ardent followers.

The German physician, Hahnemann, first propounded his theories at the close of the eighteenth century. It was then known that quinine was a specific for malaria and the thought occurred to Hahnemann that quinine administered to the normal human being might produce a reaction similar

to malaria. He tried it on himself. It did. Ergo—*similia similibus curantur*.

Hahnemann's theories gradually spread all over Europe in spite of temporary adverse legislation in Austria and later in England. In no country did these novel ideas find such fertile soil as in our own. Towards the end of the last century homeopathy was flourishing and at its close there were twenty-one homeopathic medical schools in operation in America. Few of the present generation can realize the foothold homeopathy gained among the profession in this country nor the heated debates it caused in our ranks.

Today, just two homeopathic medical schools exist in this country and last year just forty-nine physicians of the school were graduated. Homeopathic physicians who wish to be known as such are comparatively few in number. Homeopathy has come but is now obsolete.*

What is the explanation of the fall of homeopathy? The main reason lies in the fact that in the light of modern scientific medical progress the theories of homeopathy do not hold water. Quinine destroys the *plasmodium malariae* in the blood and is not an instance of like curing like.

The power of publicity in remedying conditions is nowhere better illustrated than in its effect on homeopathic medical schools. In 1901 the American Medical Association began publishing a yearly list of medical schools in the country and their ratings. Since then the number of homeopathic medical schools has rapidly decreased from twenty-one to two. So many of the homeopathic schools had low ratings that together with the falling off in patronage they became discouraged and quit. Many a homeopathic physician realizing the true state of affairs sent his son to a regular school.

Homeopathy has made its contribution to medical progress. If it accomplished nothing else, it counteracted the practice formerly in vogue of administering large doses of drugs. Patients in many instances did as well or better on the almost negligible medication of this school. The present day tendency away from useless medication is doubtless the result of the influence exerted by the school of homeopathy.

*In the June issue of The American Mercury, Morris Fishbein presents the subject of "The Rise and Fall of Homeopathy" in an unbiased and very illuminating manner.

"Dr." Henry Ford

The feeling of criticism of the methods pursued by the management of the Ford Hospital on the part of the medical profession of Detroit attained some publicity when the Detroit Academy of Surgery declined the invitation recently to hold a meeting at the hospital.

As explained in the local medical society bulletin, "The medical profession objects to having Henry Ford, a man of unlimited wealth and power, a man who controls a publication, a man of strong prejudices, practice medicine by proxy."

The story goes that some years back Mr. Ford received what he considered an exorbitant bill for medical services rendered a member of his family. This experience is supposed to have been the inspiration for the establishment of his hospital on a one-price basis. The established rates are based on cost of hospital operation and cover professional services. Millionaire and day laborer presumably pay the same rate.

Report has it that under the direction of its first superintendent, who was well trained along the old lines of hospital management, the institution did not make expenses. The superintendent was dismissed and under the personal inspiration of Mr. Ford's private secretary, modern commercial methods were adopted. Publicity was given to the hospital's possession of a stethoscope, microtome, etc., and the staff of Johns Hopkins graduates only was advertised. Result—the hospital grew by leaps and bounds.

The reply of the surgeon-in-chief, Dr. Roy D. McClure, in a dignified way called attention to the phenomenal growth of the institution which, in his opinion, disproves the accusation of factory methods, and claimed the right to existence of a uniform fee scale.

The gist of the controversy is contained in two questions: first, the propriety of a hospital so closely connected with the professional staff, advertising to the public; second, shall there be a uniform or flexible fee scale?

Most hospitals advertise directly or indirectly and many a physician benefits thereby. It were better if all hospitals adhered to the same policies. When, however, as in the Ford hospital, the physician is paid by the hospital, advertising on the part of the hospital amounts to the same as professional advertising.

Mr. Ford's quixotic attack on the flexible fee

scale generally practiced by the profession is interesting. Only a man of wealth and strong conviction could so disturb the profession. Most hospitals have endowments and at that have difficulty in making expenses. It is not likely that any one hospital in a locality could adopt the Ford hospital system and survive. It would be a question of all or none. Such a system would doubtless be satisfactory to the profession from a financial standpoint, but would throw a greater patronage on free municipal institutions.

It is not generally realized how much medical attention is given voluntarily for little or no remuneration by hospitals and the medical profession. The relatively few large fees attract attention, only serve to commercialize medicine and often are unjustifiable. Sometimes they may act as a boomerang as in the case of Mr. Ford.

Fancy fees only serve to detract from the idea of service which we as a profession must firmly adhere to. The physician who renders service, as a rule, has no great difficulty in the way of financial compensation.

COMMUNICATIONS

435 Hamm Building
St. Paul, Minnesota
May 28, 1924

TO THE EDITOR:

I have just received a letter from Paris from my neurological confrère, Dr. Walton M. Kraus, of New York, but at present in France, calling my attention to Netter's and Urbain's recent work on the "Further Investigations of the Deviation of the Complement in Herpes Zoster."** These investigations indicate the identity of the causative agents of herpes zoster and chicken pox. Dr. Kraus states that from the clinical viewpoint it has been reviewed in America by McEwen (*Arch. Derm. & Syph.*, 1920); Kraus (*New York Medical Journal*, 1921); Riggs (*Minnesota Medicine*, 1922), and that these authors believe that these two diseases are due to the same or very closely related causes.

Netter and Urbain have demonstrated (*Comptes Rendus*, Jan. 26) an antigen obtainable from the sera and crusts of cases of herpes zoster (not labialis, which shows none of the reactions to be described), which fixes antibody of cases of herpes zoster. Further they demonstrated that this antigen has the same action upon blood serum from cases of chicken pox and that antigen obtained from chicken pox crusts also fixed both chicken pox and herpes zoster antibody. They confirmed this on thirteen additional cases of zoster. They conclude from this that the crusts or scabs

**Nouvelles Recherches sur la Deviation du Complement dans le Zona. Arnold Netter and Achille Urbain (*Comptes Rendus. Soc. de Biol.*, Vol. 90, No. 7, p. 461 (1924)).

of zoster contain an antigen capable of deviating the complement of the blood serum of both chicken pox and herpes zoster and that the converse obtains as well. Dr. Kraus believes that this bacteriological evidence added to the clinical evidence already accumulated emphasizes the probable identity of the causes of chicken pox and herpes zoster.

Very sincerely yours,

C. EUGENE RIGGS.

OBITUARY

DR. HALDOR SNEVE

Dr. Haldor Sneve, nationally known as a specialist in nervous and mental diseases and a resident of Saint Paul since 1899, died Sunday in San Diego, Calif., where he went a year ago in an effort to regain his health.

Dr. Sneve formerly was president of the Ramsey County Medical Society, the Minnesota Academy of Medicine and the Minnesota State Medical Association, and in addition to holding numerous other offices in medical organizations during his career, he was president of the Town and Country Club, Saint Paul, at the time he went to California. Golf was his hobby.

He is survived by his widow, who made the journey West a year ago and was with him at the time of death.

Dr. Sneve came to Saint Paul in 1899 from Minneapolis, to become chief surgeon of the Chicago Great Western Railroad, a post which he held for thirteen years. He was a lecturer on mechanotherapy at the University of Minnesota from 1896 to 1899 and clinical professor of mental and nervous diseases from 1911 to 1914.

He was born in Albert Lea, Minn., October 27, 1865, and

attended public school there. He was graduated from the Medical College of Ohio in 1887 and started his professional career as assistant surgeon in the National Military home at Dayton, Ohio, the same year.

From 1888 to 1890 Dr. Sneve was assistant superintendent of the Dayton, Ohio, hospital for the insane. He was the author of numerous medical papers and a member of many medical and scientific societies. He married Miss Katherine Stickney in 1897.

Dr. Sneve was a member of the Minnesota National guard for three years and served on the draft board during the World War.

REPORTS AND ANNOUNCEMENTS OF SOCIETIES

IMPRESSIONS OF THE CHICAGO SESSION

The seventy-fifth annual session of the American Medical Association which was held in Chicago, from June 9th to June 13th, was a memorable one from several points of view.

First, it was credited with the record attendance, the total registration being 7,819. The largest previous registration was 6,446 at the last meeting held in Chicago in 1908.

This session also marked an epoch in the history of the association, it being the twenty-fifth anniversary of the beginning of the organization of the medical profession through uniform county and state associations which in turn became the component parts of the great American Medical Association. Meanwhile the membership has grown until it has reached the grand total of over 90,000.

Through the genius, foresight and executive ability of Dr. George H. Simmons, this movement was started when he became editor and business manager of the Journal of the Association in 1899. The present form of organization was completed and put into operation at the St. Paul session in 1901.

And now that Dr. Simmons has lived to witness the full fruition of his plans, with the establishment of the association in its own home at 535 North Dearborn St., it was indeed a fitting tribute that on his retirement from the heavy burden of his position he was tendered a testimonial dinner at the Congress Hotel on the evening of June 9th, at which in the presence of more than 400 fellows he was presented with a life-sized portrait which will ultimately be placed in the building of the association.

This meeting was presided over by Dr. Harvey Cushing, of Boston, and addresses were made by Drs. Cushing, Frank Billings, W. J. Mayo and Mr. Will Owen Jones, editor of the Nebraska State Journal. The portrait of Dr. Simmons was presented by Dr. William S. Thayer, of Baltimore, to which Dr. Simmons responded briefly but appropriately.

The meeting place in the new municipal pier, on the lake front, was an innovation and was, in most respects, a successful experiment. The ample space available made it possible to house everything under one roof. This furnished ample space for registration, for the commercial and scientific exhibits, and also made possible the housing of the various sections of the scientific assembly close together so

that one could readily go from one section meeting to another without loss of time.

There were two serious drawbacks, however, to this arrangement. The temporary division of the space in the great pier to accommodate the various sections left much to be desired in acoustics, and the very general custom nowadays of those presenting papers to demand facilities for lantern demonstrations, if only for the exhibition of a few tables of figures, made it necessary to board the room on all sides, rendering it dark, barn-like and unattractive in appearance, and impossible of ventilation. For this last inconvenience, fortunately, the weather was cool. These disadvantages, however, were of minor importance as compared with the many advantages.

The scientific exhibit was perhaps the best and largest ever shown and there were 140 individuals who participated. An interesting feature, and one that was most popular with the visiting doctors, was the daily demonstration of fresh pathological material received from the Chicago hospitals and the Bureau of Animal Industry at the stockyards.

The opening of the general meeting was held Tuesday evening, June 10, at the Auditorium Theater, at which time President-elect Dr. William A. Pusey read his presidential address, which appeared in the *Journal* June 14th.

The officers elected for the ensuing year were as follows: President, Dr. William D. Haggard, of Nashville, Tenn.; Vice-President, Dr. E. B. McDaniel, of Portland, Oregon; Secretary, Dr. Olin West; Treasurer, Dr. Austin A. Hayden, of Chicago; Speaker of the House of Delegates, Dr. Frederick C. Warnshuis, of Grand Rapids, Mich.; Vice Speaker, Dr. Rock Slyster, of Wisconsin.

Two members of the Board of Trustees, Dr. Wendell C. Phillips and Dr. Frank Billings, declined to be candidates for re-election and the vacancies created by their retirement were filled by the election of Dr. J. H. Walsh, of Illinois, and Dr. Edward B. Heckel, of Pennsylvania.

Dr. Thomas McDavitt, whose term of office also expired, was unanimously re-elected.

With the retirement of Dr. George H. Simmons from active participation as editor of the *Journal* and general manager, there will be little change, as Dr. Fishbein, who succeeds him as editor of the *Journal*, has been in training for the position for some time. The same may be said of Dr. Austin A. Hayden, who is to become business manager. It is a source of satisfaction to know that the valuable services of Dr. Simmons will still be at the disposal of the association in an advisory capacity.

The meetings of the House of Delegates and of the various committees were held in the Association Building at 535 North Dearborn Ave., 132 delegates out of a total of 150 being registered. In the prompt transaction of business the house made a record and this was largely due to the ability of its speaker, Dr. Frederick Warnshuis, and the indefatigable efforts of our very able and efficient secretary, Dr. Olin West. Familiarity of the delegates with the business to come before the house also facilitated greatly the transaction of business.

State associations are coming to realize more and more the necessity of exercising great care in the selection of the delegates to represent them, and it is a common custom to return a delegate who has rendered conspicuous ser-

vice, for a second or even a third term. It is a matter of record that it requires one term for the new member to become acquainted with the business before the house and to get his bearings. For the first year he is assigned no committee appointment, and perhaps only a minor one the second year, and it is the members of committees who do the work. Therefore, the new member has little more than the privilege of a seat and vote. Our policy of promoting alternates to succeed to delegates does not meet the requirements, as the alternate does not attend the meetings, except in the absence of the regularly elected delegate. It is a great honor to be selected to represent the association in the House of Delegates, second only to the presidency of the association, but instead of passing the honor along to members of our association whom we wish to recognize, would it not be well to look particularly to his qualification, his interest in the association, his familiarity with the working of the organization, and then if he makes good to continue him in office for at least a second term?

According to the recommendation of the House of Delegates, if the Board of Trustees adopts the reapportionment plan, Minnesota will have three members in the next House of Delegates.

Invitations from three cities were reported by the Board of Trustees for the next session, Atlanta, Georgia, Atlantic City and St. Paul, Minnesota. A majority of the House of Delegates expressed a preference for Atlantic City. Final choice of time and place of meeting will be decided upon by the Board of Trustees.

LYMANHURST AND PARKVIEW STAFF MEETING

The regular monthly meeting of the Lymanhurst and Parkview medical staffs will be held at the Lymanhurst School, 1800 Chicago Avenue, Minneapolis, Tuesday evening, July 22, at 7:00 o'clock.

The following program will be given:

"X-ray Findings and Significance of Different Types of Tuberculosis in Chests of Children." Dr. Russell Gates.

"Roentgenologic Distinction Between Tuberculous and Non-Tuberculous Diseases of the Lungs." Dr. F. S. Bissell.

"Roentgenologic Diagnosis of Gastro-Intestinal Tuberculosis." Dr. R. G. Allison.

"Roentgen Therapy in Tuberculosis." Dr. Leo Rigler.

All persons interested in tuberculosis are invited to attend these meetings and participate in the discussions.

CONFERENCE OF STATE AND PROVINCIAL HEALTH AUTHORITIES OF NORTH AMERICA

At the thirty-ninth annual meeting of the Conference of State and Provincial Health Authorities held in Lansing, Michigan, June 16 and 17, 1924, Dr. James A. Hayne, State Health Officer of South Carolina, was elected president; Dr. B. U. Richards, State Health Officer of Rhode Island, vice-president, and Dr. R. M. Olin, State Health Officer of Michigan, re-elected secretary-treasurer.

The attendance at the conference included thirty-one state health officers, one provincial (Saskatchewan) representative and a large number of guests. Following the conference proper, members and guests were given the opportunity of studying the methods of the Michigan Health Department which is housed in the State Office Building.

"The Automobile as a Public Health Hazard" was the subject of the president's address delivered at the opening session by Dr. A. J. Chesley, St. Paul.

STEARNS-BENTON MEDICAL SOCIETY

The Stearns-Benton Medical Society held its annual meeting at St. Raphael's Hospital, St. Cloud, on April 17. Officers elected for the coming year are: President, Dr. C. B. Lewis, St. Cloud; vice-president, Dr. G. S. Sutton, St. Cloud; secretary-treasurer, Dr. J. N. Libert, St. Cloud.

OF GENERAL INTEREST

Dr. E. R. Crow, formerly of Green Isle, is now located in Minneapolis.

Dr. Ernest H. Morris, formerly of Austin, is now located in Canadian, Texas.

Dr. George A. Geist, of St. Paul, has announced the removal of his offices from West Seventh Street to 741 Lowry Building.

Dr. E. M. Hammes, St. Paul, has moved into new offices at 535 Lowry Building. Dr. Gordon B. Kamman is associated with Dr. Hammes.

Dr. W. H. Hengstler, who recently returned from California, is now associated in practice with Dr. C. E. Riggs in the Hamm Building, St. Paul.

Dr. Everett Charles Hartley has announced the opening of offices in the Lowry Building, Saint Paul, for the practice of obstetrics and gynecology.

Dr. W. P. Shepard, assistant director of the Students Health Service at the University of Minnesota, has been granted a year's leave of absence.

Dr. R. H. Kennicott is now associated with Drs. Frick and Smith, Los Angeles, California. They have recently moved into the new medical office building.

Announcement has been received of the marriage of Dr. Erling W. Hansen, of Minneapolis, to Miss Anna Ruth Eddy, Minneapolis, which took place June 4.

Dr. Louis A. Hauser, formerly of St. Paul, has entered private practice in New York City. He has also a teaching position on the Cornell University teaching staff.

Dr. Kenneth Phelps, Minneapolis, has received notification of his election to membership in the American Bronchoscopic Society, an organization of forty members.

Dr. L. W. Morsman, Hibbing, sailed for Europe on the steamship Volendam from New York, June 14. Dr. Morsman will spend a year doing post-graduate work in Vienna.

Appointment of Dr. Charles E. Proshek to the fellowship in obstetrics and gynecology maintained by the Swedish Hospital has been announced by the School of Medicine, University of Minnesota.

Dr. Andrew Sinamark, formerly of the Gifford Clinic, Omaha, is now associated with Dr. L. W. Morsman, of Hibbing, Minn. Dr. Sinamark limits his practice to diseases of the eye, ear, nose and throat.

Dr. Charles A. Reed, of Minneapolis, was a guest of the surgeons of the Great Northern railroad at their annual

meeting in Spokane, Washington, June 23 and 24, where he read a paper on "Back Injuries."

The new deep x-ray therapy equipment which Dr. Edward Schons has been installing at St. Luke's Hospital, Saint Paul, is now in operation. The apparatus includes one of the first thirty-milliampere high voltage, water cooled Coolidge tubes to be installed for clinical use.

Dr. and Mrs. John F. Fulton, Saint Paul, sailed last month for England, where they are the guests of their son and daughter-in-law, Mr. and Mrs. John F. Fulton, Jr., who make their home in Oxford. Dr. Fulton will return to Saint Paul the middle of this month. Mrs. Fulton expects to spend the entire summer abroad.

Physicians from thirty-six communities were registered at the Medical Short Course at the University of Minnesota, which was recently brought to a close. Fifteen were from Minnesota, seven from Iowa, six from North Dakota, and one from Wisconsin. A second medical short course of two weeks will be conducted in September according to an announcement made by R. R. Price, director of the General Extension Division.

Public Health Summer Schools are being conducted this year for the first time by the Universities of Columbia, Michigan, Iowa and California. These courses are suggested by the United States Public Health Service and offer an opportunity to those engaged in the various branches of public health work to obtain instruction in a great variety of subjects. The National Health Council has called the attention of the profession to this new departure in University summer courses.

The New Prague Community Hospital was opened to receive patients, June 9, 1924. The hospital is to be operated by a voluntary association without capital stock, and it is provided that no profit or dividend shall ever be paid to any member or individual. It is organized and will be operated solely to provide a service to the community. The operating room is thoroughly equipped and a high grade sterilizer has been installed. There is a fully equipped separate maternity department with delivery room and excellent accommodation for patients.

The distinction of having the highest rank of any student in the past seven years belongs to Miss Huldah Thelander, of Little Falls, who was a member of the graduating class of June, 1924, at the University of Minnesota Medical School.

The leading graduate student to receive the M.D. degree is Dr. Frederick C. Eberson, who has won distinction as a graduate student of bacteriology. Dr. Eberson, who came to Minnesota two years ago, has been working under fellowships granted by the Hennepin County Medical Society.

Enlargement by approximately 100 beds of the Minnesota General Hospital, situated at the University of Minnesota, was begun June 18 when steam shovels began excavating for the Todd Memorial and George Chase Christian Memorial units on the university campus. The Todd hospital will be built especially for the treatment of eye, ear, nose, and throat cases. The Christian Memorial unit will be a cancer hospital.

Dr. L. B. Baldwin, superintendent of the University hos-

pitals, expects to have the new buildings ready for use a year from September.

A gift of \$250,000 by the Citizens Aid Society of Minneapolis has made possible the erection of the cancer hospital. The Citizens Aid Society is a foundation established by the late George Chase Christian. Of the total, \$200,000 will go into the building and \$50,000 into special radium and X-ray equipment for treatment of cancer.

Gifts of \$20,000 by Mrs. Frank C. Todd, widow of the physician after whom it is named, \$20,000 by Mrs. E. C. Gale and \$5,000 by Mrs. Mapes gave the nucleus of the Todd hospital fund. The regents have added from building funds money to erect a hospital costing, with equipment, about \$180,000.

The capacity of the University hospitals is increased from 193 beds to approximately 300 beds by the additions.

By an act of the 1921 legislature the University hospitals are also the Minnesota general hospital, to which any county may send patients for care. In these cases half of the expense is borne by the state and half by the county.

Both hospitals will be built along Union Street Southeast and will be connected by a wing with the Elliott Memorial hospital, which stands on the river bank, overlooking East River Drive.

Approximately 95 physicians have been added to the rolls of medical practitioners in Minnesota by the University of Minnesota Medical School during the past year according to statistics in the office of Dean E. P. Lyon. Forty were graduated with the M.D. degree at the end of the fall quarter last December, two were added in April, and 53 more doctors were graduated June 18 at the close of the college year.

NEW AND NON-OFFICIAL REMEDIES

The following articles have been accepted by the Council on Pharmacy and Chemistry:

ABBOTT LABORATORIES:

Neutral Acriflavine-Abbott for Intravenous Injection,
0.1 gm. (ampules)

HOFFMANN-LA ROCHE CHEMICAL WORKS:

Digalen-Roche (Cloetta)
Ampules Digalen-Roche (Cloetta), 1.1 c.c.
Tablets Digalen-Roche (Cloetta)
Hypodermic Tablets Digalen-Roche (Cloetta)

LEDERLE ANTITOXIN LABORATORIES:

WILSON LABORATORIES:

Desiccated Parathyroid Substance-Wilson

Tablets Desiccated Parathyroid Substance-Wilson,
1/20 grain
Tablets Desiccated Parathyroid Substance-Wilson,
1/10 grain

NEW AND NON-OFFICIAL REMEDIES

Cryogenine Phenylsemicarbazide.—Cryogenine is an antipyretic and analgesic. It is claimed that cryogenine does not affect digestion and that it has scarcely any effect on the circulation and respiration. Cryogenine is claimed to be useful as an antipyretic in febrile conditions. As an analgesic, it is said to be of value in rheumatism, headache, sciatica, gout and in painful conditions generally. Cryogenine is marketed in the form of powder and 0.5 gm. tablets.

Neosphenamine (Mallinckrodt).—A brand of neosphenamine. N. N. R. For a discussion of the actions, uses and dosage of neosphenamine, see New and Non-official Remedies, 1924, p. 49. Neosphenamine-Mallinckrodt is marketed in ampules containing, respectively, 0.15, 0.3, 0.45, 0.6, 0.75, 0.9 and 1.5 gm.

letin (Insulin-Lilly) U-10.—Each ampule contains 40

units of Iletin (Insulin-Lilly) (see New and Non-official Remedies, 1924, p. 152). (Jour. A. M. A., May 3, 1924, p. 1443.)

Ethylene for Anesthesia.—*Aethylenum pro Narcosi.*—It contains not less than 93 per cent by volume of ethylene. Trials on human subjects have confirmed the anesthetic and analgesic value of ethylene as demonstrated on animals. Deep surgical anesthesia is stated to be produced easily and analgesia comes on readily and apparently long before surgical anesthesia is established. Given with oxygen, it has been found more powerful than nitrous oxide for animals and man, and in most cases as effective as ether. Trials indicate that ethylene is of value for the production of surgical anesthesia, and that it has advantages over nitrous oxide. Ethylene for anesthesia is supplied in the compressed state in metal cylinders. To avoid accidental explosion, ethylene must not be brought in contact with a naked flame or an electric spark. Ohio Chemical and Mfg. Co., Cleveland. (Jour. A. M. A., May 17, 1924, p. 1600.)

Desiccated Parathyroid Substance.—*Wilson.*—The exterior parathyroids of the ox, freed from fat, cleaned, dried and powdered. For a discussion of the actions and uses of parathyroid gland, see New and Non-official Remedies, 1924, p. 224. Desiccated parathyroid substance—Wilson is marketed in the form of powder and in tablets containing, respectively, 1/20 grain and 1/10 grain. Wilson Laboratories, Chicago. (Jour. A. M. A., May 24, 1924, p. 1693.)

Mead's Powdered Protein Milk.—A milk preparation having a relatively high protein content and a relatively low carbohydrate content. Each 100 gm. contain approximately protein 37 gm., butterfat 31 gm., free lactic acid 3 gm., lactose 19 gm., and ash 4.6 gm. When suitably mixed with water, powdered protein milk is said to be useful for correcting intestinal disorders of infants and children. Mead, Johnson & Co., Evansville, Ind.

PROCEEDINGS OF THE MINNESOTA ACADEMY OF MEDICINE

MEETING OF MAY 14, 1924

The regular monthly meeting of the Minnesota Academy of Medicine was held at the Town and Country Club on Wednesday evening, May 14, 1924, at 8 p. m. The meeting was called to order by the President, Dr. Hamilton. There were thirty-four members and three visitors present.

The minutes of the April meeting were read and approved.

The following case reports were given:

1. DR. A. C. STRACHAUER (Minneapolis) reported three cases of carcinoma of the rectum, with demonstration of specimens. He then presented the subject of surgery of cancer of the rectum, and showed lantern slides.

In briefly reviewing our experience in this field the following features stand out prominently:

1. The long interval of time elapsing between the appearance of the symptoms of cancer of the rectum and the time of institution of treatment. The majority of patients have not heeded or appreciated the importance of Nature's warning.

2. The long interval that so commonly obtains between

the time of the first visit of the patient to a physician on account of warning symptoms and the institution of proper treatment. Here the profession is grossly derelict. In many instances not even a digital examination is made. One of the cases here presented was treated for diarrhea, secondary to a carcinoma of the rectum that could be readily palpated, for over a year without a digital examination ever being made.

3. As a profession, we are making the mistake of regarding only patients over thirty-five or forty years as being in the cancer age. We have had a number of cases of cancer of the rectum under thirty, the youngest being twenty-six.

4. Surgery of carcinoma of the rectum has been a dark chapter attended by high mortality and morbidity and unsatisfactory after-results. The Kraske operation, with removal of the lower sacral segments, is a formidable and mutilating procedure. Bilroth, in 1896, reported 608 cases with a mortality of 53 per cent. The institution of the two-stage operation cut this mortality in about one-half. The two or more stage operation with improvement in technical details has further reduced the mortality to less than two per cent.

The posteriorly placed artificial anus is purely a matter of sentiment, and when so placed without sphincter control it is the poorest of locations. A lower left rectus anus performed with an ample loop of bowel for the accumulation of feces, with a valve opening, is nearly as satisfactory as the normal. I have one such patient of eleven years' standing who states that he has gotten along nearly "as good as before." The exercise of the voluntary control of the lower rectus muscle can be further developed and is at times of assistance to these individuals. A truss with pad over the artificial anus has been found to be more satisfactory than a colostomy bag.

Hemorrhage and infection have been the outstanding responsible factors in making cancer of the rectum so dark a chapter in the practice of surgery. Hemorrhage and shock are synonymous. Patients who have lost blood are more susceptible to the ravages of sepsis and respiratory infection and the various postoperative complications.

Dr. Coffey has developed what constitutes the nearly ideal operation in that it controls these two factors and in addition provides for the performance of the major procedure by the abdominal route, all performed under the direct vision of the operator.

An ample right rectus incision is made with the patient in the extreme Trendelenburg position.

a. The superior hemorrhoidal artery is ligated and divided just below the promontory of the sacrum, thus controlling the arterial hemorrhage of the operative field at its source instead of repeatedly dividing the terminal branches with successive hemorrhages as in the Kraske operation.

b. The major dissection is performed through the abdomen under direct vision of the operator, with complete hemostasis by ligature and suture. The bowel is separated from the uterus in the female and the bladder in the male, and the dissection carried down below the tip of the coccyx, if indicated. Opportunity for the removal of lymph nodes and perirectal fat and tissues is afforded under direct vision. The bowel is divided by the cautery, thus sterilizing the cut surfaces of the bowel. A left rectus anus with a trap

is formed and the lower portion of the sigmoid and rectum are invaginated through the anus by traction on a rectal tube fastened to the divided end of the bowel. The peritoneal floor of the pelvis is completely closed over this dissection and by drawing in the loose peritoneum from the sides of the pelvis an extra-peritoneal cavity drainage tract (the latter formed of peritoneum) is established, draining suprapubically from the region of the base of the bladder. In the female, after closure of the peritoneum of the floor of the pelvis, a post-vaginal drainage is established.

The second stage of the operation is performed after ten days, and is a quite minor and bloodless procedure, ten or twelve minutes sufficing for its performance. In the female it is not even necessary to remove the coccyx. In the male an incision is made around the anus and extended over the length of the coccyx, the latter being removed, and the rectum and invaginated sigmoid scooped out. By placing a rubber tube down the suprapubic tract on through the operative field, with its exit through the perineum, the entire operative field in the hollow of the sacrum can be washed, kept clean, and irrigated with Carrel-Dakin fluid, thus controlling the element of sepsis, hastening healing and greatly shortening the postoperative convalescence.

2. DR. A. W. COLLINS (Duluth) gave the following case report:

C. G. D., age 34, married. Born in Maine. Occupation—executive secretary. Mother died at about the age of 70, cause unknown. Father living and in fair health, age 70 or over. No family history of tuberculosis, carcinoma, insanity or Bright's disease. Patient was a healthy child until in his teens or about twenty years ago, when he was operated upon for appendicitis, at which time the wound drained for three weeks, which he spent in bed. About one week ago, while skiing down a hill, he struck against a stone fence and hurt his right side in the neighborhood of the old operation scar and had pain along the groin and down into the right cord and testicle. Two days before I saw him, in January, about one week following the skiing accident, he made a long auto trip into the country on business and became quite chilled. He complained of much pain in the right side on that day. On Sunday, the following day, January 20, 1924, he was worse and stayed in bed. On Monday, January 21st, I saw him at the instigation of Dr. Cyril Smith. I found him lying in bed in no characteristic attitude of pain; he complained of tenderness in the right abdomen and gave me the above history, also that he had had a chill on the evening of January 19th and that he had had more or less distress in urinating.

Examination: No lung involvement. His temperature on admission to the hospital was 102, and the tenderness was exquisite over the old wound, but there was no sign of fluctuation; he was also tender out in the right lumbar region. Pressure from the back forward in this region made him wince considerably. The tenderness in the right iliac region extended upward and gave considerable spasm to the muscles in the liver region. The left rectus (muscle) was not spastic. There was no resistance in the other portions of the abdomen. On careful questioning he stated that the appendix was removed at the time of his operation twenty years ago. He insisted that the operation was done by a competent surgeon in a large city, who was chief of a

surgical service, and that the appendix was removed, according to the statement of the surgeon.

The urine was scanty, very dark in color and contained no sediment. The tongue was thickly coated. The bowels had moved the day before, he having had a physic. The stereo-x-ray of the chest was negative. The throat was negative. On further examination of the abdomen a quick pressure over the sigmoid gave reflex pain in the region of the cecum. The white count was 19,000.

Diagnosis at that time: acute pelvic infection, possibly intestinal obstruction from old adhesions, possibly abscess in the pelvis.

Operation: Separation of intestinal adhesions and severing of constricting bands.

Operation findings: The cecum was bound down in the lumbar trough and adherent beneath the old appendectomy scar. It was folded on itself with adhesions, the last three or four inches of the ileum were pulled down into the pelvis by adhesive bands. The last two or three inches of ileum were constricted by bands. The gut was red, and, in spots, raw. The omentum at one spot adherent, red and thickened. No pus. No appendix. Adhesions separated and the constricted gut freed by cutting the bands.

Anesthetic: ether. Drainage by rubber tube.

Peritonitis developed rapidly and he died the following evening.

Autopsy showed: Spleen, adrenals, bladder, prostate, liver, stomach, small intestines, lungs, all practically negative. The external iliac glands of the right side very much enlarged, congested and edematous. Marked proliferation of the connective tissue below the old lateral appendectomy scar described above. This fibrous tissue in places very congested and edematous and shows slits filled with pus. Such spaces filled with pus are found between the fascia transversalis and the transversus abdominus, near to the iliac crest, and also between the anterior layer of the lumbodorsal fascia and the quadratus lumborum, near to the iliac crest.

The soft parts are very much congested, edematous and infiltrated around the right iliac crest, around its anterior part. The iliac crests are then cleaned of the surrounding soft parts and the anterior part of the right iliac crest is seen to be about one and one-half times as thick as the left one. On cut surface, the corticalis of the right iliac crest is thick, and very dense; the spongiosa is also more dense than usual. The peritoneum at the surface of this thickened bone is also more thick and tough than on the left side. No abscess is found in the bone, no sequestrum. The only observation made is the thickening of the bone, the thickening of the periosteum, the edema and fibrosis of the surrounding tissues which are in direct connection with the above described purulent fistulous tracts. No changes can be found in the other parts of the iliac bone, in the 12th rib, or in the dorsal column.

The diameter of the thigh is the same on both sides. There are no apparent wounds of the right limb, or of the anus.

The cecum was attached to the iliac fossa somewhat tighter than usual, by tough connective tissue. (The appendix had been removed about twenty years ago and no rests in the wound of amputation could be found on the cecum.)

The periosteum of the iliac bone is not loosened at any place; there are no naked and rough bony surfaces.

No perforation of the gut at any point, the gut having been filled with water to determine this.

Anatomical Diagnosis:

Status after recent laparotomy.

Status after old appendectomy.

Retrocecal chronic inflammation.

(Reactive) periostitis of the right iliac crest.

Inflammation of the peritoneum. (Peritonitis.)

Cloudy swelling of the kidneys.

Cloudy swelling of the liver.

Chronic cholecystitis.

Smears of pus of the parietal abscesses show numerous isolated gram-positive cocci and only a few short chains of streptococci, several groups of staphylococci.

Summary: This seems to me an unusual condition of infection lurking in an old drainage wound following appendectomy, 20 years ago. The lighting up probably had its origin in the "bump" against the stone fence a week before admission to the hospital and his lack of care of himself in the interim.

The obscurity was deepened by his insistence that the appendix was removed. The doubt of this still lurked, however, in the minds of consultants and myself.

3. DR. A. E. BENJAMIN (Minneapolis) reported a case of acute appendicitis, rupture, gangrenous, and intussusception.

Mrs. W., 41, married, 2 children (20 and 10). Family history negative.

Personal history: Well, except following birth of first child had pelvic peritonitis with some pelvic trouble for some time, with pain on the left side of the lower abdomen.

Symptoms: Was taken suddenly ill on the morning of the 13th, with acute gastric disturbance and soreness in the right lower quadrant. Has had paroxysmal attacks of pain with relief between. Was sent to the hospital on the evening of the 13th. Leucocyte count 16,000; temperature 99, which rose to 100 the next morning. Urinalysis: slight trace of albumen, otherwise negative.

Morning of the 14th, patient feeling very well. Temperature 100 and pulse 100. Great deal of pain upon pressure over the appendix. No vomiting. Abdomen fairly flat.

Operation: Under local anesthetic, gas and ether, median incision was made. The left ovary was found three times normal size, fibro-cystic, with left tube enveloping it and two parovarian cysts, thin-walled and containing about an ounce of serum. The outer half of the tube and the ovary were removed, also the cysts. The gallbladder was large, but contained no stones. It was somewhat prolapsed.

The appendix was acutely inflamed and two and one-quarter inches long, not diseased at the outer half. The base of it being surrounded by inflammatory bands and the cecum creeping upon the lower third of the appendix, the base being inverted somewhat. The cecum around the base of the appendix was very much thickened and inflamed. The ileum was kinked somewhat. This whole mass was telescoped into the ascending colon, which was redundant, showing a definite beginning of intussusception. A few bands were beginning to form, holding it in this position. This was reduced as well as the base of the

appendix, gently pulling out all the surrounding cecum. The appendix had ruptured at the base, but the imbedded condition prevented the pus escaping before operation. The base was entirely gangrenous as well as a part of the cecum. The appendix was removed and this portion of the cecum involved. Supplementary sutures brought the other portion of the cecum, mesentery, appendix and omentum over the involved diseased area. A Penrose drain was left to drain this diseased area.

Patient operated upon this morning, May 14, 1924.

4. DR. A. SCHWYZER (St. Paul) gave an additional report of a case:

This case was presented before the Academy two and one-half years previously. Patient, a lady, then 69½ years old, was operated on two and one-half years ago. Cholecystectomy was done for severe cholecystitis with stones; and because there was great thickening in the cystic duct we inadvertently removed the whole of the hepatic duct. This case was then published last fall in the "Surgical Clinics of North America." We were not sure at the time of operation that we had injured the duct, but thought we had, because there was a suspicious looking cord running upward. While the assistant closed up the wound I went into the laboratory and cut the specimen open. In the wall of the cystic duct we noticed a little tube. A frozen microscopic section showed epithelium. The shape of the tube showed that the upper end was near the bifurcation. We had not only removed part of the hepatic duct, but had removed every bit of it. The wound was amply drained. I went in again after six days, which I thought would be just long enough to have the effect of the operation overcome and short enough so that I could still open the wound easily. We found back of the duodenum and covered by fibrin, the tied-off common duct. On the liver there was the raw surface from the cholecystectomy and no sign of the duct. However, we found a little catgut on a small cord and hoped that was where we tied the duct. We loosened that ligature and it started to pump; it was the cystic artery. No place could be made out on the surface of the liver where the duct should be. But mopping carefully we finally saw a little oozing of bile, so we took a large uterine sound and went in. It slipped in easily toward the left, so that we knew we were in the left hepatic duct. Some bile escaped along this sound. We introduced a small catheter cut on a slant and left it there. The stump of this cystic artery was used to anchor it with chromic catgut. The lower part of the tube was also cut on a slant so as not to cause any pressure. The catheter was left long, so as to get the lower end out of and beyond the duodenum. After dilating the papilla, the tube went in easily. We could readily approximate the upper end of the common duct to the liver, but there was nothing to hold it except that cystic artery stump.

The tube was left in till now. It was thus in for two and one-half years, and the patient came to town at different intervals. Each time the x-ray picture was identical, with the tube remaining in place. She was perfectly well. I had word from her two years after the operation that she did her work and was well.

All went well until about three weeks ago, when she developed chills, temperature 103 degrees to 103½, and

she became severely jaundiced. She was brought to the city. We put her on Carlsbad, hoping for a gradual decrease of the fever. At the end of 8 days the same condition existed. From the x-ray picture it appeared that the tube was still in place. We had to remove that tube. But, perhaps, had the tube come out of the duct and was the present condition due to a stricture? When the tube was removed by nicking the duodenum and grasping the tube with a thin artery forceps, it retained the shape it shows in the x-ray picture, and was quite stiff. You see here the tube. I throw it on the table and it retains the same curves which you saw in the x-ray two and one-half years ago and which you see in the one taken immediately before this last operation. That is undoubtedly the reason why it was not passed.

In the upper opening of the tube we noticed a smeary greyish-looking material. We figured if this was pus, the tube had remained in place, as otherwise food would have washed it clean of pus. If the tube had been in place, our operation promised a good result. We thus made a smear of this material and found it to be pus with an immense amount of bacilli of hay-bacillus shape.

The patient thus had an infectious cholangitis. The chills stopped and now, after eight days, she is free from fever, sits up, and the jaundice has already nearly disappeared.

Dr. Schwyzer also showed autopsy specimen of a case of aneurysm of the uppermost part of the descending aorta, perforating in three places into the left bronchus. Case died very suddenly from hemorrhage. The posterior wall of the aneurysm had disappeared from pressure against the vertebral column. Three vertebræ had been eroded with the intervertebral cartilaginous discs protruding, as they are less readily yielding to pressure.

DR. S. E. SWEITZER (Minneapolis) then gave his inaugural thesis, entitled "Protean Skin Diseases, Including Syphilis; Lantern Slide Demonstration."

DISCUSSION

DR. C. D. FREEMAN (St. Paul): The method by which Dr. Sweitzer has made his entré into the Academy of Medicine is very commendable. When I heard he was to give a lantern slide demonstration instead of a thesis on some rare skin disease, I told him he used good judgment. To the average physician dermatology is a vague subject and an ultra-scientific paper by him before a body of general men would be similar to a surgeon, neurologist, or oculist delving into the intricacies of their specialty before a dermatological society.

He has practically made a clinical evening of it and has shown slides of cases many of you can recognize. I think Dr. Sweitzer is to be congratulated on his collection.

DR. PAUL COOK (St. Paul): I only wish to add that the change in the last twenty years has been very marked in the teaching of dermatological subjects. With the development of photography and showing of lantern slides, I think all physicians will be better trained in dermatology. Heretofore the ordinary courses in dermatology have consisted of lectures. The only way one can teach dermatology is to show patients with the disease or show lantern slides that will picture it clearly. I think in a few years opticians will develop lenses so that they will show the lesions better,

and there are great possibilities in color photography. Heretofore one had to go into the clinic and spend an immense amount of time examining patients.

The meeting adjourned.

JOHN E. HYNES, M.D.,
Secretary.

DISTURBANCES OF RENAL FUNCTION IN PERNICIOUS ANEMIA: Edward J. Stieclitz (Arch. of Int. Med. for Jan. 15, 1924) points out that in pernicious anemia there is frequently evidence of mild renal damage, manifesting itself by albumin, casts, or both, in the urine. He brings out the fact that up to the present time it has been assumed that this renal irritation or damage is the result of malnutrition and anoxemia of the kidneys, due to the anemia. However, this is by no means as pronounced in cases of secondary anemia. While admitting that the hemolytic intoxication of pernicious anemia may injure the kidneys directly, he brings out the fact that the deposition of iron in the kidneys may cause mild nephritic changes in experimental animals, and that therefore renal hemosiderosis might be responsible for the renal disturbances in pernicious anemia.

With regard to the incidence of renal disturbance, Cabot has reported an incidence of 46 per cent albuminuria in 506 cases of pernicious anemia, whereas at Johns Hopkins, in 50 cases, the incidence was 62 per cent. On the other hand, in 100 cases of secondary anemia, associated with a great variety of diseases, from the Presbyterian Hospital, Chicago, albuminuria was present in only 14 per cent. This shows a very striking difference in the occurrence of albuminuria in the two types of anemia.

The relationship between the hemoglobin content of the blood and the presence or absence of renal changes is interesting. Out of 150 cases of pernicious anemia, the average hemoglobin content was 41 per cent; the average of the albuminuric cases was 36 per cent, and for those without albumin 46 per cent.

The observations of many men as to the clinical character of the renal disturbance show that there is rather fixed low urinary specific gravity in connection with this disease, and that this is more pronounced with the decrease in the hemoglobin content of the blood. The PSP test usually shows a good output; blood chemistry usually normal, except for a slight increase in the uric acid content.

In regard to the pathologic changes, he states that these have not been as clear as the clinical changes. The study of the kidneys at necropsy has not yielded evidence of

uniform pathologic changes. However, from the protocols from the pathologic laboratory of Johns-Hopkins hospital of necropsies of 36 cases of pernicious anemia, 83 per cent of these showed renal pathologic changes. The most common and uniform finding was tubular degeneration, which occurred in 53 per cent of the cases. In 42 per cent there was a gross renal hemosiderosis. Where special study was made, microscopic hemosiderosis was found in 14 out of 15 cases.

His conclusions are that the most characteristic change in the kidney of pernicious anemia is perenchymatous tubular degeneration, whereas the second, and probably the more important, finding is the renal hemosiderosis.

Experimental studies by several men have demonstrated the fact that the iron content of various organs was definitely increased in pernicious anemia. This relative increase is most marked in the kidneys, but also very evident in the liver and spleen. It has been shown that the deposition of iron in the kidneys is practically constant in its distribution, and exists as a granular deposit in the cells of the convoluted tubules, proximals and distals. Occasionally it is also found in the cells of Henle's loop. Many observers have reported that there was no iron to be demonstrated in the glomerular space or in Bowman's capsule. The same distribution has been shown through experimental production of renal hemosiderosis. There is a great uniformity of the pathological and experimental reports concerning this. The convoluted tubule cells are almost universally conceded as being the site of secretion and deposition of iron-containing pigment or simple iron salts. It has been shown that the cases showing the largest amount of iron in the tubules had a lower hemoglobin reading at the time of death than the others. The author states that this may be explained in one of two ways: (1) Either that the anemia is the direct cause of the renal disturbance, or, (2) that at the time, the renal siderosis is most marked, and therefore the effects of the iron most conspicuous.

Experimental work on dogs, which is reported in the article, shows that simple secondary anemia alone does not cause any conspicuous change in renal function or in kidney damage, as manifested by albumin and casts, whereas an anemia with hemoglobinemia, and therefore renal hemosiderosis, leads to distinct renal damage, as evidenced by the fall in the phenolsulphonphthalein excretion and the appearance of albuminuria and casts.

Experimentation has also shown that iron, during its elimination by the kidneys, causes a fall in the rate of water excretion, and a fall in the specific gravity, indicating a diminution of all secretion at that time.

He summarizes his observations and results as follows: "It has been shown that:

- (1) Disturbances of renal function are common in pernicious anemia.
- (2) Histologic examination of the kidneys frequently discloses degeneration of the tubular epithelium.
- (3) There is a deposition of iron in the convoluted tubules of the kidneys.
- (4) Iron in such a location probably causes damage to the epithelium.
- (5) Iron in these cells inhibits the passage of water and total solids, and reduces the specific gravity of the urine.

(6) Fixation of the specific gravity and an increase of the night over the day urine volume is characteristic of the alteration of renal function in pernicious anemia. The correlation of these findings leads to the conclusion that the renal functional changes in pernicious anemia may be attributed, at least in part, to the accumulation of iron in the convoluted tubules, rather than to the anemia alone. The hemosiderosis and the resulting changes in function are so specific that one may speak of this condition as a nephritis of pernicious anemia. It is particularly interesting in view of the fact that the changes are apparently purely tubular, and result from a perverted metabolism."

THE CORRELATION OF AUTOPSIES AND CLINICAL MEDICINE IN TUBERCULOSIS: W. B. Jameson (American Review of Tuberculosis, April, 1924). The writer reports 100 autopsies made at the Hamburg (Pennsylvania) State Sanatorium for Tuberculosis.

Ten cases had not shown clinical tuberculosis. One abdominal mass diagnosed as tuberculous proved to be carcinoma with metastasis to lymph nodes. Another patient had an old mitral heart lesion and induration of the liver, spleen and kidneys. Several others showed emphysema and other changes due to inhaled dust in the coal mines. Of the 90 patients with clinical tuberculosis 28 had pneumokoniosis and emphysema, but all cases of lung tuberculosis had emphysema of the air vesicles immediately surrounding the tuberculous masses. The right heart showed changes in the cases of advanced tuberculosis. A portion of the lung is destroyed by cavitation, fibrosis or tuberculous masses and emphysema weakens the usefulness of the rest and a severe strain is put on the heart. Almost all the hearts of this autopsy series showed atrophy and there was always dilatation of the right auricle, ventricle and tricuspid opening and hypertrophy of the right ventricular wall. Again with the inability of the heart to perform its function there was general congestion with cyanotic induration of liver, spleen and kidneys. The size of the heart in this series was not reduced and averaged about 1 to 155 lbs. per body weight as compared with 1 to 162 lbs. or more as given by Piersol's Anatomy for normal hearts. Seventy-three of the 90 cases showed tuberculosis in all five lobes. In only 3 cases was it limited to one lobe. Nearly all had some grade of cavitation. Most of the cavities did not have fibrous limiting membranes. In patients whose condition had been quiescent a year or more, when activity developed and death ensued, the common post-mortem findings were lungs fibrosed at one or both apices with sharply limited cavitation and nearly all the remaining lung tissue studded with tuberculous masses varying in size from one-eighth to a half inch in diameter.

Following a hemorrhage, if there is a persistent elevation of temperature and death ensues, the autopsy is prone to show widely distributed masses of such tuberculous tissue.

The extension of lesions which occurs ordinarily a few months before death involves usually all the lobes and nearly all the vesicular lung tissue. It is surprising how small an amount of air containing lung tissue can support life. Some chests showed only a portion of one lower lobe capable of respiratory function.

In three cases of fatal hemorrhage the source of the

bleeding was as follows: In the first a wide open vessel about one-eighth of an inch in diameter was found in the wall of a cavity near the floor; in the second an aneurysm of a vessel traversing a cavity had ruptured; in the third a globular aneurysm rather more than a quarter of an inch with laminated wall and ragged opening was found.

Spontaneous pneumothorax was found in thirteen cases.

Every case showed chronic fibrous adhesive pleurisy usually greater in the posterior upper region. Sometimes its thickness exceeded one-quarter of an inch. Frequently the entire pleural cavity was eliminated.

None of the patients died soon after the pneumothorax in cases where it was recognized before autopsy.

One case of pneumothorax communicated with a lung cavity.

At 35 of the autopsies typical tuberculous ulcers were seen in the small intestines. Thirty-two showed characteristic ulcers in the colon, and in all the cases there was tuberculosis of the appendix.

One case had a 12-ounce amyloid spleen; 19 showed amyloid changes in spleen; 11 in the liver and 4 in the kidney. An enlarged painless liver is usually amyloid in cases of advanced tuberculosis. Fifty-one gall bladders showed abnormal adhesions to adjacent structures.

In all cases of tuberculosis of the intestinal tract the corresponding lymph nodes were enlarged. The peribronchial and mediastinal nodes were always enlarged but almost never softened.

ARTHUR T. LAIRD.

MERCURIC CHLORIDE POISONING: H. B. Weiss (The Arch. of Int. Med., Feb. 15, 1924), in discussing this subject, has given a very definite outline of the treatment that should be followed in the various phases seen in these cases.

Mercuric chloride poisoning cases are seen not infrequently, and the vast majority of these are among young women who have taken this poison with suicidal intent.

When this poison enters the system it is very quickly taken up, and it has been shown in his experimental animals that the mercury has been detected in the blood three minutes after a tablet was placed in the animal's stomach, i.e., when the dose of the mercuric chloride was .5 gm. per kilogram of body weight. In the smaller doses the time required for detecting it was longer.

From this it is evident that there are not any of the so-called specifics which would be of avail, and that there is nothing which can be used which would combine with the mercury to produce a non-toxic subject which can be eliminated. The action of the mercury is mainly degenerative in character, and affects especially the kidneys. The degree of degenerative changes occurring will depend upon the dosage and the duration of the intoxication. Death results from the kidney injury, although all the organs of the body are affected.

Weiss mentions that one of the most constant findings after bichloride poisoning is an acid intoxication, as evidenced by a reduction of the alkali reserve. There is also a diminution of the concentration of the whole blood chloride. You have a retention of the nitrogenous elements, such as urea nitrogen, uric acid and creatinine.

The urinary findings are significant. Albumin appears early. Soon there is a diminution in the quantity of urine, and this is often the forerunner of a complete anuria. As the quantity of urine diminishes, the organic elements increase, and casts, blood, pus cells, are frequently found. In severe cases the urine is often bloody. The most constant finding has been a highly acid urine. As the intoxication progresses all the signs of uremia may be present. Headache, coma, convulsions, are not infrequent. Generalized edema may occur.

In discussing the treatment he emphasizes the fact that it is exceedingly difficult, and that there are no so-called "specifics." The problem is how to overcome the effects of the poison, and that it is useless to attempt to counteract the metallic poison itself. The logical treatment appears then to be:

- (1) To prevent the progress of the pathologic changes.
- (2) To eliminate the toxic material as soon as possible.

The treatment is divided into several stages:

(a) As soon as the patient comes under observation a stomach tube is introduced, and the stomach is washed with 2 qts. of a saturated solution of sodium bicarbonate. This is continued until the washings return clear.

Before removing the tube, 6 oz. of saturated solution of magnesium sulphate are introduced and allowed to remain in the stomach.

A soapsuds enema is then given.

(b) To introduce alkalines in the system the patient should receive an intravenous injection of alkali as soon after the preliminary treatment as possible. Fischer's solution has been used. This consists of crystallized sodium bicarbonate ($\text{Na}_2\text{CO}_3 \cdot 10\text{H}_2\text{O}$), 10 grms., and sodium chloride 15 grms., both dissolved in 1000 c.c. of distilled water. If this is not available, a solution of 4 per cent sodium bicarbonate may be used. Ordinarily, 1 to $1\frac{1}{2}$ liters can be tolerated without any difficulty. The alkaline therapy should be continued by mouth. The method which he uses for this consists in dissolving 4 grms., or 1 teaspoonful, of potassium bitartrate, in 2 grms., or $\frac{1}{2}$ teaspoonful, of sodium citrate, in a glass of water, orangeade or lemonade. The patient receives 8 oz. of this drink from six to eight times a day from the onset. Hot packs have not been used, except in a few patients who had a complete suppression of urine.

A liberal diet is allowed, including meat, after the diarrhea ceases.

The treatment is controlled by urinalysis, and an effort should be made to keep the urine alkaline to methylene red, and keep it so.

Weiss has treated a series of 135 consecutive patients, with a mortality of less than 6 per cent. He states that the vast majority of the patients placed on this treatment do not develop any evidence of serious kidney disease except for a moderate albuminuria, which rapidly clears. A free secretion of urine is maintained. The patient usually makes a clinical recovery in from twelve to fifteen days. Examination of several of his patients a year after they were poisoned and treated, did not show any abnormality which could be connected with the poisoning.

CHILLS OCCURRING EARLY IN APPENDICITIS BEFORE OPERATION AND THEIR INDICATION OF AN OPERABLE STAGE OF PYLEPHLEBITIS: William Thalheimer (Arch. Surg., Mar., 1924). Thalheimer believes that single or repeated chills during the course of appendicitis usually denote septic thrombus formation in the branches of the portal vein. Pylephlebitis is well recognized as a postoperative complication and the author states that it may begin before operation, a chill usually accompanying the onset. If allowed to progress it gradually extends throughout the portal system and sets up multiple abscesses in the liver. These may in turn infect and cause thrombosis in the hepatic veins. From this point the process extends to the lungs, sets up pulmonary abscesses and progresses to fatal termination. In the early stages, where the process is confined to the portal system, the blood culture is negative; later, after invasion of the hepatic veins, it becomes positive.

Thrombosis may occur with any intra-abdominal focus of sepsis, as ulcerative colitis, sigmoid diverticulitis, etc., but is most common following appendicitis. It is most frequently found with the red edematous turgid type, in which the meso-appendix is also thick and edematous and should be looked for in the small radicles of the ileo-colic vein, if necessary nicking the veins with a knife to determine presence or absence of bleeding. If thrombosis is found, the ileo-colic vein should be ligated at a point beyond the thrombosed area and the diseased portion excised. The author cites three cases in which the above described procedure was followed with satisfactory results and a fourth in which permission for a secondary operation was refused which terminated fatally.

CONGENITAL SYPHILIS: PREVENTION AND TREATMENT: Stewart H. Welch (Arch. of Ped., Feb., 1924). Early invasion of the fetus by the spirochete pallida terminates in destruction of the fetus in almost every instance. Infection of the fetus after the middle of pregnancy may terminate in death. On the other hand, it is

the latter half of gestation which furnishes the living babies who are infected. In reviewing the pathology of the fetus, we find that the placenta becomes the primary focus, and that the organisms are carried to the fetus, not as in acquired syphilis, through the lymphatic system, but in the blood stream. This permits us to separate congenital syphilis from acquired syphilis and to define the former as a maternal infection of the placenta and a transmission of this infection from the primary focus to the fetus by the blood stream. This in contradistinction to the acquired form, or an infection of the primary site which becomes the focus, and the general transmission through the lymphatic system. Proper supervision is just as much a part of the treatment as is mercury. No congenital clinic is complete nor can it promise much success unless a competent nursing staff is available for follow-up visits and to maintain regularity in attendance for treatments. All standard methods of treatment have their applications. The truly specific drug is mercury. Administration by mouth given by parent or foster nurse over a period of two or three years is almost in every instance uneventful, incomplete or otherwise unsuccessful. Inunctions are filthy labels of the malady; a mother soon wearies of her irksome task, and after a short time you can feel sure she will develop inefficiency. Absorption of mercury by the skin is influenced by too wide individual variations. The only satisfactory therapy is the administration of the specific drug by the physician at regularly selected intervals. This permits frequent pediatric check as to the child's general condition, including diet, stools, and weight, and a recorded definite amount and interval of dosage, and safeguards intolerances. Any method which permits quick control, maintains the control, and tends to decrease the duration of needed administration is of inestimable value. With this conviction, the method of choice is the giving of the selected mercurial and arsphenamin intramuscularly or intravenously, and iodides when needed as an adjunct by mouth.

R. N. ANDREWS.

RONTGENOLOGISCHE STUDIEN UBER DIE PERISTOLISCHE FUNKTION DER MAGEN IM SAUGLING-SALTER UND IHRE BEDENTUNG FUR DIE ENTSTEHUNG DES HABITUELLEN ERBRECHENS: Julius Rogatz (Zeitschr. f. Kinderheil., Bd. xxxviii, s. 1-11). Rogatz defines the peristolic function of the stomach as the ability of the organ to concentrically surround and to adapt itself to the volume of its contents. In an interesting and valuable paper, he points out that this peristolic function of the stomach is present in infants, also. It is present, however, only after feeding of thick cereals. He found that a thick feeding of flour and milk became rapidly fluid in the stomach while thick potato and vegetable feedings retained their consistency in the stomach. From a series of x-ray studies of the stomach he points out that after thick cereal feedings the stomach assumes a round or oval form and is reduced to a third of its former size (i.e., when empty). The value of thick cereal feeding to habitual vomiters or babies with pylorospasm is thus placed on a more rational and scientific basis.

BOOK REVIEWS

BOOKS RECEIVED FOR REVIEW

APPLIED PATHOLOGY IN DISEASES OF THE NOSE, THROAT AND EAR. By Joseph C. Beck, M.D., F.A.C.S. St. Louis: C. V. Mosby Co., 1923. \$7.50.

As is evidenced by the title of this monograph, the author has placed before the specialist a definite knowledge of pathologic changes occurring within the respective organs.

The book cannot be considered a textbook (in fact, the author so informs us), as the contents are based entirely upon the author's personal experiences. Treatment is advocated on the basis of the respective pathologic conditions present. The book is adapted both for the general practitioner and specialist, perhaps appealing more to the latter for its concise and explicit manner of placing the subject matter before the reader.

The book is profusely illustrated and from the book-maker's art has been well put together.

TWENTY YEARS' OBSERVATION OF TUBERCULOSIS CONTROL IN MINNESOTA *

E. L. TUOHY, M.D.

Duluth, Minn.

This period includes my final year in the medical school, a period of some years devoted to public health in an outpost of the State Board of Health in Duluth, a year of graduate European study, chiefly in Vienna, in 1912, and the decade following thereafter. In this period I have had my connection with Nopeming Sanitarium, as chairman of the Tuberculosis Commission appointed by St. Louis County.

I must state that in the more recent years the problems concerned with tuberculosis have been merged into the consideration of a multitude of others customarily encountered in the diagnostic and therapeutic problems of a general clinic and hospital practice.

It may seem presumptuous to you to have me make this segmental analysis, basing it upon my own life experiences. Nevertheless, this has been a very active period in public health as a whole, and any statistical analysis of the reduction in death rate, including those from tuberculosis, will show that much has been accomplished. Presently the great problem before us is to continue the good work and to focus our attention upon the situations immediately facing us, because further declines in death rates are not likely to come as easily as is sometimes supposed.

Considering that little was done in Minnesota up to twenty years ago in tuberculosis prevention, points the obvious fact that there was much to do; that which remains to be done, even in a winning contest, will require much co-operation and foresightedness.

In 1904 it seemed to our clinical teachers that the outspoken problem in pulmonary tuberculosis was to *find the early case*, in order to cure it. The teaching of the Germans, Brehmer and Dettweiler, had borne fruit; the beacon of hope lighted and tended through years of struggle in the Adirondacks by Trudeau, had been sighted all over our land; Massachusetts, in 1898, had led the way with a state sanatorium; Minnesota was gathering plans for the institution at Walker; all were intent on breaking down the awful conviction of the average intelligent man: "Consumption is incurable." In that year of teaching, when exact and firm rules were laid down regarding the diagnostic use of tuberculin, the National Association for the Prevention and Relief of Tuberculosis was formed. Tuberculin, and with it all specifics for practical therapy in pulmonary tuberculosis, has been a failure; the National Association and its widespread branches have been a profound success.

We should record in passing that no early sanatoria got the "incipient" cases they were looking for; there were no "preventoriums" such as this institution where this meeting is held tonight, which is such a brilliant and successful example. Some of those we rounded up with ripping reactions after tuberculin took us very seriously; most of them sought medical advisors with less curiosity as to tuberculosis immunity, but better judgment as to general competency. Most cases labeled "incipient," and with "a slight touch in one apex" at home, were advanced cases when they got into the burdened institution. Non-tuberculous lesions of the lungs got scant courtesy from the general man, and the specialist even now is not free from the accusation that he is slow to consider them. In short, 1904 to 1912 was a period of rising hope on the part of doctors, but the deepest of despair on the part of patients, toward consumption; this disease provided the great predominant *fear* implanted in the minds of the persistently sick—a place now most certainly usurped by the fear of cancer. (We might well discuss in passing the grave need on the part of the medical profession of abating sense-

*Read by invitation before the medical staff of the Lymanhurst School for Tuberculous Children and the Parkview Sanatorium, June 27, 1924.

less fear. Particularly is this necessary where our well planned educational efforts yield the unhappy by-product of apprehension on the part of those who misapply our instructions or get them badly mixed up.)

The International Congress on Tuberculosis in Washington in 1908 had a most profound impression upon tuberculosis in America. From it some of us brought back some deep convictions that have meant much to the campaign in Minnesota. It is doubtful whether many states have plunged into a campaign any more heartily than did Minnesota; few states have been as rapidly or as successfully institutionalized for the prevention and care of tuberculosis. Newsholme and Koch were the outstanding figures of this congress. It may seem incongruous to mention them in the same breath; the one a statistician, the other a medical hero. Nevertheless, Koch, at the Congress, was like a general returning after a great war; his work had been done so well that even he never improved upon it; he was expected to produce a specific cure, and was never able to do it; therefore, he graced the program by his presence. Newsholme made the program. After the Russians had finished dangling their numerous medals; after the bearded French had ceased sputtering; after even the American "Billy Sundays"—each and all had ornamented the great record of the Congress—we all went home remembering chiefly what Newsholme had said, "We are checking tuberculosis in England by hospitalizing the advanced cases."

Another incident of the Congress is well worth recording. In a back recess among the exhibits were some roentgen plates from the irascible but most ingenious pioneer in roentgenology—Cole of New York. I was among the many who gave the few pictures he had a most casual glance and hastened on to a digest of the "57 varieties of tuberculin." There were indeed those present who were vehement about the preposterousness of injecting any such mechanical objective artifice into a problem that was so obviously subjective and concerned only with the diagnostician's cerebrum properly linked up with his own pet stethoscope. Now, in retrospect, it is evident that this despised artifice has become a "godsend" to clarify the many disturbing questions involved in proper and safe chest diagnosis. To it is due much of the honor of lifting the fear of tuberculosis from the souls of that frenzied fringe of humanity that is always the first

to drink in our health propaganda, and who are invariably the ones least in need of the draught. Chest roentgenology has done much more, but this is only a sketch and not a proportionate tribute.

At this point I wish you to travel in imagery to the confines of the "Kinder Klinik" near the Allgemeine Krankenhaus in Vienna. The time is April, 1912. Hamburger it was who talked when I entered the room. He was looking at a von Pirquet reaction on a child's arm, and he was putting forth dispassionately the story of "the primary lungen herd" in tuberculosis. This was my first introduction to the idea that tuberculosis was not the result of a cumulative exposure, on the same principle that one gets wet if it rains long enough on ordinary clothing. Soon thereafter I was permitted on numerous occasions to see the classical finding of "truly incipient tuberculosis" in the lungs of children autopsied under Erdheim. I became tremendously imbued with this most striking pathological entity. This explained why we did not have any "incipient tuberculosis" either in our offices or in our sanatoria at home.

The contention of only one probable infection with tuberculosis, and that in childhood, has gained American recognition very slowly. So far as I know, the pediatricists as a whole have quite accepted it; the older American internists have likely been the most skeptical. It is quite inopportune to further discuss the arguments pro and con that have been so much mooted. In like manner, it is quite useless to agitate the question relative to the relationship in childhood infection of bovine or human tuberculosis. Let us agree that no doubt adults may acquire tuberculosis freshly; let us likewise agree that the bovine bacillus may infect children; but, let us just as eagerly and willingly agree that most children now inoculated will get this insult via the bronchial tree from a human source; that tuberculous cattle are unprofitable and should be exterminated. Any pathologist who is willing to carefully autopsy the lungs of children will find, if he is willing to look for them, the single or multiple nodes, usually in the lung periphery, with regional lymph gland enlargement, the infectious tract being virtually the "chancre of tuberculosis." Reinfection is possible in any disease, but it is not likely with many infectious, including typhoid and syphilis. The idea of a single infection or inoculation with tuberculosis is not incompatible with the soundest reasoning and keenest analysis. It has

steadily driven home to us the inevitable conclusion that it is impossible to house children and open cases of tuberculosis in the same room; it is unreasonable to expect that highly virulent organisms fresh from the host in probably massive dose, will not produce an inoculative lesion that may not only check the immediate life of a child but challenge its likelihood for continued growth and existence at any time thereafter. It also focuses our attention upon the likely fact that casual inoculation in open places, where sunlight vitiates the strength of the organism, likely produces an attenuated organism vaccination that explains much of the specific immunity known to exist in the body fluids in such a large portion of the population of civilized areas.

In retrospect it is easy to see that much was accomplished by our early exhibits, featuring tuberculosis. They attracted large crowds and stimulated the interest of a great number of voluntary workers that did much to bring about favorable legislation and inaugurate the various movements that led to regional sanatoria, the employment of visiting nurses, the development of diagnostic clinics, and the other agencies now so well known. Not a few of the early local anti-tuberculosis societies formed have since disbanded, realizing that their work has been taken over fully and effectively by local health boards or those connected with county sanatoria. In fact, it is easy to see that other matters of grave interest, not excluding the studies in psychology, have taken up the attention of an intelligent segment of many of our localities, who would be more or less bored if the original though successful primary campaign against tuberculosis was continued in the same manner and with the same instruments. These changes, instead of being an evidence of early failure, have rather been an indication of the gradual attainment of the objective sought. The Minnesota Public Health Association, in greatly enlarging its scope of work, and including much effort particularly among children, has certainly made no mistake, and these departures are to be commended and encouraged for the future.

A statistical study, based upon Minnesota records, and attempted by the writer at this time, has seemed to reflect only dimly the real success of the campaign. It is well known to all of you that the general death rate of about 200 per 100,000 of population in the United States, at or about the

year 1900, has been reduced to about 100 per 100,000 at the present time. This means the saving of a hundred thousand lives in the United States yearly. According to the impression of close students of statistics, such as E. I. Lubin, this decreasing death rate will mean only one-fourth as many deaths in 1930 as there were in 1900. It begins to look, therefore, that the slogan, "No tuberculosis in 1950," may not seem impossible. In determining how we may continue to decrease the incidence of tuberculosis, we naturally fall upon the expedient of attempting an analysis of the factors involved in the known amelioration up to date. Only a few of these will be touched upon, including such matters as the virulence of the tubercle bacillus, the general resistance of our population, the influence of immigration, education, and our general standards of living. We should consider more fully just the type, size and general utility of our various sanatoria, upon which we know the greatest burden in our fight is still to rest. It must be fully apparent to those who have given the matter study, that the entire burden of the fight, however, cannot be left upon the shoulders of those conducting these institutions; it is the belief of Dr. Robinson Bosworth and of many others who are familiar with the situation, that we cannot abandon certain phases of "properly supervised home treatment." These, and many other factors, present themselves, but time will not permit their analysis.

THE PRESENT VIRULENCE OF THE TUBERCLE BACILLUS

There is an intimation that the bacillus tuberculosis, like bacillus lepra, is losing some of its virulence. This possibility can be briefly disposed of by considering the present morbidity and mortality from tuberculosis in known areas of Central Europe where careful observations have been made. The recent visit to this country of the well known pediatrician Finklestein brings to us the definite observation of a most careful man, that the increased incidence of tuberculosis in Germany has gone hand in hand with a reduction in the amount and quality of food known to be so essential to the young. This is known to be a war heritage wherever starvation is mercilessly persisting. It is even possible that this kind of temporary starvation may have a more vicious influence upon a people than the type of chronic and persistent starvation as is witnessed more or less constantly in Mexico. In that unhappy country, where a traveler notes, "Twelve

millions of them are forced at war times to go half starved, and in peace times are always underfed," it is even possible that a degree of hardness encompasses the survivors, reducing the ordinary influence of malnutrition. This is not the case in a country like Germany, where the best of public health and disease prevention obtained and the economic structure of the land was very cohesive. Hence a debacle such as now is present submits its population to a scale of living and nutrition that gives their natural immunity little chance. This thought would need far greater amplification, but I am sure that the supposed predisposition to tuberculosis of the Irish race as a whole was acquired from the experience of those hordes of Irish immigrants who came to America after the famine of 1840 to 1850. The Irish children that survived that unnecessary blight and were the parents of the next generation of Irish-Americans were the unhappy folks who gave to my own race a good name in fighting everything except tuberculosis. It wasn't the fault of the race, but the dastardly potato that refused to grow, aided by the cupidity of blundering English landlords.

THE RESISTANCE OF OUR PEOPLE

It is likely that every epoch in history has fancied that the standard of living attained has been so far out of proportion to that previously obtaining that grave fears were held as to whether it might be continued or sustained. As far as the question of feeding and resistance is concerned, it would seem difficult to ever produce a situation where fewer people were necessarily subjected to undernutrition than in expanding America. No doubt as population increases and the strife of existence becomes more onerous, we also will arrive at some such situations as have recently come to pass in countries even as well organized as England, particularly where economic stresses attendant upon unemployment arise. In fact, many observers, instead of fearing that our people are to suffer from undernutrition, rather fear a wholesale tendency to obesity and hyperpiasis, with resultant degenerative diseases hastened by too rich and too high living, and too little physical exercise!

As far as we are concerned as physicians, the obvious need is shown for us to continue our interest in everything that will keep our people properly employed, with suitable hours of working, and with a stability of existence based upon a fair and equitable relationship between the forces controlling our national resources and developing our

industries. This, in a word, calls for an intelligent interest on the part of all physicians in our civic and political growth. We are possibly inclined by nature or by social environment to constantly feel a suspicion of those striving for better hours of labor or higher wages, but it is manifestly to the advantage of general health conditions if the great force of working people not only in our cities but on our farms are prosperous and contented. It is our duty to work insofar as we can, as individuals and citizens, to bring such states about.

PROBLEMS OF IMMIGRATION

It is doubtful whether those who have recently drafted the immigration law have had in mind the possibility of temporarily shutting out from our shores those who have been recently subjected to the vicissitudes of malnutrition and starvation. While it may seem a turning of our back upon the older idea that our shores should be the haven of all those distressed, either mentally or physically, it must be clear at the present time that there are in large areas of Europe just the type of underfed and stunted children who could well in the next two decades become strong prospective candidates for active tuberculosis. This may be additional reason why the present restriction of immigration is worth while.

THE TRUE VALUE OF EDUCATION

Education is always mentioned as one of the chief advantages of our so-called "institutional care." Let us ask, how and why? It is fortunate that education has an influence in the mass that is often by no means reflected in the individual. Many animals have been trained either to trap their fellows or put them to work: witness the falcon and the elephant. A fair sprinkling of mentally alert individuals at strategic points keep a horde of near morons reasonably employed. Hence, education has a reputation far out of proportion to its real worth. Education and intelligence are confused: the one may be acquired—the other is a birth asset, compared with which all the earthly bestowals of chance or fortune are as mists before the mounting sun—a cataclysmic realization, is it not, and one we are often too slow in arriving at! As a man is born so he dies. Years of education are as surely wasted on some humans as if Michael Angelo had done his heroic tracings in the sand. Those of you who have said so much about "teaching the patient how to live," should well ask yourselves the question, "Who among those I am treating are capable

of being taught?" This answer can certainly neither be easily nor lightly given. This problem can be more clearly seen, possibly, by simply noting that it is totally impossible at the present time to give our best and most successful treatment for diabetes to the patient who is incapable of being taught. It is certainly accepted that it is impossible to treat the unteachable patient with insulin. Much time would be saved in many of our institutions and clinics if a conscientious effort would be made to find out those tuberculous patients who are fundamentally incapable of being taught. Their future control could then be determined, with the addition of such coercive measures and such restraint as would safeguard others. The rest could often profit greatly by more intensive personal training, where more time was available for them. The campaign of general education is going along splendidly, and it is doubtful whether we could improve on it much at the present time.

THE FUTURE WORK OF OUR VARIOUS SANATORIA

It is difficult for those familiar with the work done by our sanatoria to minimize their importance

in whatever success the anti-tuberculosis campaign has so far accomplished. It is likely that far too much of the burden involved has been forced upon them. Dr. Robinson Bosworth, of the State Tuberculosis Advisory Commission, has kindly provided for me the data relative to the development of our state and county institutions, and this is shown in the accompanying Chart I.

It will be noted that this list, with bed capacities, does not take into consideration certain well known private institutions and those beds that are available in conjunction with other public or private hospitals. It is likely that the number of such beds is going to increase as the rightful responsibility for the proper teaching of interns and nurses in the matter of the care of the tuberculous becomes more widely understood.

The data presented in Chart II, while incomplete and offering only a comparison between the beds discussed in Chart I, and the death rates as given by the State Board of Health, is nevertheless significant, because it is apparent that very soon, if not already, we have, in the institutions controlled

CHART I

<i>Sanatorium</i>	<i>Location</i>	<i>Date of Opening</i>	<i>Capacity</i>	<i>Increases</i>	
State Sanatorium	Ah-Gwah-Ching	Dec. 27, 1907	60	80	1910
				95	1911
				130	1913
				170	1914
				240	1915
				280	1918
				325	1923
Nopeming	Nopeming	May 22, 1912	50	225	
Otter Tail Co.	Battle Lake	Nov. 4, 1913	37	46	1915
Ramsey Co. Pavilion	St. Paul	Sept. 14, 1914	124	None	
Mineral Springs	Cannon Falls	Nov. 1915	34	40	1922
Sand Beach	Lake Park	Dec. 3, 1916	26	34	1921
Sunnyrest	Crookston	June 13, 1916	30	46	1921
Lake Julia	Puposky	June 12, 1916	27	48	1921
Riverside	Granite Falls	April 29, 1917	40	50	1920

Steele, Freeborn and Faribault Counties, opening 1925, probably.

by the State and County alone, a very close approximation of the same number of available beds for tuberculosis as the current yearly death rate. You will remember that this was a desideratum aimed at and only dimly hoped for in the earlier years of the anti-tuberculosis crusade.

CHART II

STATE AND COUNTY SANATORIUM BEDS AVAILABLE,
AND AVERAGE FOR FIVE YEAR PERIODS FROM
1905 TO 1923, WITH DEATH RATE PER
HUNDRED THOUSAND AND THE AVERAGE YEARLY DEATH RATE

	Average Beds Available	Average Death Rate Per 100,000 (All Forms)	Average Deaths For 5 Year Periods From Tuberculosis
1905 to 1910	70	106.4	2111.4
1910 to 1915	245	110.2	2368.8
1915 to 1920	627	102.09	2364.4
1920 to 1923	1100	77.76	1901.25

In the year 1921, 5,200 cases of tuberculosis were reported to the State Board of Health. In the same year there were 1,880 deaths. In 1922 the proportion was of 4,229 reports to 1,726 deaths from tuberculosis. Taking the year 1922, it will be noted that by multiplying the number of deaths by 2.5 we get a rough approximation of the number of cases reported. This is of particular interest because it was formerly much in vogue to state that for every death from tuberculosis there were five active cases preparing to die. Thus it would seem that in 1922 approximately one-half the cases were reported, which, all things being considered, is a rather fair attainment.

With a continued and successful fight, it would not appear, theoretically at least, that we should need any elaborate and marked extension in the number or size of our tuberculosis sanatoria. There is a large educational value accruing from the distribution of institutions, regardless of size, in various strategic points within the state. There remains at the present time no very large area of our state that is not fairly well represented. When some of the southern and southwestern portions of the state are better covered, we may point with pride to a splendid equipment with which to still further arrest the ravages of tuberculosis.

Chart II furnishes no convincing evidence at the present time of any exact relationship between the decline in the death rate and the building and extension of our sanatoria. Insufficient time has elapsed. In general, those writing on this subject

are prone to quote the statistics of New York City, not only on account of their striking figures but because they have had reliable vital statistics for a much longer period than most of us here in the west. Unofficially, however, it must be obvious that the present generation of children in Minnesota has been enormously safeguarded and protected by the fighting forces distributed and linked up within our state through our sanatoria. It is my belief that whatever development may come in the future, we should hold rigidly to keeping our tuberculosis clinics and our tuberculosis visiting nurses in the closest touch, if not under the same control, with our institutions. Our goal must be to have accurate registration within our district of every known active consumptive, and there is no better place for the assembling of this information than in our sanatoria. The information there collected may be freely transferred to the various health boards and to the state board of health, but the actual control, direction, guidance and supervision is obviously not so much an administrative problem as it is a personal one. Where this cannot be carried out by the patient's own physician, the nurses in connection with the tuberculosis clinics, and the doctors in connection therewith, and the institutions in which most of these patients have spent more or less time, are those best able to provide this needful and necessarily diplomatic oversight.

Dr. Lawrason Brown indicated for the American Sanatorium Association in 1920 the following standard:

"In order to qualify as a Class 'A' institution a sanatorium must have a resident physician and assistant resident physicians, one for every fifty patients up to one hundred and fifty, and then one for every seventy-five."

These quotations are simply introduced at this time to indicate that the problem before our sanatoria is something very different from simple housing. It is evident that a variety of situations is arising, and special extensions of treatment, such that no institution can afford to be without such vital and necessary hospital adjuncts as well equipped operating rooms and the best and most modern roentgen laboratories, and, if any worthwhile research is to be done, well equipped and manned pathological laboratories. Compression of the lungs, either by artificial pneumothorax or by extrapleural thoracoplasties, must be done in suitable

cases, and much of this requires not only a well balanced hospital staff but also such consulting staff appointments, that the various surgical and medical specialists needed for the proper conduct of medical treatment in an up-to-date manner will be available.

This suggests the inadvisability of the further development of small institutions needing such elaborate staffs and finding it difficult if not impossible to have them. It may even be essential in time to work out a system of co-operation and transfer between institutions, whereby those equipped for more intensive therapeutic endeavors may have an opportunity to focus upon those patients which time and experience will indicate may profit greatly thereby; some of the others might continue to carry out the less elaborate procedures.

It is increasingly more evident that even such simple procedures as the application of heliotherapy, Alpine light, ordinary sunlight, cannot be done in a hit-or-miss manner, but must be conscientiously and carefully supervised by those who know what they are doing.

It is useless for those in control of tuberculosis sanatoria to figure how a few dollars may be saved in their conduct. The monthly reports furnished by these institutions clearly indicate that the cost is now and always has been kept well within the average for our entire country. At the same time, it is never going to prove ultimately economical, and certainly not effectual, if we are to further depress our tuberculosis death rate, if the men who are willing to give their time and life work to these institutions are not properly compensated with reasonable salaries and given the equipment to work with. Let us look for a broadening of the scope of therapy within our institutions, and let us back the men up who are to bring this about. Let those of us outside the institution be willing and eager to furnish any and all consulting aid that is essential. By this harmonious co-ordination the effective work will go on.

GENERAL PRACTITIONERS OF MEDICINE MUST AGAIN BECOME INTERESTED IN TREATING PUL- MONARY TUBERCULOSIS

The whole problem of the care of these patients would be greatly simplified if the disease were not so wretchedly chronic, and, like typhoid fever, either yielded a reasonably prompt mortality or a recovery, accompanied by enough physical endurance to re-engage in ordinary occupations. It is

well known that many tuberculous patients neither get well nor die, but remain "status quo."

Dr. A. T. Laird, of Nopeming Sanatorium, has furnished the following data:

Between the years May, 1912, and May, 1924, 1,909 patients have been discharged from Nopeming Sanatorium. In tracing these it is known that 1,073 have died; 209 have moved away from the county; 408 are not to be found; 112 are said to be non-tuberculous. This leaves a grand total still living within our county of 407.

As to the present number of tubercle bacilli producers known to live within our county, the following table is instructive:

	Positive Sputum	Negative Sputum	Total
Patients now at Nopeming.	105	91	196
Former Nopeming patients	127	280	407
Reported from other sources	174	488	662
Total	406	859	1,265

Recently Dr. Robinson Bosworth and Dr. A. T. Laird have been co-operating in an attempt to evolve a plan whereby our institutional beds might be the more effectively utilized for the active treatment of those cases of tuberculosis that are likely to yield the maximum of results. It is surmised that there must be a fair number of patients of such intellectual capacity and of such physical and pathological status, as to be able, under proper supervision of visiting nurses and their home doctors, to utilize to a considerable degree "properly supervised home treatment." Dr. A. T. Laird has appeared before our St. Louis County Medical Society, and has instilled a considerable amount of enthusiasm into the members who heard him, relative to a plan to bring them into closer co-operation with his staff, with our tuberculosis clinics, and the various nurses in the field. There is presently a distinct danger of the various organizations at work "to pass the buck from one to another." It is my contention that as far as the average private physician is concerned, he has passed up almost entirely the matter of the treatment of the tuberculosis patient, and expects the sanatorium to look out for him indefinitely. This is fortunately as illogical as it is unnecessary. The same complaint has been made relative to our insane asylums and institutions for the feeble-minded, and on the whole is a reflection upon the sincerity of our fellow prac-

tioners who present an agonized protest to any suggestion of instituting various grades of "state medicine." Nevertheless this considerable segment of practice is abandoned, and the doctors furthering this plan are sincere in the belief that many well trained patients will be perfectly willing to employ their home physician and pay him for his services, *provided he shows enough interest to familiarize himself with the principles involved and proceed along with the patient in the attainment of his cure.* We may again here utilize the example of diabetes: for a patient who has had good training in dietary control of diabetes to consult a physician who is totally unversed in caloric values and manipulation is to destroy at once all confidence in the physician's advice and judgment. No matter how distasteful the *teaching features* of our professional function may be, we cannot avoid them.

It is to be hoped in our county that an increasing number of men will avail themselves of Dr. Laird's invitation to come to Nopeming, take part in clinical conferences, and become familiar in an intimate way with the actual detail of modern tuberculosis therapy. It is certain that in recent years the application of the cardinal principles of rest, food, fresh air, and, presently, heliotherapy, have been advised in an altogether too general manner; too much of the idea, "Be good and you will be happy." What is needed is some of the same intelligent application of correct principles in private practice as is now seen in our special clinics and hospitals.

Granting, however, the limits of instruction to which our kindly but busy confrères will submit, it must be convincingly evident that a very great field presents itself for the better instruction of our medical students and interns who are to be the active practitioners of the next two decades.

Dr. D. A. Stewart, the well known tuberculosis authority and medical director of Ninette Sanatorium, Manitoba, has done particularly good pioneer work in the matter of utilizing medical stu-

dents sent on from Winnipeg "for one month's residence at the sanatorium—an official part of their medical course." This has been done to a limited degree by our own state university, but our various sanatoria should arrange so that every graduating student might have at least a month or possibly more.

Interns graduating from our hospitals, with their final year of clinical work, should have their courses so arranged that part of that time might be spent in direct contact with those constantly teaching and directing this work. It would seem that very little effort is now needed to bring this about.

THE ACTUAL SUPERVISION OF EVERY KNOWN POSITIVE SPUTUM CASE

Finally, it must be quite evident that if every positive sputum case were under such supervision and control as to give him such surroundings as to make unlikely the infection of others, the control of tuberculosis should be just as sure as that of yellow fever where the mosquitoes are not allowed contact with the infected human. We would undoubtedly find that very few individuals securing this control would have it forced upon them unwillingly. Sanatorium trained physicians are always keen upon the feature of providing such opportunities for work and self sustenance as are hinted at in various "colonies" provided for that purpose. Even where this excellent development has not come about, have we not at the present time an extraordinary network of public health agencies with many visiting nurses in the field, all of whom could be readily drawn into the plan, which has for its ultimate intention, as far as tuberculosis is concerned, *to place a hypothetical cordon about the positive sputum case, rendering it easy for him to do his obvious duty in safeguarding his fellowmen?* The work necessary to bring about this next vital step is one of the most engaging problems before us.

THE DECLINE IN TUBERCULOSIS AS REVEALED BY POST-MORTEM EXAMINATIONS*

H. E. ROBERTSON, M.D.

Section on Pathologic Anatomy, Mayo Clinic
Rochester, Minnesota

During the six thousand years of written records of human events, accounts of devastating epidemics have appeared with steadily increasing regularity, and, on many occasions, with appalling results. No one single class of historical data rests on such certain foundations as the essential facts concerning these epidemics, which begin, often at accurately determined periods, increase in severity with varying degrees of rapidity until the high peak of incidence is reached, and then wane, gradually fading out into the unrecorded level of the ordinary ills and accidents which constantly afflict the human race. As the art of writing became more widespread, the waves of these epidemics could be traced with increasing accuracy to neighboring peoples along the lines of human communication, sometimes spreading with almost incredible rapidity, but always repeating the cycle of development and regression which is the predominant characteristic of all major plagues.

With the increasing complexity of international relations, the course of minor or more chronic epidemic diseases becomes increasingly difficult to trace, and only those with rapid rises, high percentages of afflicted persons and severe results, may be carefully studied as major events in history. Consequently we become prone to regard an "epidemic" as a disease that comes on fairly rapidly, reaches a clearly perceptible crest, works horrible havoc and then disappears.

In the earlier instances of such epidemics, ignorance with respect to their cause or manner of spreading, and the awful, irresistible onward march of the destructive "thing," in short, the universal mysteriousness of the whole process, justified the conclusion that only the gods or devils could have produced such absolutely inexplicable results. It was not until the latter part of the last century when the parasitic nature of most of these diseases was demonstrated, that rational study of them became possible, although it cannot be too strongly emphasized that the essential facts with respect to their

cyclic manner of occurrence had been indisputably established long before any clear conceptions of their cause had been reached.

However, it must be admitted that, with the exception of their wave-like tendencies and certain well established clinical and pathologic characters, the real nature of most epidemic, and many endemic, diseases only became known when the microscope, the culture tube, and experiments with laboratory animals revealed the true relation between invaded host and invading parasite, and that, in the short period of the last forty years, more knowledge about the behavior of host and parasite has been gained than in the entire thousands of preceding years. We now know that every form of animal and vegetable life suffers from pests and pestilences; the prey is preyed upon, and the extent of the battle of all living matter against the so-called natural forces of earth, air and water is readily comparable with, and perhaps exceeded by, the importance of the struggle against living foes of every conceivable variety and form and every possible degree of destructive power.

With this intensely rapid accumulation of facts concerning parasitology in its broadest sense, and the "close up" study which we now give to the habits of the contending agents, the salient points brought out by historical studies are likely to be ignored. We tend to disregard the past because of the partial ignorance which it so plainly exhibited, and we often appear to date history, with respect to disease at least, from a comparatively recent period. The complete acceptance of such an attitude will inevitably deprive us of a certain useful understanding about the natural laws of epidemics, which can only be gained by the consideration of diseases, not in terms of days, months or years, but of decades, generations or even centuries. Only when this historical background, reinforced by our present knowledge, is given full recognition, will some of the still numerous, unexplained puzzles concerning the evolution of parasitic disease receive a satisfactory solution.

The first fact that becomes pertinent in this connection is the ever-changing relation between all hosts and all disease-producing parasites. While the individual struggle between the lives of these contending forces may sway from side to side, now the host and now the parasite attaining the ascendancy, ultimately every such contest must end with the death of one or the other of the contestants.

*Read before the National Tuberculosis Association, Atlanta, Georgia, May, 1924.

No other solution is possible. In any single contest many factors may unite to give victory to either side: in epidemics, on the contrary, at least those attacking man, at first a group victory is achieved by the invading organism, but later, and always up to the present time, the host, as a group, has ultimately cast off the parasite and become temporarily, as a species, relatively immune and inimical to its efforts to live and do harm.

This cycle of events is so strongly evidenced in world-wide or local epidemics of acute diseases that we expect it, and we believe that this curve of evolution, including subsidence, must perforce occur even if we give little thought to the reasons for such a belief. These reasons, however, may be largely based on a study of the historical aspects of such diseases, sufficient periods of time having elapsed to enable us to view entire epidemics as entities, and to survey enough recurrences of the phenomena to enable us to establish fairly well definite laws concerning their behavior.

While the wave character of acute contagious diseases seems to be a firmly grounded principle, the same tendency with respect to more chronic or widespread affections is either not recognized at all, or the application of this law is wholly denied. This mental attitude is, of course, unreasonable and also unreasoning. Disease cycles may be very long, they may even, although probably rarely, take centuries to finish their course, but in the end the wave *must* finish its rise and inevitable fall, and the particular parasite as a group infection *must*, temporarily at least, cease to be a menace to its particular group host.

Of course, it is conceivable that the invading group might come off wholly victorious and the invaded host perish as a result. It is even conceivable that the human species may sometime be wiped out by some especially harmful form of infecting agent. Such, however, is not the teaching of evolution, or (if the word should be taboo) of history. Our vision is, unhappily, extremely limited, but so far as it can pierce the veil of the future, relying on the knowledge of the past, to that extent, we can rest assured of the perpetuity of the human race or some species closely related and developed from it. This certainly holds so far as any struggle between living organisms is concerned, even if it does not obtain in the eternal struggle against the natural forces of the universe.

But whether the human race is ultimately to de-

velop into a more complex species or is doomed to extinction, we are chiefly concerned at present with the hopes we may entertain of victory over certain of our more persistent parasitic enemies. Specifically stated, we wish to know what prospect the human race has of becoming free from the menace of smallpox, typhoid fever, measles, and the other acute infections, and whether there are any signs at present that the more chronic and hopeless sort of plagues, such as syphilis, leprosy and tuberculosis, will ever disappear.

As a general proposition, in view of the position just outlined, it can be confidently affirmed that, in the very nature of things, not only the acute contagions but also the chronic ones, if due to pathogenic organisms, must eventually entirely succumb in their struggle with man as a host. That new and more deadly parasites may take their places is not only possible but even probable, but that the particular diseases now afflicting man must run out their cycle to their own destruction seems as clear as any one fact in the history of the race. In Nature's laboratory there can be no such thing as a permanent parasitic disease.

The general argument might be easily developed in richer detail, with the citation of innumerable examples from both ancient and recent history, but my task is not now directly concerned with anything more than the bare outline of the thesis which has been mentioned. On the other hand, it is directly concerned with the evidence which may be found to show that, with the huge plague, tuberculosis, there are definite, seemingly unmistakable, signs that its menace is diminishing, and that as a pandemic the downward side of the cycle has been reached. Favoring this view, much general evidence gathered from comparison of mortality and morbidity statistics could be, and has been adduced, but I intend to confine myself to the evidence gathered at post-mortem examinations, and present facts which show a rather remarkable change in the reactions of the people of North America toward the bacillus of tuberculosis. In the routine conduct of post-mortem examinations, the lesions of tuberculosis are often among the most prominent, most easily identified, and least often overlooked. Consequently, statistics concerning them have a somewhat greater validity than many other and more obscure diseases. Hence, it is natural that all pathologists should be struck with the comparative frequency of various forms of tuberculous

infection, from the fulminating type of ulcerative pulmonary tuberculosis with pneumonia and generalized miliary distribution, to the tiny calcareous concretion in the peribronchial or other lymph nodes. So widespread has been the knowledge thus obtained by pathologists that the oft repeated statement that from 75 to 90 per cent of all civilized races show evidences after death of some sort of tuberculous infection is universally accepted. The character of these lesions has been described in rich detail, and all physicians, and many who are not physicians, have a fairly accurate conception of the manifold classes of reactions which occur between the virulent bacillus of tuberculosis and its often more virulent human host.

Our attention has thus been focused on the diagnosis, the effects and the treatment of the disease, and too few attempts have been made to detect or to measure the changes which must have occurred in the mass relations between the bacterial parasite and its human host. As has been previously emphasized, the word "must" is used advisedly. The plague is either increasing, at its peak, or on the downward side of the curve.

For the last two decades I have been deeply interested in the character and incidence of tuberculous lesions as revealed by examinations after death, and for the last five years I have received the general impression that a distinct and appreciable change is occurring in the relative percentages of the various types of the disease. This impression became so strong that I attempted to analyze a series of earlier cases and to compare them with other series of recent years. The results are shown in the accompanying tables.

In Table 1 the first column represents 250 complete post-mortem examinations from the records of the Pathologic Department of the Medical School of the University of Minnesota during the years 1908 to 1910 inclusive. These records were almost

entirely made by me or under my direction, and represent coroner's cases, cases from the City and University Hospitals, and a small proportion from private practice. All partial examinations and those on infants under six years were excluded, but with these exceptions the cases were listed seriatim. They are divided into four groups: (1) cases in which there were no demonstrable tuberculous lesions or pleural adhesions, (2) cases in which there was pleural fibrosis, but no lesions, (3) cases in which there were old healed foci, and (4) cases in which either chronic or acute, but still active, tuberculosis was present. The second column is a similar tabulation of 250 cases from the records of the same department, made by my successor, Dr. E. T. Bell, or under his supervision during the period between October 22, 1923, and April 21, 1924.

The results are striking. They show an increase of nearly 10 per cent in cases free from evidences of tuberculosis or adhesions, and a decrease of over 20 per cent in cases of active tuberculosis. In the third column are grouped 1,000 cases by percentages collected from the records of the Mayo Clinic, and representing post-mortem examinations performed by me or under my direction during the years 1922 and 1923. A still more striking decrease is seen in cases of active tuberculosis. The increase in cases of healed tuberculosis represents the results of extremely careful search for tiny lesions in each case. It is almost as significant as the cases in which there were no lesions, inasmuch as the healed foci represent increased resistance on the part of the host, and decreased virulence of the bacteria, betokening a losing fight for the latter.

To clarify this point further these three series were analyzed as to age incidence, and the results

TABLE 1

THE DECLINE OF TUBERCULOSIS AS EVIDENCED BY POST MORTEM STATISTICS

	1903-1910	1923-1924	1922-1923*
	250	250	1,000
	necropsies	necropsies	necropsies
	Per cent	Per cent	Per cent
No evidence	30.0	39.2	20.1
Adhesions	26.4	44.0	12.4
Healed tuberculosis ..	16.0	10.4	63.0
Active tuberculosis ..	27.6	6.4	4.5

* Mayo Clinic series.

TABLE 2

AGE INCIDENCE *

	1903-1910	1923-1924	1922-1923**
	250	250	1,000
	necropsies	necropsies	necropsies
	Per cent	Per cent	Per cent
Age, years	6 to 31 and 30 over	6 to 31 and 30 over	6 to 31 and 30 over

			68.75
			22.22
			77.77

* Same cases as were used in Table 1.

** Mayo Clinic series.

given in Table 2. Each of the columns in Table 1 was divided into two age periods, the first six to thirty years, and the second thirty-one years and over. Of the 26.4 per cent of cases in the first column of Table 1 with adhesions, 20 per cent occurred in the first age group, and 80 per cent in the second. This is what one would expect, namely that adult life would be more largely represented in any list of general deaths. The most important point is revealed in the last two columns of Table 2. Here only 8.5 per cent of the patients with evidences of healed tuberculosis were under thirty years, and 91.4 per cent were over thirty. This means that the younger generations are acquiring a total immunity in far greater degree than the older generations. In fact, if healed lesions are found in a parent we have some grounds for assuring the son or daughter of a relatively increased immunity in themselves.

The figures given do not constitute conclusive proof. They are from a comparatively small series, and are not far enough separated in point of time. However, they are presented for what they may be worth, with the hope that more comprehensive and more detailed statistics may be gathered, and clearer evidence adduced concerning this important question.

Non-specific Protein Therapy—The mechanism involved in non-specific therapy concerns cell stimulation. Weichardt assumes that this involves all cells. Other researches indicate that certain cell groups may be more particularly concerned. On stimulation, the cell becomes more permeable. Antibodies, enzymes, fibrinogen, etc., leave the cell. Under certain conditions a rapid destruction of organisms may take place to an extent that may overwhelm the patient by sudden liberation of toxic bacterial products. The first phase of the reaction corresponds in many ways to a parasympathetic effect. Later a second phase follows during which the patient is improved. This phase may exist for a considerable time and is clinically apparent in the improvement of the patient. No cases are reported in the literature in which chronic urticaria has been so treated although many related conditions on evident or probable sensitization have been improved (hay-fever, asthma, migraine, epilepsy, intermittent hydrarthrosis). Great caution must be used in the employment of the more active substances such as typhoid vaccine, peptone and collargol. Very small doses of relatively mild activity (tuberculin, casein, turpentine) are much more suitable. This has been the experience in chronic arthritis. The dosage must be adjusted to suit the patient, care being taken to keep the dose at all times just below that which causes a focal reaction at the site of the lesion. (Jour. A. M. A., June 7, 1924, p. 1883.)

FOREIGN BODIES IN THE ESOPHAGUS AND AIR PASSAGES*

PORTER P. VINSON, M.D.

Section on Medicine, Mayo Clinic

Rochester, Minnesota

On May 11, 1898, Dr. Algernon Coolidge, Jr., removed a portion of a tracheotomy tube from the right bronchus of a man by enlarging the tracheotomy wound, inserting a urethral speculum, and grasping the foreign body with alligator forceps under direct vision from a light reflected by an ordinary head mirror. This seems to be the first time that such a procedure was accomplished in this country. Since then many instances of the successful removal of foreign bodies from the food and air passages have been recorded in the literature, and, through the untiring efforts of Jackson, Mosher and many others,¹ peroral endoscopy has taken its place in the front ranks of technical surgical procedures. Because of the very technical nature of these cases, physicians have not given them much consideration, and it is my purpose to present some of the problems concerning this type of work.

Foreign bodies in the esophagus are less common than in the air passages. Coins, open safety pins, bones, partial or complete dentures, and fruit seeds of various types, may become lodged in the esophagus, but most small substances pass into the stomach without difficulty, and after entering the stomach almost all of them will have an uninterrupted passage through the gastro-intestinal tract. Often an open safety pin will pass through the entire alimentary tract of a very small child without producing the slightest discomfort. However, when one of these substances becomes impacted in the esophagus, it usually produces great discomfort, and occasionally death. At first there may be substernal discomfort with obstruction to the passage of solid food, and sometimes even of liquids. Pain on swallowing is commonly noted. If the patient strains very much to dislodge the foreign body, very early perforation may occur, with resulting mediastinitis and death.

Ulceration of the esophagus will result from the presence of almost any type of foreign body, and it is remarkable that the endoscopist rarely sees a

*Read before the Southern Minnesota Medical Association, Mankato, May 19, 1924.

foreign body that has been present in the esophagus for a long time. Stricture of the esophagus occurs rarely as a sequela even if there is considerable ulceration at the time the foreign body is removed.

Fig. 1 (A439921). An open safety pin in the esophagus that later passed into the stomach and through the alimentary tract without inconvenience to the patient.

The diagnosis of a foreign body in the esophagus can be made on the history, the direct *x-ray* findings in case the foreign body is opaque to the ray, the indirect *x-ray* findings in case the foreign body is non-opaque to the ray, and esophagoscopy. The history is quite important, and one should always bear in mind the fact that many psycho-neurotic patients have a feeling of a "lump in the throat," and will sometimes swallow a substance that produces a slight trauma in the throat and gives the sensation of a foreign body. Such patients should not be esophagoscoped unless absolutely necessary, because the trauma incident to an esophagoscopy has a tendency to increase the discomfort. In the case of foreign substances not opaque to the *x-ray*, the cause of obstruction in the esophagus may be determined by the ingestion of a thick barium mixture, or a capsule filled with barium or bismuth, and fluoroscopic examination. With the esophagoscope, the foreign body can be definitely located and its removal is usually accomplished easily.

Foreign bodies are lodged in the air passages rather often, owing to the fact that any substance

that enters the larynx will be aspirated, and unless coughed out, will remain in the trachea or one of the bronchi. Many foreign bodies are probably coughed out, but one is never justified in awaiting this method of removal. The practice of inverting the patient in an attempt to accomplish such a result should be discouraged, because a dislodged substance in the air passages may thus become impacted between the vocal chords, necessitating an immediate tracheotomy to prevent suffocation.

The symptoms of a foreign body in the air passages depend on its size, shape, composition, consistency and location. I shall not attempt to discuss the many problems involved in the diagnosis and localization of a foreign body that has been aspirated, but the combined efforts of the roentgenologist, internist, and bronchoscopist are often required.

Any child who develops an unexplained cough, with or without fever, should be suspected of harboring a foreign body in the air passages, and should have a most careful history and examination. Any patient, child or adult with a chronic pulmonary suppuration or pulmonary hemorrhage may have a foreign body in the air passages as the etiologic factor. In considering lung abscess and unilateral bronchiectasis, the presence of a foreign body should always be considered.

Fig. 2 (A455753). Ulceration caused by safety pin impacted in esophagus.

Many of the distressing results incident to the aspiration and swallowing of harmful foreign substances could be prevented by more careful oversight of children on the part of parents or attendants. This is particularly true with regard to the aspiration of peanut kernels. Small children

should not be allowed to eat nuts, particularly peanuts, as the symptoms caused by the inhalation of this type of foreign body are of a most fulminating character.

Although there are many cases of foreign bodies in the esophagus and air passages, there are hardly enough to permit the thorough training of many men for this type of work. Not more than two endoscopists to a community should be encouraged, and all cases should be referred to them so that they may perfect the technic that is so necessary

Fig. 3 (A457485). a. Nail removed from bronchus. Fever continued. b. Two weeks later, portion of oxidized metal coughed up by patient. Uneventful recovery.

in this exacting specialty. More than two specialists in this field divide the work so that none becomes expert, and the patient necessarily suffers.

Exploiting the Cancer Sufferer.—The week of the annual session of the American Medical Association was chosen as a propitious time to resurrect two discredited cancer cures. A Philadelphia paper announced that the cause of cancer had been discovered and that a treatment had been evolved which was producing remarkable results. The publicity dealt with the alleged cancer serum of T. J. Glover of Toronto. This received some attention in 1921, but was not shown to be of value. The second "cancer cure" to be resurrected was that of Dr. Wm. F. Koch of Detroit. Koch's nostrum was brought to the attention of the newspapers of the country by one C. Everett Field. It received some attention in 1921, and was reported on unfavorably. The new publicity given to these two discredited "cures" is producing the usual effect. Sufferers from cancer both directly and through their physicians are frantically trying to learn whether there is any warrant for the claims so widely broadcast. (*Jour. A. M. A.*, June 21, 1924, p. 2054.)

ETIOLOGY OF INTESTINAL OBSTRUCTION *

E. MENDELSSOHN JONES, M.D., F.A.C.S.
St. Paul

Intestinal obstruction is one of the most serious conditions with which the medical man is confronted, and in spite of the progress made in recent years, in medical science, it still presents many problems that are difficult to solve.

There are numerous factors that enter into the etiology of intestinal obstruction. There are a great many over which we have no control, but there are certain types of obstruction that occur following abdominal operations that can be eliminated if our patients are carefully prepared and we are careful in the handling of the viscera during the operation. There are some writers that believe that practically all cases of post-operative obstruction are preventable, but this view is undoubtedly too broad, for in the hands of the ablest operator, when the finest of technique is employed and the greatest of care is exercised in every respect, the fact still remains that post-operative intestinal obstruction does occasionally occur. Considering the number of abdominal sections that are performed it is striking to note the comparative rarity of post-operative ileus. It develops frequently in the most favorable cases, and at times one would least expect it, and therefore we must always be on the lookout for this complication as it is one condition above all others where every hour's delay is very costly to the patient.

I have divided the subject into four groups:

1. Cases in which the acute obstructive symptoms come on suddenly without previous symptoms;
2. Obstruction due to foreign bodies;
3. Obstruction due to tumors of the intestine, or growths outside the bowel;
4. Post-operative obstruction.

The first group I wish to consider includes the cases in which the acute obstructive symptoms come on suddenly without previous manifestations, as for example volvulus, intussusception, mesenteric thrombosis, strangulated hernia, or some form of obstruction due to a Meckel's diverticulum. De Quervain states that in most countries neither the student, nor surgeon, sees many instances of volvu-

*Presented in symposium on Intestinal Obstruction at St. Paul Clinic Week, January, 1924.

lus, but in Russia, especially in the Baltic states, it is the most frequent variety of obstruction brought into the hospital. Various explanations have been offered for this: the abundant dietary of potatoes or the greater length of the Russian intestine. These views are not accepted and it is much more likely that volvulus is due to a congenital or acquired abnormality in the mesentery, such as a long mesentery with a narrow attachment, thus affording the mesentery a more extensive movement. A volvulus may also be produced by the rotation of the ileum about its mesenteric border because of the lever action of a distended Meckel's diverticulum.

Intussusception may occur when an inverted diverticulum becomes invaginated into the ileum, forming a starting point for a progressive intussusception. An adherent Meckel's diverticulum may act the same as an adhesive band and cause strangulation of a loop or loops of intestine that might be caught beneath it.

When any of the external hernia, such as the inguinal, femoral, umbilical or ventral, become strangulated and the sac includes one or more loops of intestine, an acute ileus occurs. Forcible reduction of a hernia frequently leads to traumatism of the contents of the sac and adhesions occasionally result which may lead to the development of an obstruction. In this obvious type of hernia the solving of the problem is not as difficult as that presented by the strangulation of an internal hernia. Strangulation of an internal loop into a congenital peritoneal pouch is one of the rare causes of intestinal obstruction.

The principal forms of congenital internal hernia are: hernia at the foramen of Winslow, duodeno-jejunal hernia, hernia into the ileo-appendicular or retro-cecal pouch, and diaphragmatic hernia.

Embolism or thrombosis of the mesenteric vessels gives rise to a very fatal type of obstruction. It comes on suddenly and in its onset often resembles a paralytic ileus. The portion of bowel that has its circulation interfered with undergoes paralysis and this is rapidly followed by gangrene and peritonitis. Mesenteric embolism or thrombosis is apt to occur in cases suffering from valvular disease of the heart, or cases that have had an ulcerative endocarditis.

In the second group are the cases in which the occlusion of the bowel is due to a foreign body.

The most common causes of this type of ileus are gallstones and fecoliths. Obstruction due to true fecoliths is not common. Fecoliths are formed by the deposit of earthy salts around some foreign body matrix such as a fruit stone or a large vegetable fragment. This type of mass may be found in the colon or the ileum. Gallstone ileus is not common when one considers the frequency of obstruction due to other causes. The most common mode of communication is through the formation of a gallbladder-duodenal fistula. The stone being too large to pass out through the ducts, sets up an irritation which continues until a localized peritonitis results, which naturally causes adhesions to form with the adjacent structures, most commonly the duodenum. The continual pressure of the stone then leads to a fistulous opening into the first or second portion of the duodenum. If a stone is less than one inch in diameter it usually passes through the intestinal canal without causing obstruction. Even though the mass is large enough to cause a complete obstruction, there usually are intervals during the attack in which there is a cessation of the severe symptoms. These are due to the stone, through some means, being dislodged and to the fact that it makes some progress in advancement. The quiescent period lasts until the stone is again arrested in its progress and the strong peristaltic action begins an effort to expel the foreign body. This phenomenon may occur several times before the stone reaches its final goal, either of impaction or spontaneous expulsion. The occlusion of the intestine is not only due to the size of the stone but also to a spasm of the circular muscular fibers of the intestine. At autopsy in these cases decubital ulcers are found in the intestine, indicating the different points at which the progress of the stone was checked. When the obstruction is complete the distention of the bowel causes a perforation of one or more of these ulcers and peritonitis follows. Early peritonitis accompanies gallstone ileus more frequently than obstruction from some other cause and it undoubtedly plays an important rôle in the mortality.

The third group of cases includes those in which the obstruction is due to tumors of the bowel or to occlusion of the gut by pressure from a growth outside the bowel. Tumors are found more often in the colon than in the small intestine. They may cause obstruction by blocking the intestinal canal or by causing a kink in the bowel. Not infre-

quently they are the primary cause of a volvulus or intussusception. The benign tumors that occur in this region include adenoma, fibroma, lipoma and myoma, and the malignant tumors are carcinoma and sarcoma.

Carcinoma is the most common malignant tumor found in the intestinal tract and occurs more often in the colon than in the small intestine. Malignant tumors cause obstruction more frequently than the benign growths. Tuberculosis of the intestine may give rise to a chronic incomplete obstruction and at any time an acute complete ileus may develop.

Interference with the lumen of the intestine due to pressure from a tumor outside the bowel does not usually occur until the tumor is obvious or palpable. In this group may be mentioned the retroverted pregnant uterus, enlarged spleen, tumors of the uterus, ovaries or mesentery. The obstruction usually occurs in the rectum, the sigmoid flexure, or the colon above the sigmoid.

The fourth group includes cases of post-operative obstruction. In this group the type that is perhaps as puzzling as any other is that of paralytic ileus. This is due to a paralytic distention of the bowel caused by undigested food contained in the intestine or to traumatism of the intestines or mesentery during the operation. It is also often associated with an acute local or general peritonitis or an acute pancreatitis.

Post-operative adhesions resulting in bands that constrict the intestine or adhesions that form in such a way that the intestine becomes kinked, account for the majority of post-operative obstructions. If a patient has had an abdominal section and signs of acute intestinal obstruction present themselves, in the majority of cases, a band will be found to have caused the obstruction. The question of post-operative adhesions is a most important one and if some one could tell us how to absolutely prevent them it would be a great contribution to the science of surgery, but as far as I have been able to ascertain no satisfactory solution has as yet been advanced. These adhesions may form bands that are circumscribed and cut off the intestinal lumen or, frequently following the freeing of inflammatory adhesions, loops of intestine again become adherent and because of the inflammatory reaction and associated edema an obstruction may develop. This type of ileus may follow operations on the gallbladder, stomach, intestines, pelvic organs, or simple separation of adhesions due to

previous inflammatory diseases or operations. The surgeon has practically no control over the causative factor in this type of obstruction, but I wish to mention a few examples of post-operative ileus in which the surgeon does have the prevention in his own hands.

In doing a gastro-enterostomy an operator may not be careful in bringing up the loop of jejunum and in his manipulation this loop may become twisted, thus causing an interference with the intestinal lumen, and an obstruction results. Failure to suture the mesocolon to the stomach in doing a posterior gastro-enterostomy has often in the past been the cause of obstruction, as there is a tendency for the stomach to draw the jejunum upward through the opening in the mesocolon and strangulation of the loop of jejunum frequently follows. When performing an operation for suspension of the uterus in which the round ligaments are brought through the abdominal wall, great care should be exercised that no opening is left between the parietal peritoneum and that portion of the ligament between the internal ring and the point where the ligament is drawn into the abdominal wall. After the sutures have been placed, anchoring the ligaments to the fascia, one should again examine the ligament to be sure no space is left above the distal portion in the abdomen. Any opening at this point is a most favorable place for a loop or loops of intestine to enter and under various circumstances a strangulation may occur and an obstruction will result.

Not infrequently in dealing with the omentum it may be perforated in one or more places. It is obvious that such a condition invites trouble, as a loop or loops of intestine could very easily pass through one of these openings and one can readily conceive an intestinal obstruction as a result.

From these few examples it is evident that the surgeon must pay as much attention to the little things in surgery as he does the very evident major problems.

Intestinal obstruction is primarily a surgical condition, but since the successful therapeutic management of any disease is directly dependent upon the degree of familiarity with the etiological factors of the disease being treated, and since the internist is usually the first one that comes in contact with these cases, it behooves him as well as the surgeon to be thoroughly familiar with intestinal obstruction and its etiologic factors.

Van Buren, in a recent article on acute mechanical ileus, makes the following statement: "Subject to certain exceptions, it might be stated as a corollary that, if the case is really one of acute mechanical ileus, the longer the patient lives with it before operation the sooner he dies afterwards."

Dose of Thyroid for Children.—Thyroid effects are generally obtained by the administration of Dried Thyroid U. S. P. (Thyroideum Siccum). There is, however, no fixed dose of thyroid for children. The amount of dried thyroid to be administered must be determined in each case. A safe initial dose for a child three years of age would probably be 0.015 gm. of dried thyroids two or three times a day. The best way is to start with a small dose and to gradually increase it until either satisfactory improvement or symptoms of intolerance manifest themselves. As soon as the desired effects are obtained or symptoms of intolerance manifest themselves, the dosage must be reduced. (Jour. A. M. A., June 21, 1924, p. 2070.)

Therapeutic Lamps.—The Kromayer water-cooled mercury-quartz light and the Burdick and Hanovia mercury-quartz lights are considered sources of ultraviolet radiation of strong intensity, emitting a large quantity of long and short ultraviolet wave lengths. In contrast to this, carbon arc lamps, of which the ultra-sun lamp is an example, are used more particularly for the rays present similar to those in the spectrum of sunlight; namely, the invisible heat rays, the visible rays and the longer ultraviolet rays. The non-burning feature of the ultra-sun lamp is due to the practical absence or very weak intensity of the short ultraviolet rays which are the wave lengths that irritate and easily produce an erythema. The advertisers of the ultra-sun lamp stress the fact that the spectrum of their lamps is a continuous one, whereas the spectrum of the mercury-quartz light has gaps. No one has yet proved, however, that the presence of gaps in a spectrum is a drawback in the clinical use of that light. Furthermore, no one has proved that the burning or erythema-producing rays of the mercury-quartz lights are disadvantageous. It cannot be said that the carbon arc lamp is less valuable than the mercury quartz lamp for certain diseases. The exact indications for the different sources of light have not been worked out. (Jour. A. M. A., June 28, 1924, p. 2138.)

Vehicles for Prescriptions.—The following is a list of vehicles that can be used to prepare pleasant tasting mixtures: Aqueous Elixir of Glycyrrhiza N. F., Compound Elixir of Cardamom N. F., Compound Elixir of Almond N. F., Compound Elixir of Vanillin N. F., Glycerinated Elixir of Gentian N. F., Elixir of Anise N. F., Red Aromatic Elixir N. F., and Compound Syrup of Asarum N. F. The formulas of these preparations may be found in the Epitome of the U. S. Pharmacopeia and National Formulary, published by the American Medical Association. (Jour. A. M. A., June 28, 1924, p. 2138.)

SURGICAL DIFFERENTIAL DIAGNOSIS OF ACUTE INTESTINAL OBSTRUCTION*

F. J. PLONDKE, M.D.

St. Paul

The course of acute intestinal obstruction is rapid; if unrelieved the mortality is 100 per cent. When it has reached the stage of easy recognition the case is often hopeless.

I believe that I speak for every surgeon when I say that we would infinitely rather meet in consultation the practitioner who, early in the case, contents himself with something having gone seriously wrong in the abdomen than the one who 48 hours later will give us an accurate description of what the operation (or post-mortem) will reveal.

The symptom complex of acute intestinal obstruction resembles very closely that of other conditions coming under the head of acute abdomen or abdominal crises. It is therefore not always easy to differentiate.

In attempting a differential diagnosis it is well to remember that pain resulting from a lesion of a viscus is felt, not in that viscus itself but is referred to the peripheral distribution of the spinal nerves arising from those segments of the cord with which that viscus is connected through its sympathetic nerve supply. So far as the alimentary canal is concerned, reflex pain from the stomach is referred to the region of the xiphoid cartilage and the umbilicus; that from the small intestine and appendix to the umbilical area, and that from the large intestine to the mid-hypogastric line. From the liver, gall-bladder, and bile ducts, pain is referred to the lower part of the epigastrium and also sometimes to the lower angle of the scapula.

All pain, therefore, that is felt in the early stages of an acute abdominal crisis is of this reflex character and is not localized to the situation of the viscus primarily at fault. Later, when the local inflammation has developed sufficiently to irritate the parietal peritoneum, the pain becomes localized at this point.

The number of conditions which might at some stage simulate intestinal obstruction are so numerous that it would be impossible in the time allotted to even hint at how they could be recognized either preoperative or post-mortem. The more common

*Presented in symposium on Intestinal Obstruction at St. Paul Clinic Week, January, 1924.

are general peritonitis, acute pancreatitis, acute appendicitis, acute perforation of gastric or duodenal ulcer, ruptured pyosalpinx, ruptured tubal pregnancy, torsion of pedicle of ovarian cyst, tabetic crises, thrombosis or embolus of the mesenteric vessels, gall-stone, renal and intestinal colic. The symptoms common to all are pain, shock and vomiting; all dependent on the same cause, namely, shock to the solar plexus. Since this group of symptoms appear in practically all acute abdominal crises they are of little value for differential diagnosis in the very early stage. "This initial stage of shock and accompanying symptoms, often transient, is usually followed by a period of reaction; a dangerous calm before a renewal of the storm—indeed, so dangerous that when prolonged by the indiscriminate administration of morphine it becomes a very pitfall in the way of correct diagnosis."

Approaching the subject in general, and from an angle somewhat different than the usual, one might classify the conditions from which intestinal obstruction must be differentiated and place them into groups, representing: I, Colics; II, Perforations; III, Inflammations; IV, Obstructions.

I. The colics are characterized by: (1) sudden onset of pain. (2) sudden cessation of pain, (3) tendency of the pain to recur. The pain in this group is usually referred to certain characteristic regions. In biliary colic it is felt in the epigastrium, radiating backwards to the angle of the right scapula and occasionally to the tip of the right shoulder. In renal colic the pain is felt, first in the loin, then shoots down to the groin, inner aspect of the thigh and testicle. Of marked diagnostic value in connection with the pain is increased frequency of micturition and blood in the urine. In intestinal colic pain is felt more or less all over the abdomen. Lead colic differs from other intestinal colics in that the pulse during the pain is retarded and the blue lines in the gums are present.

Tenderness of the abdomen is often present but in some cases, particularly intestinal colic, the pain is relieved by pressure. Muscular rigidity may occur in the colics but seldom is of the unyielding character found in the true involuntary rigidity. The patient is more restless than in other acute abdominal crises.

II. Perforations are characterized by: (1) sudden onset of pain, usually excruciating, (2) severity of the initial shock, (3) marked involuntary rigidity

from the very first, (4) there may be signs of free gas in the abdomen.

III. Inflammation.

1. In this group the onset is less sudden than in the conditions already considered, and general symptoms of malaise may precede the crises by a few days. The pain never reaches its greatest intensity in the first few moments.

2. There may be a rise of temperature in the early stage, wherein this group differs from the others mentioned. The presence or absence of rise of temperature should not, however, influence one too much in drawing conclusions and should certainly never be waited for to complete the diagnosis.

3. There is often fairly early local tenderness (sometimes first detected in the rectum as in salpingitis and pelvic appendicitis).

4. Muscular rigidity of the involuntary type, absent at first, appears when the parietal peritoneum becomes affected.

5. Swelling may later appear in the region of the appendix, gall-bladder, Fallopian tubes, etc. These signs should never be waited for in suspected intestinal obstructions.

IV. Obstructions are characterized chiefly by: (1) the persistence of vomiting, (2) the cessation of the passage of flatus, (3) progressive abdominal distention. Involuntary muscular rigidity is absent and the pain and tenderness are usually distributed more or less over the entire abdomen. As the condition progresses there is extreme distention, fecal vomiting, restlessness, pinched expression, rapid and thready pulse with profound collapse. When this stage has been reached it can be mistaken for only one other condition and that the usual termination of obstruction—general peritonitis.

If the case before us can be placed in one of the above named groups, the problem of diagnosis is at once simplified. When, however, the symptoms are indefinite or overlap as in obstruction, or perforation developing into peritonitis, the clinical differentiation is more difficult and can be arrived at only by carefully excluding all other conditions for which it might be mistaken.

Comparing the outstanding symptoms of the pathologic conditions which most commonly simulate acute intestinal obstruction we find as follows:

In *peritonitis* there is usually a history of some acute abdominal affection. In the early stage the pain is more marked and more continuous. The

distention is more general. The abdomen is immobile, noiseless and more tense. Visible peristalsis is absent, vomiting is less persistent. There is usually a rise in temperature and the increase in pulse rate a little more gradual.

Acute pancreatitis usually occurs in obese patients having a history of previous gall-bladder trouble. Pain is in the epigastric region and is very severe. Sudden profound collapse with early pinched expression and cyanosis are somewhat characteristic, but a definite diagnosis before operation is difficult.

Acute appendicitis may closely resemble obstruction in the earliest stage but usually within the safety period there is a rise of temperature, leucocytosis, localized pain and rigidity. Vomiting is not so constant. Where there is early rupture and consequent spreading peritonitis with toxemia a differential diagnosis may be difficult.

Acute perforation of gastric or duodenal ulcer. History of previous digestive trouble. The initial pain is more sudden, severe, prostrating, and constant. Shock, evidenced by pallor, cold sweat and collapse, is more marked. Pain, dullness, and spasm is usually more marked on the right side. The patient refuses to be moved. This latter with the tense board-like abdomen is characteristic.

Biliary and renal colic, except in the very early stage, offer no particular signs or symptoms which would make a differential diagnosis difficult. The spasm and characteristic pains referred to definite regions help to confirm the diagnosis.

Ruptured tubal pregnancy. The menstrual history with that of sharp, sudden, stabbing pain in the lower abdomen, together with faintness and pallor, should make the diagnosis comparatively easy; vaginal examination should never be neglected.

Tabetic crisis is often very difficult to differentiate from obstruction, because a paralytic ileus may exist as a result of the tabes. The Argyll-Robertson pupil, Rhomberg sign and the absence of kneejerk and other reflexes should put one on his guard.

Torsion of pedicle of ovarian cyst. With a history of tumor, or if pelvic examination reveals a mass in the pelvis or lower abdomen, the diagnosis is less difficult. Without the evidence of tumor and the presence of vomiting, distention and constipation—the latter often due to pain and spasm—a definite diagnosis from obstruction may be impossible before operation.

Ruptured pyosalpinx presents few symptoms common to intestinal obstruction except the first sudden pain and a gradually developing peritonitis.

Thrombosis or embolus of mesenteric vessels usually results in gangrene of a segment of the bowel with consequent cessation of passage of its contents through the part affected. The symptoms, therefore, are those of acute ileus and the demand for immediate surgical interference is the same as in acute obstruction from other causes.

Notwithstanding the improvement in surgical technic, the death rate from acute intestinal obstruction, even with operation, is still frightfully high. No surgeon denies the advisability of operating at the earliest possible moment. Yet the records of every hospital are replete with tragic stories, something as follows:

Patient admitted 6 P. M., history of pains in the abdomen, and nausea during the day. Pain, now, quite severe at times. Orders by doctor over telephone, morphine gr. $\frac{1}{4}$ per hypo. 8 P. M., patient more comfortable; vomited mucus and bile. The nurse's record the following morning: Patient comfortable the first part of night. Restless after 2 A. M. Slept only in naps. Vomited at 4, again at 5:30; light brownish color. Patient complains of some pain and tightness across abdomen. At 9 A. M. the doctor finds patient fairly comfortable *just now*. Some general distention, slight tenderness over abdomen, not localized; temperature 93.6, pulse 92. No bowel movement or flatus; face has tired expression, lips slightly dry, tongue moist. Laboratory report: leucocytes, 8,000; hemoglobin, 70 per cent. Differential, negative. Urine, highly colored. Sugar, negative; albumin, trace. Slight trace of indican. Microscopic, negative; diagnosis (?). Possible intestinal obstruction. Doctors orders: pituitrin, followed by enema; warm applications to abdomen; gastric lavage if vomiting continues.

Nurse reports by telephone at 4 P. M., fair results from enema with some flatus (when pinned down she admits that the fair bowel movement consists of highly colored water). Patient relieved after enema, but rather restless for last two hours with colicky pains, sometimes quite severe. Vomited at 11 and 3, stomach washed out; large quantities of brownish fluid with strong odor. Relieved for short time. Patient does not look so well, slightly delirious.

At 5:30 P. M. the doctor finds a little more distention, diffuse, but more marked in region of stomach, suggesting acute dilatation. Face rather pale with worn-out expression; lips more dry and a suggestion of dryness of tongue. Leucocytes, 8,500. Urine, scant; albumin and indican, positive. Temperature, 98; pulse, 100. Diagnosis still in doubt, but condition more indicative of obstruction. The doctor imparts his suspicion to the relatives and hints at surgical interference. They in turn implore him to first try everything else possible and at least wait till morning. Here we are weighed in the balance and too often found wanting; we yield, and in a last effort a purgative is ordered. At 2 A. M. the nurse reports that the patient is suffering from severe griping pains, distention more marked, and vomitus

dark brown, with foul odor; active delirium. The doctor hurries to the bedside, only to find the report of the nurse confirmed; by this time there is almost constant gulping of dark brown fluid with fecal odor, extreme distention, parched tongue, pinched expression, rapid and thready pulse, sub-normal temperature, cold sweat and extreme restlessness. The abdomen is immediately opened, only to find evidence of diffuse peritonitis, which the experienced surgeon at once recognizes as the beginning of the end.

A truly awful picture, and a terrible indictment against the profession, one to which most of us must plead guilty. We waited too long. We wanted to be sure, and while thus temporizing, the golden opportunity slipped away. Statistics complete the story.

We believe with Deaver, "that the reduction of the period between onset and operation is the prime factor. It cannot be too often repeated that during this period the essential point is *diagnosis* and not treatment. If treatment there must be at this time (and we are not blind to the fact that the physician feels the strong pressure of the patient and the family to be doing something), the physician should be sufficiently cognizant of the real issue and sufficiently resourceful not to be deluded or

forced into doing that which will endanger the certainty of the diagnosis or unfavorably influence the course of the disease.

"The danger of giving morphia before arriving at a diagnosis is well understood and it is only the densely ignorant and the incorrigible who persist in this misuse of narcotics. The purge belongs in the same category since it is even more deathly than the opiate."

The problem of acute intestinal obstruction can only be solved by early diagnosis and prompt surgical interference. It is vastly more important that we recognize an acute surgical condition in the abdomen than to wait for evidence upon which to base a definite diagnosis of intestinal obstruction.

We do not know from whence ideas come, but the importance of the idea in medical research cannot be overestimated. From the nature of things, ideas do not come from prosperity, affluence and contentment, but rather from the blackness of despair, not in the bright lights of day nor the footlights glare, but rather in the quiet undisturbed hours of midnight, or early morning, when one can be alone to think. These are the grandest hours of all, when the imagination is allowed to run riot on the problem that blocks the progress of research, when the hewn stones of scientific fact are turned over and over, and fitted in so that the mosaic figure of truth, designed by mother nature long ago, be formed from the chaos.

In the medical literature of today, we have text books, scientific treatises, journals and magazines. One wonders if there is an end of knowledge. I fancy the pages that are covered with cancer literature, if spread out, would cover the state of Illinois. Yet, its solution is not at hand. I sometimes wonder if we are helped by too full a knowledge of medical literature. I must frankly confess that had I read all that was written on diabetes and known all of the conflicting views and theories I probably would never have tackled the problem.

The young man who devotes himself to medical research must familiarize himself with the first paragraph of Osler's "Alabama Student." It begins as follows:

"Chief among the hard sayings of the Gospel is the declaration, 'He that loveth father or mother or son or daughter more than Me is not worthy of Me.' Yet, the spirit that made possible its acceptance and which is

responsible for Christianity as it is—or rather, perhaps, as it was—is the same which in all ages has compelled men to follow ideals, even at the sacrifice of the near and dear ones at home."

The man who wishes to make a success in research work must be prepared to work. He must sever his connections with labor unions that restrict the hours of his labor. He must be prepared to live, move, and have his being in the laboratory, eating and sleeping beside his work, if need be. Matrimony and research have seldom gone together. Very many brilliant young men have been overwhelmed by domestic responsibilities and have been lost to research. Here again it is well to quote Osler, "Put your affections in cold storage. * * *"

It knows no protective tariff, no embargo, no boundary line, to prevent its free dissemination for the good of all. At present it is the common language and common spirit among the nations. May I make bold to hope that American and Canadian science, depending as they do upon the efforts of individual minds, may harmoniously progress hand in hand, until that day is reached when they shall have contributed the maximum of good to the greatest number, and have brought the people at large to realize that science is the search for truth, that a true knowledge of God's creation dispels superstition, fear and disease, brings happiness, peace and prosperity, and leads to that humility with which the informed intelligence recognizes the omnipotence of the Creator.—*F. G. Banting address at the dedication of the Illinois Research Hospital, Chicago. The Institution Quarterly, Vol. xv, No. 1.*

MEDICAL CONDITIONS SIMULATING INTESTINAL OBSTRUCTION *

J. A. LEPAK, M.D.

St. Paul

When we advance the statement that medical conditions can simulate intestinal obstruction we immediately admit that intestinal obstruction can either be overlooked or diagnosed where it is not found. This is proven frequently enough when one sees occasionally a patient operated for obstruction where the surgeon does not find any, and again another patient treated medically where a bowel obstruction is discovered only at the post-mortem table. Naturally the question arises: Why do these errors occur? Is it always due to a lack of training, experience or poor medical or surgical judgment? No, it cannot be, because some of the most eminent medical and surgical authorities have made these mistakes. So it is. Why then is it so? The answer is simple. Intestinal obstruction is not always easy to diagnose.

In general these errors in diagnosis may be attributed to, first, the absence or variation, in some cases, of such symptoms as pain, shock, collapse, vomiting, constipation, distention, tenderness, visible peristalsis or tumor, known as the classical symptoms of intestinal obstruction; second, to the simulation of like symptoms by strictly medical conditions. It is natural then for the sake of clearness to divide the discussion into three groups.

The first deals with definitely surgical conditions; the second considers conditions medical at first, which, however, eventually become surgical; the third group embraces strictly medical conditions simulating intestinal obstruction.

Since the first group of conditions has been covered comprehensively in the preceding papers it shall be dismissed here with mere mention.

The next group comprises both surgical and medical conditions. The absence or variations of symptoms is so marked at first that a diagnosis of an underlying surgical condition is impossible; hence the patient, while under constant observation, is temporarily treated medically. This variation of symptoms is usually dependent on the height and completeness of obstruction. High bowel obstruction most commonly gives extreme pain, shock and

vomiting; constipation and distention may appear later and visible peristalsis is usually absent. Low obstruction again generally produces slowly distention and constipation, pain is less severe and the shock may be very slight, while vomiting is either absent or occurs very late in the disease. The next factor adding to the confusion or variation of symptoms is completeness or incompleteness of bowel obstruction. In intussusception and mesenteric thrombosis or embolism incomplete obstruction may obtain and symptoms like constipation and distention may be absent or replaced by tenesmus and bloody stools. Thus simulation by Hanoch's purpura, cirrhosis of the liver, enteritis and colitis is possible. It has been demonstrated, however, that most of these cases suffer from either partial or chronic intestinal obstruction. Of course, these cases are surgical, but the operation is delayed because in the beginning a definite diagnosis of the underlying surgical condition cannot be established. To this group one may add also a few medical conditions which, failing to respond to medical treatment, demand surgical intervention. Such conditions are produced either by mechanical agents in the bowel or by functional paralysis of the intestine. The most frequent mechanical obstructions are due to fecal impaction, parasitic infestation and foreign bodies. Functional paralysis of the bowel may follow a severe injury to the testicle, ovary or hernial sac. It also may occur after a hemorrhoidal operation, abdominal paracentesis for large quantities of fluid, after passage of a renal and biliary calculus, and even rarely following operations not on abdominal viscera.

To the third group simulating intestinal obstruction belong strictly medical conditions demanding only medical treatment. The onset practically of any violently acute contagious or infectious disease must be considered. The onset occasionally of such diseases as Hanoch's purpura, enteritis, colitis, typhoid fever, and cholera may simulate intestinal obstruction. A severe pleurisy or pneumonia may produce, by its toxic products acting on the nervous mechanism of the bowel, a paralytic ileus. This usually is temporary and can nearly always be relieved by medical measures. Mannaberg and Osler, however, both record cases where an operation was necessary to relieve the paralytic obstruction. Uremia and poisoning from arsenic and lead may produce symptoms simulating bowel obstruction. One,

*Presented in symposium on Intestinal Obstruction at St. Paul Clinic Week, January, 1924.

of course, is endogenous, the other two exogenous in origin. A urinalysis will usually suffice to suggest further study of the case. A renal function and blood chemistry test with a blood pressure study will be confirmatory of kidney insufficiency. The occupation, lead line, and stippling of red blood cells are important factors in making a diagnosis of lead poisoning. Injuries or irritations to the nervous system, whether organic or functional, can also imitate symptoms and signs of ileus. One must, therefore, rule out any local injury to the peritoneum or omentum. Distant disease, again, e. g., in the thorax, may so irritate the sensory nerve segment that seemingly alarming symptoms are present mostly in the abdomen. The most frequent confusing of the spinal diseases is tabes dorsalis. An Argyll-Robinson pupil with absence of knee jerks usually makes one consider syphilis. Sometimes so-called functional neurosis, such as hysteria, adds to our confusion. A careful familial and personal history together with a superabundant and frequently dissociated number of symptoms places one at least on guard for possible neurosis.

CONCLUSIONS

1. Intestinal obstruction is not always easy to diagnose.

2. The examiner ought to group the possibilities into one of the following groups:

(a) Surgical and operate at once.

(b) Medical at first, but later surgical due either to an insufficient or seemingly incompatible number of findings to form in the beginning a surgical opinion, or to a definitely medical condition which, failing to respond to medical measures, must receive surgical intervention. The medical treatment in this group ought not to continue longer than twenty-four hours, because the surgical mortality bears a direct ratio to the delay of the operation. It is in this group that all medical and surgical authors agree with the statement, "when in doubt operate."

(c) The third group is strictly medical and yet when authors like Mannaberg and Osler each report seeing pneumonia, by its toxicity, producing a paralytic ileus which demanded surgical intervention, we can then appreciate properly how medical conditions can simulate intestinal obstruction.

THE CLASSIFICATION AND TREATMENT OF HEMORRHOIDS*

W. A. FANSLER, A.M., M.D.

Instructor in Surgery, University of Minnesota
Minneapolis

In the brief time assigned to this paper it is impossible to discuss all of the details and minor considerations incident to the many methods devised for the treatment of hemorrhoids. I merely hope to outline enough of the more important points to arouse some thought in this direction. The chief demand of the patient is that he be given a permanent cure and that he suffer as little pain as possible. In fact, pain is usually one of the chief considerations to him. It is quite possible to give him a permanent cure with practically no pain if we keep certain anatomical relations in mind and act accordingly. It will be recalled that almost all of the nerves of sensation of this region lie within the anal canal and that the rectum itself is almost insensible. It is this one point which enables us to care for these cases practically without pain. A minimum of trauma to the anal canal means a minimum of pain for the patient.

The most simple classification of hemorrhoids which I know is to divide them into two distinct varieties. First, the internal, which lie above the junction of the anal canal and the rectum and are covered by the velvety appearing, mucous-secreting, columnar type of epithelium. Second, the external variety which lie at the outer orifice of the anal canal, are covered by true skin and appear as a bluish swelling when the patient strains and the varicosities composing it are engorged with blood. At least half of the patients presenting themselves do not show either of these distinct types of lesion. More often than not a varicosity forming an internal hemorrhoid will extend downward into the anal canal thus forming an interno-anal hemorrhoid, or the varicosity of an external hemorrhoid may extend upward into the anal canal, thus forming an externo-anal hemorrhoid. Not infrequently the varicosity will extend from within the rectum downward, completely through the anal canal, joining with an external hemorrhoid below to form an interno-ano-external variety. This may seem to be an unnecessarily detailed description of a condition

*Presented before the Noonday meeting of the Hennepin County Medical Society, Wednesday, April 16, 1924.

so common as piles, but it is the recognition of these distinctions that enables us to cure them with little pain. Only too many cases are operated on the catch-as-catch-can principle, anything that is protruding being seized and burned or cut off without regard to its relation to the sensory nerve supply.

Whatever method may be decided upon it must be remembered that the anal and external varicosities must be considered as a separate condition from those inside the rectum. I believe that the two best methods of dealing with the anal and external varicosities are as follows: First, the method of excision, in which case the redundant portion of the overlying skin and mucous membrane is removed by sharp dissection and through this opening the varicosities carefully dissected out. The second method is to make a buttonhole incision at the base of the pile and inserting the blades of a pair of scissors through this opening macerate the varicosity, thoroughly destroying the vessels. This is done entirely subcutaneously and with care the skin is not cut except at the point of entrance. This leaves the anal canal intact and there being no raw surfaces the bowel movements are painless. Theoretically this method may not be quite as accurate as the first, but it is less painful and with experience the results are good. In connection with this type of hemorrhoid it is well to add that there are no vessels in the anal canal that it is necessary to ligate. This is a most important consideration for one ligation tied on anal tissue will cause the patient severe and prolonged pain. Only under most unusual circumstances should any ligatures or stitches be taken in this region and cauterization should never be done. If either ligatures or stitches are used pain is certain to result and should be expected.

The anal and external varicosities having been dealt with, the next consideration is the treatment of the internal hemorrhoids or true rectal varicosities which remain. Personally, I usually eliminate these either by the injection of a 5 per cent solution of quinine urea hydrochloride or by ligation; but I also wish to mention other methods and to point out their advantages or disadvantages. In many cases with the internal hemorrhoids there is a greater or less prolapse of the rectal mucous membrane and in choosing a method of cure this must be taken into consideration.

The clamp and cautery method is one of much repute in the Northwest. I can only attribute this

to the fact that until very recently it was the usual operation done at the Mayo Clinic. Personally, I have never seen much excuse for this method. If the cauterization is confined to the rectum alone it is not painful, but usually some anal tissue is also included in the burn and then the patient's agony begins. As a matter of fact many who now profess to favor the clamp and cautery do not really do the clamp and cautery operation. They first dissect up the hemorrhoid and then applying the clamp around the shred of tissue left at its base announce that they have done a clamp and cautery operation. One reason advanced in favor of this method is that it is extremely simple and anyone can do it. If it is simply a question of seizing any protruding or bulging tissue with the pile clamp and then burning it off it is "simple." After the pain has subsided the resulting scar may produce relief if it does not produce a stricture. However, knowing the pain caused by a burn and the cicatrix and contractions resulting from it, I cannot feel that it is a very safe procedure to turn anyone but an expert loose in the rectum, with a pile clamp and a hot soldering iron. I have seen only one stricture following a ligation operation and I have seen many following clamp and cautery. Aside from the pain and granting that in the hands of an expert there is no danger of stricture, there is still another more important reason why to me this method is not good. I do not believe that it is humanly possible to do an accurate removal of all the varicose veins with instruments as crude and clumsy as the clamp and cautery. Some varicosities are almost certain to be left and some healthy tissue sacrificed. Examinations of these cases after operation will prove this point in many instances.

What is really the result when the clamp and cautery is done and why is the percentage of apparent cures fairly high? In the first place several lines of cauterization are made along the long axis of the bowel. The scar produced by this binds the mucous membrane to the muscular coat of the bowel as in the case of linear cauterization for prolapse. This, of course, prevents protrusion and relieves the patient of this symptom. However, it does not prove that no piles are present; it only proves that they no longer protrude. If the rectum is inspected through a speculum large varicosities will often be seen clinging to one or both sides of these lines of scar, tethered in place like a toy balloon on the end of a stick. The scar prevents

their protrusion but they are there and likely to cause trouble later.

As has been previously stated, prolapse of the mucous membrane is present with many cases of hemorrhoids. As a matter of fact, many cases are treated as hemorrhoids, where the chief trouble present is really a prolapsus. In these cases a few varicosities appear to protrude through the anus and so hemorrhoids are diagnosed, but if more careful examination is made it will be seen that these varicosities are small. The major part of the protrusion is really a prolapsus of the mucous membrane which, in sliding down, has carried a few hemorrhoidal vessels with it. I would say off hand that fifty per cent of the persons complaining of hemorrhoids have this condition. Clamp and cautery does relieve this type of prolapse. If these cases are examined after operation all of the piles appear to have been removed, the reason being that there were really no piles present in the first place. If the cases which actually have large internal hemorrhoids were considered I believe practically all of them would show a considerable amount of hemorrhoidal tissue left after the clamp and cautery operation. Either this or a stricture would be present.

Another method of dealing with internal hemorrhoids is advanced by Dr. Murray of Duluth, who uses it on both internal and external type. This, as was previously described, is to make a button-hole incision at the base of the pile, then with scissors to destroy subcutaneously the hemorrhoidal vessels. This is a useful method, but requires more experience to do well than open dissection with ligation. The inexperienced are likely not to destroy the vessels thoroughly enough. It is less painful than complete excision. In my opinion, it should not be used in cases associated with prolapse of the mucous membrane, which, as was previously stated, is quite common.

Method of injection.—In this case I use the injection of a 5 per cent quinine urea hydrochloride solution, based on the original work of Dr. Terrill of Richmond, Virginia. These injections are made at weekly intervals, using from 0.5 to 2 c.c. of solution. More than one injection to a hemorrhoid may be necessary. These injections are not very painful and have the advantage that the patient can work every day. The time of cure is usually from six to eight weeks, but this period can be shortened to two or three weeks if the patient can be quiet.

This method may be employed even where there is some prolapse of the mucous membrane, for if a few injections of the fluid are made between the mucous and muscular coats as well as into the hemorrhoids, the reaction produced will cause scar tissue to form which binds the mucous and muscular coats together, thus curing the prolapse. I have previously described this procedure in a paper presented before the Southern Minnesota Medical Society. The danger of embolus, liver abscess, etc., is frequently mentioned as an argument against the injection method. I can only say that it never as yet has occurred in my experience, nor do I believe there is much danger if ordinary antiseptic precautions are observed. That they may occur if one is careless of his technique is quite possible. We all know of occasional deaths and other serious complications following operations for hemorrhoids, whether done by clamp and cautery, ligation or other methods. It may be possible that eventually some misfortune may attend a case where I have employed the injection method. Nevertheless I feel that the method is at least as safe as any other. Electrolysis may be used in the same cases where injection can be done and the same principles apply.

Ligation.—Where operative procedure is necessary or decided upon I feel that this is the method of choice. My preference for this is that all pathological tissues may be accurately dissected out and removed as cannot be done with the clamp and cautery. This applies whether simply hemorrhoids or hemorrhoids and prolapsus exist. The external, anal and internal are all done with one dissection and it is relatively painless. There are two variations of the method which I think best. The first is to bring the internal hemorrhoid into view; then with a curved needle take a stitch at its upper pole. Tying this, the vessel supplying the hemorrhoid is cut off, and the procedure rendered almost bloodless. The ends of the ligature are left hanging and the lowermost part of the hemorrhoid seized and dissected upwards almost to the ligature and a tie then made around the stump. This method has the advantage of being almost bloodless, but the disadvantage of stitching through the rectum. This probably increases the danger of infection and often delays the separation of the ligature. The second method is to start the dissection at the lowermost part of the varicosity, carry it well up into the

rectum and then ligate. This method requires no stitch, but it is more bloody and unless the ligature is tied very close to the mucosa it may leave a little polyp-like tab of mucous membrane when the ligature separates. I usually leave the ligatures long, for by so doing they act to a certain extent as a wick, and, what is more important, it can be told when they have separated. If they are unusually slow, gentle traction each day will hasten their separation.

This paper is entirely a personal one and the synopsis of the various methods represents only my own convictions. I hope it will arouse interest in some of those present to continue to investigate problems in this connection. While we may not always agree, it is only by exchange of ideas that we progress.

RESTRICTIONS IN LICENSURE EXAMINATIONS TO THINGS THAT ARE SIGNIFICANT

Attention is again directed to the subject discussed by Dean Edsall in an article recently published in the *Bulletin*.

This article emphasizes particularly that state boards like medical schools are more concerned with the increasing of requirements, mainly as to the simple acquisition of facts rather than an intelligent contemplation of these facts, or the comprehension of the competent use of them.

There is an increasing tendency because of tradition and custom, both in teaching and licensure examination, to retain certain knowledge and facts that are obsolete and have long ceased to be of value.

There is no question that the medical curriculum, as well as qualifying examinations, have become extremely rigid in this country. It has been well said that there is less intellectual freedom in the medical course than in any other form of professional education. Individuality is submerged and there is little opportunity for developing individual responsibility.

It is time also that the quality of knowledge should take precedence over quantity, and this applies particularly to licensure examinations. This appeal from Dr. Edsall to examine only in the significant and important things is therefore very timely.

The state boards responded promptly to the general request that examination in materia medica, pharmacology and therapeutics be limited to the more important drugs. Why cannot this same principle be applied to the other subjects?

It is earnestly hoped that the Federation will offer its fullest co-operation so that this most desirable change in examination methods can be brought about.—*Federation Bulletin, Vol. X, No. 5.*

ETHYLENE ANESTHESIA: REPORT ON USE AT ANCKER HOSPITAL

J. RICHARDS AURELIUS, M.D.

St. Paul

Inspired by the results of the experimental and clinical work of A. B. Luckhardt and J. B. Carter of Chicago, and of W. E. Brown, of Toronto, pioneers in the recent development of ethylene anesthesia, we decided recently to give ethylene anesthesia a thorough trial at this hospital to determine whether or not it had a practical application in a hospital of this type, considered from both a clinical and financial standpoint. Since our first ethylene anesthetic we have used it to the exclusion of all other general anesthesia, except when several operations were scheduled simultaneously so that the ethylene apparatus was not available for all. We have made the following observations on 300 cases of ethylene anesthesia through a wide range in the field of minor and major surgery.

We desire here to express our indebtedness to Miss T. Zita Costello, R.N., anesthetist, and Dr. Carl Stomberg for their aid in the preparation of this report.

An analysis shows that of the three hundred cases, 194 were major surgical procedures, which included 12 cholecystectomies, 20 salpingectomies, 43 appendectomies (of which 27 included general peritonitis), 22 herniotomies, 8 hysterectomies, 3 thyroidectomies, 5 ectopic pregnancies, 3 thoracoplasties and 2 gastro-enterostomies. The minor surgical procedures were chiefly perineal repairs, curettements, abscesses, reduction of fractures, and the like.

The age limits varied from an infant of two months, with a sub-periosteal abscess (mastoid), to an adult male of seventy-seven years, who was anesthetized for implantation of radium needles. Fourteen cases were sixty years or over and thirteen cases were six years or younger. For both age extremes, ethylene anesthesia had no bad effects, but rather seemed an ideal anesthetic because of the ease and rapidity of induction, the quiet, undisturbed respiration, the regularity of the pulse during the anesthesia and the absence of any untoward post-operative symptoms such as shock, pulmonary involvement or severe vomiting. We have experienced nothing that would indicate that ethylene

anesthesia is anything but the safest and most desirable anesthesia at present available for the extreme age limits.

For the 300 cases, 208 hours of ethylene-oxygen gas were used, giving an average of forty-three minutes per case, with seven cases consuming more than two hours. In 40 of these cases, ether was used at some stage of the operation, sometimes to aid relaxation or during induction in cases where the patient was unduly excitable or unyielding.

The induction period for ethylene has averaged four and one-half minutes. A few cases required up to eight and ten minutes for induction, but when a longer period than this was consumed ether vapor was found to be necessary, as in two cases of general peritonitis. In practically all cases the induction has been quiet and free from struggling and talking. In some alcoholics and in some cases of severe peritoneal involvement, the induction was modified very much, making it necessary to add ether vapor. However, in many such cases, the patient was very slow to yield even with ether as an adjunct and this was generally true of all cases that did not yield promptly to ethylene.

We have found in the great majority of cases the relaxation has been very satisfactory for practically all major procedures. The relaxation is definitely more complete than with nitrous oxide, and less than with ether in some cases. In 40 of our cases we have used ether in some part of the operation and this has been necessary either during the induction or during severe peritoneal or mesentery manipulation. The ether used has varied from a few minutes up to fifteen. These cases were often relaxed only with great difficulty and sometimes unsatisfactorily, even when ether was added. We have been led to believe that the commercial ethylene varies or that certain impurities may be present in different cylinders because twice, upon using new tanks of ethylene, the relaxation was very poor in all cases using that gas, and upon replacing the cylinders for others no further trouble was experienced.

The recovery from the anesthetic has been uniformly prompt in all cases, even when ether has been used. The patient is oriented in one to two minutes and the length of the anesthesia does not seem to affect this prompt recovery. Just before awakening there is a vomiting reflex present which not infrequently causes the patient to regurgitate usually a mucous material. Sometimes there is

definite vomiting while the patient is still on the operating table, but usually this does not occur after the patient has awakened from the anesthetic.

During the anesthesia the patient's skin remains remarkably dry, noticeable perspiration having been present in less than ten cases, and usually this has appeared during a strenuous induction period, as occurs in most alcoholics. The color remains normal, and in no case has there been cyanosis, regardless of how hard the anesthesia has been pushed, providing the minimum oxygen percentage necessary for respiration has been given. The sleep is very quiet, the respirations uniformly deep and regular, simulating exactly a normal sleep. Record of the pulse and respirations before, during, and after the operation have been kept as a part of the anesthesia record. The pulse and respirations before operation are those charted on the ward just before the patient is sent to the operating room. During the operation they are recorded about every five minutes, and following the operation they are again recorded as soon as the patient has awakened, before he leaves the operating room. In analyzing these records, we find the respiration rate was increased in 132 cases, an average of 3.8 respirations per minute, in all cases, and for those that had ethylene only (no ether), a rise of 2.8 respirations per minute. The respirations were decreased in 47 cases, an average of 2.8 respirations per minute or 2.5 for those patients who had no ether. The remaining 121 cases showed no respiratory change. The pulse in 150 cases was increased an average of 7.8 beats per minute or 5.7 beats in those cases where ethylene alone (no ether) was used. It was decreased 5.3 beats per minute in 97 cases, and for those cases that had ethylene only, a decrease of 5 beats per minute was shown, also a negligible difference. The remaining 53 cases showed no pulse changes. Therefore, we find that in ethylene anesthesia, including cases where a small amount of ether has been used, that there is a slight decrease or no change in the respiratory rate in 75 per cent of the cases, and in the other 25 per cent, the increase is only three to four respirations per minute; that the pulse remains the same or is decreased in 50 per cent of the cases and that in the other 50 per cent there is an increase of seven to eight beats per minute. When we exclude the patients who have had ether we find that there is practically no difference, the reason being that very little ether was used in any case.

We have been unable to take blood-pressure readings on all cases but those that have been taken have shown no appreciable change during or after the anesthetic. On a number of patients we have taken the clotting time before and during the anesthesia and here also we have not been able to demonstrate any change.

Following an operation in a patient who has not had premedication of morphine, we find that the patient complains of pain very soon and that morphine is usually necessary within fifteen to thirty minutes after return from the operating room. Patients who have had morphine previous to the operation do not complain of pain nearly as soon and often can go several hours before medication is necessary, but other conditions being equal, it is necessary to give medication for relief of pain considerably earlier in ethylene cases than in ether cases. Morphine premedication does not seem to have any effect on the course or ease of administration of the ethylene anesthesia.

The results from ethylene anesthesia from the standpoint of post-operative nausea and vomiting have, indeed, been very gratifying and we are likely to speak so favorably as to seem overenthusiastic. However, in comparing the period of our use of ethylene with a like period just prior to its use here, when ether and nitrous oxide were our anesthetics, we note a very appreciable lack of post-operative nausea and vomiting and an unusually uneventful convalescence of cases on all surgical services. Examination of records shows that there has been some vomiting after return from the operating room in 61 cases, sometimes only once and often very slight, and in only a few cases prolonged and severe. Twelve of these cases had ether during some part of the anesthetic. These cases include 6 cholecystectomies with appendectomies, 8 appendectomies, 5 salpingectomies, 3 ectopic pregnancies, 2 thyroidectomies, 3 hysterectomies, 3 curettages, 3 herniotomies, 3 pelvic abscesses with general peritonitis, 1 thoracoplasty, 1 nephrectomy and 1 orchietomy. The severest and most prolonged vomiting has been noted in cases of severe shock, as in acute appendicitis with general peritonitis and as in one case of ectopic pregnancy, where the bleeding had been excessive and the patient was in considerable shock. In the gallbladder cases, the vomiting was most frequently present (six cases out of twelve), but not prolonged or excessive. Several patients had a definite psychic element

present that unquestionably modified the post-operative course. These 61 cases do not include the cases that vomited while still on the operating table before awakening fully from the anesthetic. This has happened more frequently than the vomiting after leaving the operating room. This vomiting is probably due to the return of reflexes as the patient is awakening, as most commonly it consists of only a few contractions or attempts at vomiting, often producing only a bile-stained mucoid emesis. Very occasionally, this vomiting may be considerable in amount.

It is interesting to note that there has been very definite indication of inequality of the commercial ethylene, as stated before. We had two tanks at some considerable interval apart that seemed to be different from the usual ethylene in that the incidence of vomiting would be present successively and persistently until the cylinder being used was exchanged for a new one, when its occurrence would drop immediately to normal frequency. We have been unable to attribute the coincident difficulty of fully anesthetizing patients and the increased vomiting to anything but impurities in the ethylene. In the 300 cases there were less than 10 cases of severe vomiting, regardless of the condition of the patient, and the stomach lavage has been necessary but 4 or 5 times. Including all cases, vomiting either mild or severe has been present in less than 25 per cent of the cases.

Gas pains have been the source of very little complaint; certainly, very definitely less than for ether anesthetics and when present have usually been in cases of severe peritoneal irritation.

Food can be more freely given than after ether anesthesia. Liquids have been taken very freely in most cases on the day of operation and often broths or even milk drinks have been tolerated, depending, of course, upon the length of the anesthesia and the nature of the surgical procedure. On the first and second post-operative day soft diet has been well taken where the operative condition has not contraindicated.

The general convalescence has unquestionably been far more uneventful and definitely more rapid in the ethylene cases and the general condition of the patient, especially the first post-operative days, is surely better than with other general anesthetics. Undoubtedly, this is a factor in speeding up the convalescence and a patient's stay in the hospital.

Of the cases of special interest, we wish to men-

tion that of a patient operated for acute appendicitis, who had a history of angina pectoris. This patient was anesthetized with ethylene at 9:45 A. M. and in twenty minutes had an attack in which the pulse became slower and very weak, the extremities became cold, the body was cold, and covered with excessive perspiration, and the respiration rate decreased. The operation was stopped and the patient given oxygen immediately, coming out of the anesthesia very promptly, but apparently in considerable pain. In about five minutes the attack had subsided and the patient was re-anesthetized and the operation was finished uneventfully. It is a question, of course, how well the patient would have fared with an anesthesia less easily controlled than ethylene, and whether the operation could also have been finished without further disturbance.

In the case of a boy, aged 7, we had the coincidence of an acute appendicitis (ruptured) and a lobar pneumonia. The patient was very sick, but surgery was necessary, and the appendix was removed under ethylene anesthesia. The boy recovered in the usual time of a drainage case, with no further complications and the pulmonary condition apparently in no way affected by the anesthesia.

Two cases of thoracoplasty on tuberculous patients have been successfully performed under ethylene anesthesia in which the patients recovered promptly from the surgical procedure, evidently suffering very little shock and giving no evidence of irritation or disturbance to the pulmonary condition. In one case, the first stage was done before ethylene had been instituted at this hospital, so that local and nitrous oxide anesthesia was used. The anesthesia was quite unsatisfactory, the patient having considerable pain and suffering definite shock. With the second stage, in which portions of a larger number of ribs were removed and the procedure generally was more radical, we had an uneventful ethylene anesthesia, with practically no post-operative shock and a very rapid recovery.

The average cost of ethylene-oxygen anesthesia, as it is given routinely, has been about \$2.40 to \$3.00 per hour, with the ethylene alone averaging about \$2.00 to \$2.40 per hour. It is evident that ethylene costs definitely much less than nitrous oxide and about that same proportion more than ether. However, in considering the advantages of ethylene over the other general anesthetics, especially from the standpoint of the comfort and well-being of the patient, besides the saving in shorter

hospitalization, the extra cost is well compensated for.

SUMMARY

1. All ages seem to tolerate ethylene anesthesia very well, and it is, apparently, an ideal anesthetic for both the age extremes.

2. Induction has been quiet and rapid, except in some cases of alcoholics and general peritonitis.

3. The relaxation has been usually sufficient for all surgical procedures. In cases where it is not sufficient with ethylene-oxygen alone, ether vapor, which is easily administered in conjunction with the ethylene-oxygen apparatus in small amounts, gives the desired relaxation, without affecting the post-operative results of ethylene anesthesia.

4. The recovery from the anesthesia is uniformly prompt. It is not infrequently accompanied by a momentary return of the vomiting reflex.

5. Seventy-five per cent of cases show a slight decrease or no change in the respiratory rate and the other 25 per cent have a rise of 3 to 4 respirations per minute. Fifty per cent of the cases show a slight decrease or no change in the pulse rate and the other 50 per cent show only an increase of seven to eight beats per minute.

6. There has been no noticeable change in blood pressure either during or after the anesthesia; nor has the blood clotting time been changed from normal during the anesthesia.

7. Medication for relief of pain after operation is necessary sooner after ethylene cases than for ether.

8. In our series of cases, which included both minor and major surgery, the vomiting following operations has been present in about 25 per cent of cases; very rarely is it severe or prolonged, and usually occurring but one or two times. Slight vomiting is quite frequently present in the operating room, just before the patient awakens. Impurities in the commercial ethylene undoubtedly are an important causative factor for some post-operative vomiting.

9. Pulmonary conditions apparently are not affected by the ethylene anesthesia; at least it can be given with relatively very little danger.

10. The cost of ethylene-oxygen anesthesia is considerably less than for nitrous oxide, and though more costly than ether, its many advantages definitely offset this increased cost.

Ethylene Anesthesia

The gas ethylene (C_2H_4) is one of the new general anesthetics. It was introduced by Luckhardt and Carter, and was first used in the Presbyterian Hospital, Chicago. It is one of the hydrocarbon gases which is prepared by removing one molecule of water from grain alcohol. It may be looked on as an anesthetic occupying an intermediate place between nitrous oxide and ether, and has certain very distinct advantages.

Ethylene may be given through the ordinary gas inhaler. About 20 per cent of oxygen must be combined with it. It mixes satisfactorily with ether, and through the ordinary inhaler, from 1 to 25 per cent of ether vapor may be given at any time. Anesthesia may be produced by ethylene within two or three minutes, and with very little discomfort to the patient; very seldom is any excitement or sense of suffocation experienced. When ethylene is properly given very little change in the pulse or respiration is noticed. Patients perspire but little and awaken quickly after the anesthetic is withdrawn. It is borne well by the lungs and

there is little tendency toward accumulation of mucus in the respiratory tract or throat.

The relaxation produced is sufficient for all ordinary operations outside the abdomen, but in order to obtain the proper relaxation in intra-abdominal operations it is often necessary to use in conjunction with ethylene other substances which tend to increase relaxation. One-sixth of a grain of morphin administered half an hour before an operation tends to increase the efficiency of the anesthetic, and in abdominal work greater relaxation may be produced by the injection of 0.5 per cent novocain solution in the subperitoneal tissues after the incision has been made through the skin, aponeurosis and muscles. In all abdominal operations the narrow margin of anesthesia produced by ethylene may be broadened, and relaxation increased by administering also a small amount of ether (1 to 8 per cent). There is probably as much vomiting following ethylene anesthesia as following ether, but the reflexes are quickly regained after the anesthetic is discontinued, and patients are usually well able to take care of any material vomited.

In obstetrical work a combination of nitrous oxid and ethylene has proved very satisfactory. As an adjunct to local anesthesia during certain periods when it is necessary to make traction, and so forth, ethylene is also of great advantage on account of the rapidity with which anesthesia is produced and the ease with which patients awaken after it is discontinued.

Ethylene has the disadvantage of being a very inflammable gas, and cannot be safely given while a thermocautery of any sort is being used. This difficulty may be overcome by discontinuing the use of ethylene gas and supplanting ether for a few minutes before and during the time the cautery is to be used.

Ethylene given in lethal doses to animals kills by paralyzing respiration, but cardiac failure is late in developing, and after respiratory failure has occurred animals may be resuscitated by inducing artificial respiration.

Surgeons who work with ethylene as an anesthetic, especially in the abdominal cavity, should develop a technic similar to that used in operating under local anesthesia; that is, gentle manipulation with as little traction as possible on the abdominal walls or abdominal organs.

For many years ether has occupied a prominent

place among anesthetics; it is so safe and produces such excellent relaxation that it will be difficult to displace it completely with another anesthetic. Ethylene may be regarded, however, as one of the newer anesthetics, which will probably occupy an important place unless it is replaced by an agent which is less inflammable, or superior.

W. E. S.

The Arrangements for Meeting Places for Medical Societies

As previously stated in this Journal the meeting of the American Medical Association from June 9th to 14th was held on the new Municipal Pier in Chicago. It was the largest in point of attendance ever held. The various sections were all housed in subdivisions of the pier under one roof. The halls were made by building up the lateral walls from the floor to the roof and subdividing the long pier by means of some thin material similiar to compoboard. A small door was placed at the rear end of each hall for the purpose of entrance and exit of the fellows. A platform about three feet high was placed at the other end of each room and folding chairs were distributed throughout the hall.

While it was of great advantage to have all the sections meet under one roof and the space allotted for displays was ideal, there were some features about the arrangements for the meeting which were unsatisfactory and offer subject material for some observations.

The inadequacy of the halls themselves was perhaps more noticeable in the larger sections. The only provision for ventilation was through the small door in the rear of the hall. Incidentally, when this door was open or when the curtain overhanging it was pulled aside a flood of light entered the hall which interfered greatly with the demonstration of lantern slides. The acoustics were so bad that in some of the halls anyone situated toward the rear could hear only the loudest speakers. To add to the difficulty in hearing, street cars and trucks passing along outside the pier contributed sufficient noise to be most exasperating. In addition, the constant movement of the chairs about the floor incident to the coming and going or the restlessness of the fellows added to the turmoil. As a matter of fact, it was necessary for the individual, if he wished to hear the speakers, to sit so

near the front in some of the large halls that the lack of ventilation was most depressing. The absence of shaded drop-lights and speakers' stands was also noticeable.

Poor acoustics, poor ventilation and lack of facilities to show lantern slides always have a tendency to make the members become restive and at this meeting it was our observation that occasions in which those farthest from the stage were not talking with each other, moving their chairs around and adding to the inconvenience of those who were trying to listen were the exception rather than the rule.

It is an indisputable fact that the hall presenting perfect acoustics, immovable chairs, carpeted aisles, a maximum of elimination of noise and facility for the demonstration of lantern slides or motion pictures without unnecessary delays gives the speaker the best opportunity to present his subject and gives his listeners likewise an opportunity to gain the maximum benefit therefrom.

In these matters the local committee of arrangements of any medical association has an important duty to perform. Attention to the above mentioned details before the opening of the session should receive more attention than it has in the past.

Too often, men have spent a great deal of time and money in the preparation of lantern slides or motion pictures only to find on their arrival at the meeting place that no provision has been made for the exhibition of the same. While it is true that arrangements were made for the exhibition of motion pictures in a separate hall, this method of teaching and demonstrating has reached the stage where a motion picture outfit should be available before any of the sections should some contributor to the program find it desirable.

This criticism, which is intended to be entirely constructive, applies as well to the meeting places of all medical associations as to that of the national organization. In our opinion there is, however, decidedly less reason for failure to provide each section with the simple prerequisites mentioned above when considering the meeting of the American Medical Association than there is in regard to most other organizations and it is in the hope of bringing about an improvement in these important details during future meetings that this criticism is made.

OBITUARY

DR. O. M. HAUGAN

Dr. O. M. Haugan, well known physician of Fergus Falls, died at St. Luke's Hospital, Fergus Falls, May 25, 1924, as a result of cerebral hemorrhage and complications.

Dr. Haugan was born near Trondhjem, Norway, fifty-seven years ago. At the age of five he came with his parents, a brother and three sisters, to South Dakota. Here near the village of Volin, where he was raised, he was brought for burial in the family lot, where his parents and two sisters had been laid to rest before him.

After attending the country public schools, Otto Haugan went to Red Wing Seminary, where he graduated from the Collegiate Department. He also taught there during the last year of his course. He later taught in the public schools of Ottertail County, Minnesota, and in Iowa. He then entered the University of Minnesota and finished the literary course in three years, following which he returned to Ottertail County, where he served for several years as superintendent of the county schools.

Dr. Haugan received his medical training at Northwestern University. Following his graduation there in 1902 he came directly to Fergus Falls, where he practiced to the time of his death, a period of twenty-one years.

Dr. Haugan was a man of lovable disposition and was very popular in his community. While he kept abreast with medical progress by taking some post graduate work almost every year, he never lost his interest in educational activities to which his earlier life was devoted. He was a member of the school board and was much in demand as a public speaker at graduation exercises and at various meetings of young people's societies. His entire life was a reflection of early training in a Christian home and his motto in life was "Service." He died as he had lived in the midst of service to his fellow men.

THEO. S. PAULSON, M.D.

DR. BENJAMIN HARVEY OGDEN

Dr. Benjamin Harvey Ogden, St. Paul, died on June 12, at the age of sixty-four years.

Dr. Ogden was born in Northfield, Minnesota, where he received his early schooling and was graduated from Carleton College in 1881. He received his degree as Doctor of Medicine from Hahnemann Medical College of Philadelphia in 1885.

After practicing his profession in Northfield for a year, Dr. Ogden moved to St. Paul, where he was actively engaged as physician and surgeon until failing health a year ago forced him to retire. Dr. Ogden was a member of the staffs of Ancker, Miller, St. Luke's and St. Joseph's hospitals in St. Paul. He had also held the presidency of the State Homeopathic Society and was for a time connected with the College of Medicine at the University of Minnesota and held membership in both the Ramsey County and Minnesota State Medical Associations.

Dr. Ogden is survived by his wife, a daughter, Mrs. Arletta Kuby, and a son, Dr. Warner Ogden of St. Paul.

REPORTS AND ANNOUNCEMENTS OF SOCIETIES

MINNESOTA STATE MEDICAL ASSOCIATION

The annual meeting of the Minnesota State Medical Association is scheduled to meet in St. Cloud, Wednesday, Thursday and Friday, October 8, 9 and 10, 1924. Arrangements for the program are nearing completion in the hands of the Program Committee, which is made up of the chairmen of the two sections, Medicine and Surgery, Dr. E. L. Tuohy, Duluth, and Dr. A. C. Strachauer, Minneapolis, and the secretary of the State Association, Dr. Carl B. Drake, St. Paul.

Dr. C. B. Lewis, St. Cloud, who is acting as chairman of general arrangements, is completing plans for the meeting with the aid of the following local committees:

Committee on Exhibits—H. W. Goehrs, Chairman, I. E. Bowing, H. F. Clark.

Committee on General Entertainment—Wm. Friesleben, Chairman, P. E. Stangl, T. N. Fleming.

Committee on Hotel Accommodations—J. H. Beaty, Chairman, J. C. Boehm.

Committee on Entertainment of Ladies—J. P. McDowell, Chairman, C. A. Rathburn.

Committee on Lantern Slides—M. J. Kern, Chairman, C. F. Brigham.

Committee on Reception of Members—W. L. Beebe, Chairman, A. D. Whiting.

Committee on Telephone Service—F. H. Stangl, Chairman, Julius Adams.

Committee on Meeting Places—C. S. Sutton, Chairman, J. S. Dunn.

Sign Committee—H. McGibbin, Chairman, L. P. Adams.

Golf Committee—J. J. Gelz, Chairman.

NORTHERN MINNESOTA MEDICAL ASSOCIATION

The annual meeting of the Northern Minnesota Medical Association will be held in Duluth, Monday and Tuesday, August 4 and 5, 1924, in the auditorium of St. Mary's Hospital. The forenoons will be given to clinics, the scientific program being held each afternoon. Guests at the meeting will be entertained at a banquet Monday evening.

Clinics for the morning sessions have been arranged as follows:

Monday, August 4th, 8 A. M. to 12:30 P. M.—

Surgical Clinic:

Dr. T. L. Chapman

Dr. W. A. Coventry

Internal Medicine:

Dr. S. H. Boyer

Dr. F. W. Spicer

Dr. L. L. Merriman

Pediatric Clinic:

Dr. O. W. Rowe

Dr. C. O. Kohlbray

Orthopedic and Associated Clinics:

Dr. J. R. Kuth

Dr. B. F. Davis

Tuesday, August 5th, 8 A. M. to 12:30 P. M.:-

Internal Medicine Clinic:

Dr. E. L. Tuohy
Dr. T. R. Martin
Dr. F. J. Hirschboeck
Dr. P. G. Boman

Surgical Clinic:

Dr. A. N. Collins
Dr. A. J. Braden
Dr. A. L. McDonald

Surgical and Obstetrical Clinic:

Dr. J. R. Manley
Dr. W. R. Bagley

Skin and Genito-urinary Clinic:

Dr. E. Z. Shapiro
Dr. M. A. Nicholson

The following papers will be given at the afternoon sessions:

Address—Dr. Willard Bartlett, St. Louis, Mo.

"Forms of Organotherapy Which Have Proven to Be of Unquestionable Value." Dr. L. G. Rowntree, Rochester.

Address—Dr. C. N. Callander, Fargo, N. D.

"Acute Appendicitis." Dr. Theo. Bratrud, Warren.
Discussion: Dr. R. E. Farr, Minneapolis.

"Care and Treatment of Nephritis in Children." Dr. F. W. Schlutz, Minneapolis.

"Indications for Surgery in Duodenal Ulcer." Dr. Verne S. Cabot, Minneapolis.

"The Common Cold." Dr. F. W. Briggs, Duluth.

"Intestinal Parasites." Dr. M. A. Shillington, St. Paul.

"Fractures of the Hip." Dr. M. S. Henderson, Rochester.

"Some Little Appreciated But Valuable Therapeutic Measures." Dr. G. S. Wattam, Warren.

"Reminiscences of Thirty Years Ago." Dr. P. G. Cowling, Evansville.

"Fatigue in the School Child." Dr. Max Seham, Minneapolis.

"Diagnosis and Treatment of Upper Urinary Tract Obstruction." Dr. F. E. B. Foley, St. Paul.

Address—Dr. G. B. New, Rochester.

Address—Dr. H. Gideon Wells, Chicago, Ill.

"Some Phases of Epilepsy." Dr. E. M. Hammes, St. Paul.

"The History and Present Status of the Non-surgical Treatment of Hemorrhoids." Dr. W. A. Fansler, Minneapolis.

THE BRITISH ASSOCIATION FOR THE ADVANCEMENT OF SCIENCE

This Association, which meets annually, will convene in Toronto in August. The purpose of the association is to further "systematic direction to scientific inquiry" and "to promote the intercourse of those who cultivate science in different parts of the British Empire." Meetings are held annually in England and from time to time in various parts of the Empire. It last convened in Canada in 1909. The average enrollment for the 83 years previous to 1920 was 2,330.

The organization comprises thirteen sections. Those on Chemistry, Physiology and Psychology should be of

particular interest to the medical profession. Among the subjects that will be discussed are:

Advances made in our knowledge of disease.

Studies in visceral reflexes.

On the tactile sensory reflex.

Fractionate contractions in premature ventricular systoles in mammalian hearts.

Physiological and psychological factors of muscular efficiency in industry.

Vitamines and the relation of light to their action.

The respiratory quotient.

Insulin.

The list of those who will appear on the program includes the following names: H. H. Dale, A. B. Macallum, W. B. Cannon, Robert Kennedy, G. H. Parker, P. A. Shaffer, L. B. Mendel, T. B. Osborne, and D. D. Van Slyke.

The Physiology section will commence on Thursday, August 7. Physicians may obtain annual membership entitling them to convention privileges for the modest sum of \$5.00 sent to the local Hon. Treasurer, British Association, Room 50, Physics Bldg., University, Toronto. Additional information may be obtained from the local secretary at the same address.

REDWOOD-BROWN COUNTY MEDICAL SOCIETY

The annual meeting of the Redwood-Brown Medical Society was held at Sanborn, June 20, 1924. Officers elected for the following year were: President, Dr. J. Adams, Morgan; vice president, Dr. Theo. F. Hammermeister, New Ulm; secretary-treasurer, Dr. William A. Meierding, Springfield. Dr. F. D. Gray of Marshall was elected to act as delegate to the annual meeting of the State Medical Association in St. Cloud, with Dr. George B. Weiser, New Ulm, as alternate.

LYMANHURST AND PARKVIEW STAFF MEETING

The regular monthly meeting of the Lymanhurst and Parkview medical staffs will be held at the Lymanhurst School, 1800 Chicago Avenue, Minneapolis, Tuesday evening, August 26, at 7:00 o'clock.

The following program will be given:

"Review of Chemistry of Tuberculosis," Dr. W. P. Larson.

"Review of Calmet's Recent Work in Tuberculosis," Dr. W. P. Larson.

"Recent Developments in Bacteriology and Serology in Tuberculosis," Dr. Montank.

"The Pathology of Tuberculosis," Dr. Kano Ikeda.

All persons interested in tuberculosis are invited to attend these meetings and participate in the discussions.

INTER-STATE POST-GRADUATE ASSEMBLY

The Inter-State Post-Graduate Assembly, directed by the Tri-State District Medical Association, extends a hearty invitation to the physicians of America who are in good standing in their State or Provincial Societies to attend the annual assembly, which is to be held at Milwaukee, Wisconsin, October 27th, 28th, 29th, 30th and 31st, five full days of post-graduate work.

Among the eminent members of the profession and citi-

zens who have accepted places on the program are the following:

Dr. Nicholas Murray Butler, President of Columbia University, New York, N. Y.

Sir Arthur William Currie, President of McGill University, Faculty of Medicine, Montreal, Canada.

Merritte W. Ireland, Surgeon-General of United States Army, Washington, D. C.

Monsieur J. Jusserand, French Ambassador to United States, Washington, D. C.

Edward E. Stitt, Surgeon-General of United States Navy, Washington, D. C.

Professor Theodore Tuffier, Prof. of Surgery, Faculty of Medicine, Paris, France.

Dr. John V. Barrow, Los Angeles, California.

Dr. W. F. Braasch, Mayo Clinic, Rochester, Minnesota.

Dr. George E. Brewer, Emeritus Prof. of Surgery, Columbia University, College of Physicians and Surgeons, New York, N. Y.

Dr. Alan Brown, Prof. of Pediatrics, University of Toronto, Faculty of Medicine, Toronto, Canada.

Dr. Ralph C. Brown, Assistant Prof. of Medicine, Rush Medical College, Chicago, Illinois.

Dr. C. Macfie Campbell, Prof. of Psychiatry, Harvard University, School of Medicine, Cambridge, Massachusetts.

Dr. Walter T. Connell, Prof. of Medicine, Queen's University, Faculty of Medicine, Kingston, Canada.

Dr. John F. Cowan, Prof. of Surgery, Stanford University, School of Medicine, San Francisco, California.

Dr. George W. Crile, Prof. of Surgery, Western Reserve University, School of Medicine, Cleveland, Ohio.

Dr. Samuel J. Crowe, Clinical Prof. of Laryngology, Johns Hopkins University, School of Medicine, Baltimore, Maryland.

Dr. LeRoy Crummer, Prof. of Medicine, University of Nebraska, College of Medicine, Omaha, Nebraska.

Dr. Walter E. Dandy, Associate Prof. of Surgery, Johns Hopkins University, School of Medicine, Baltimore, Maryland.

Dr. William Darrach, Dean and Associate Prof. of Surgery, Columbia University, College of Physicians and Surgeons, New York, N. Y.

Dr. Vernon C. David, Assistant Prof. of Surgery, Rush Medical College, Chicago, Illinois.

Dr. David J. Davis, Prof. of Pathology and Bacteriology, University of Illinois, School of Medicine, Chicago, Illinois.

Dr. John B. Deaver, Prof. of Surgery, University of Pennsylvania, School of Medicine, Philadelphia, Pa.

Dr. Laurence R. DeBuys, Prof. of Pediatrics, Tulane University, School of Medicine, New Orleans, Louisiana.

Dr. George F. Dick, Assistant Prof. of Medicine, Rush Medical College, Chicago, Illinois.

Dr. Charles A. Elliott, Prof. of Medicine, Northwestern University, School of Medicine, Chicago, Illinois.

Dr. Leonard W. Ely, Prof. of Surgery, Stanford University, School of Medicine, San Francisco, California.

Dr. Joseph Evans, Prof. of Medicine, University of Wisconsin, School of Medicine, Madison, Wisconsin.

Dr. A. MacKenzie Forbes, Clinical Prof. of Orthopedics, McGill University, Faculty of Medicine, Montreal, Canada.

Dr. William Goldie, Associate Prof. of Medicine, University of Toronto, Faculty of Medicine, Toronto, Canada.

Dr. Marvin L. Graves, Prof. of Medicine, University of Texas, School of Medicine, Galveston, Texas.

Sir Henry Gray, Royal Victoria Hospital, Montreal, Canada.

Dr. Don M. Griswold, Prof. and Head of Department of Preventive Medicine and Hygiene, State University of Iowa, Iowa City, Iowa.

Dr. Garfield M. Hackler, Prof. of Surgery, Baylor University, School of Medicine, Dallas, Texas.

Dr. John A. Hartwell, Associate Prof. of Surgery and Clinical Surgery, Cornell University, Medical College, New York, N. Y.

Dr. Carl A. Hedblom, Prof. of Surgery, University of Wisconsin, School of Medicine, Madison, Wisconsin.

Dr. William B. Hendry, Prof. of Obstetrics and Gynecology, University of Toronto, Faculty of Medicine, Toronto, Canada.

Dr. Russell D. Herrold, McCormick Institute for Infectious Diseases, Chicago, Illinois.

Dr. Julius H. Hess, Prof. of Pediatrics, University of Illinois, School of Medicine, Chicago, Illinois.

Dr. Russell A. Hibbs, Prof. of Orthopedic Surgery, Columbia University, College of Physicians and Surgeons, New York, N. Y.

Dr. Frederick J. Kalteyer, Associate Prof. of Medicine, Jefferson Medical College, Philadelphia, Pennsylvania.

Dr. Allen B. Kanel, Prof. of Surgery, Northwestern University, School of Medicine, Chicago, Illinois.

Dr. Ralph A. Kinsella, Associate Prof. of Medicine, University of St. Louis, School of Medicine, St. Louis, Missouri.

Dr. Francis H. Lahey, Prof. of Clinical Surgery, Harvard University, School of Medicine, Boston, Massachusetts.

Dr. Dean Lewis, Prof. of Surgery, Rush Medical College, Chicago, Illinois.

Dr. LeRoy Long, Dean and Prof. of Surgery, University of Oklahoma, School of Medicine, Oklahoma City, Oklahoma.

Dr. William E. Lower, Prof. of Urology, Western Reserve University, School of Medicine, Cleveland, Ohio.

Dr. Charles B. Lyman, Prof. of Clinical Surgery, University of Colorado, School of Medicine, Denver, Colorado.

Dr. N. J. MacLean, Associate Prof. of Surgery, University of Manitoba, Faculty of Medicine, Winnipeg, Canada.

Dr. Ralph H. Major, Prof. and Head of Department of Medicine, University of Kansas, School of Medicine, Rosedale, Kansas.

Dr. Charles H. Mayo, Mayo Clinic, Rochester, Minnesota.

Dr. William J. Mayo, Mayo Clinic, Rochester, Minnesota.

Dr. Edward Miloslavich, Director of Department of Pathology and Bacteriology, Marquette University, School of Medicine, Milwaukee, Wisconsin.

Dr. Roger S. Morris, Prof. of Medicine, University of Cincinnati, School of Medicine, Cincinnati, Ohio.

Dr. Bernard H. Nichols, Department of Roentgenology, Cleveland Clinic, Cleveland, Ohio.

Dr. Walter L. Niles, Dean and Prof. of Clinical Medicine, Cornell University, School of Medicine, New York, N. Y.

Dr. Dallas B. Phemister, Assistant Prof. of Surgery, Rush Medical College, Chicago, Illinois.

Dr. William F. Petersen, Associate Prof. of Pathology and Bacteriology, University of Illinois, School of Medicine, Chicago, Illinois.

Dr. Harry M. Richter, Prof. of Surgery, Northwestern University, School of Medicine, Chicago, Illinois.

Dr. Stanley P. Reimann, Director of Laboratories, Lankenau Hospital, Philadelphia, Pennsylvania.

Dr. David Riesman, Prof. of Clinical Medicine, University of Pennsylvania, School of Medicine, Philadelphia, Pennsylvania.

Dr. Milton J. Rosenau, Prof. of Preventive Medicine and Hygiene, Harvard University, School of Medicine, Boston, Massachusetts.

Dr. E. C. Rosenow, Mayo Clinic, Rochester, Minnesota.

Dr. G. W. Stevens, Milwaukee, Wisconsin.

Dr. Wallace Irving Terry, Prof. of Surgery, University of California, School of Medicine, San Francisco, California.

Dr. John H. J. Upham, Prof. and Head of Department of Medicine, University of Ohio, School of Medicine, Columbus, Ohio.

Dr. George Gray Ward, Jr., Prof. of Obstetrics and Gynecology, Cornell University, School of Medicine, New York, N. Y.

Dr. Louis M. Warfield, Prof. of Internal Medicine, University of Michigan, School of Medicine, Ann Arbor, Michigan.

Dr. George Weaver, McCormick Institute for Infectious Diseases, Chicago, Illinois.

Dr. Charles J. White, Prof. of Dermatology, Harvard University, School of Medicine, Boston, Massachusetts.

Dr. Charles S. Williamson, Prof. of Medicine, University of Illinois, School of Medicine, Chicago, Illinois.

Dr. Milton C. Winternitz, Dean of Yale University, School of Medicine; Prof. of Pathology and Bacteriology, New Haven, Connecticut.

Dr. John A. Witherspoon, Prof. of Medicine, Vanderbilt University, Medical Department, Nashville, Tennessee.

Dr. John L. Yates, Milwaukee, Wisconsin.

Dr. Hugh H. Young, Clinical Prof. of Urology, Johns Hopkins University, Medical Department, Baltimore, Maryland.

Dr. Abraham Zingher, Assistant Prof. of Hygiene, University and Bellevue Hospital, Medical College, New York, N. Y.

This Association is supervising an Inter-State Post-Graduate Clinic Tour to Canada, British Isles and France, to start May 18, 1925. Leading teachers and clinicians of Canada and Europe will arrange and conduct clinics and demonstrations in the following clinic cities: Toronto and Montreal, Canada; London, Liverpool, Leeds, Manchester and Newcastle, England; Edinburgh and Glasgow, Scotland; Dublin and Belfast, Ireland; Paris, Lyons and Strasbourg, France.

Besides the main tour, special tours to practically all the leading centers of Europe will be arranged. Sightseeing trips to all places of interest in the countries visited will be included in the regular tour.

The cost of the tour, including first-class hotels, board, steamship, clinic arrangements and all ordinary traveling expenses, will be under \$1,000.00. The tour is open to

physicians in good standing in their State Societies, their families and friends who are not physicians.

Those desiring further information should communicate with the Managing Director, William B. Peck, Freeport, Illinois.

WABASHA COUNTY MEDICAL SOCIETY

The fifty-sixth annual meeting of the Wabasha County Medical Society was held at Lake City, Minnesota, Thursday, July 10, 1924.

Following the business session a dinner was served at the Hotel Lyon at 1 P. M.

Papers presented at the afternoon session included:

President's Address, "Some Matters Pertaining to the Welfare of the Medical Profession." Dr. W. H. Repogle, Wabasha.

"Studies in Hepatic Function." Dr. C. H. Green, Surgical Section, Mayo Clinic, Rochester.

"Some Aspects of the Nephritis Problem." Dr. N. M. Keith, Medical Section, Mayo Clinic, Rochester.

Officers elected for the coming year are: President, Dr. H. E. Bowers, Lake City; vice president, Dr. R. S. Gutsell, Zumbro Falls; secretary-treasurer, Dr. W. F. Wilson, Lake City.

Resolutions were adopted favoring periodic health examinations, reasonable publicity regarding accomplishments and aims of scientific medicine, measures to control quacks and irregulars.

It was voted to hold the next meeting at Plainview, Minn.

OF GENERAL INTEREST

Dr. P. J. Griffin, lately of Detroit, Minn., recently moved to his former location at Fertile.

Dr. J. C. Rothenburg, Springfield, recently returned from a motor trip through Montana.

Drs. A. F. and Mary Strickler of Sleepy Eye have just returned from a tour of the western states.

Dr. R. B. Hullsiek, St. Paul, is associated with Dr. C. N. Hensel, 1014 Lowry Bldg., in the practice of internal medicine.

Eternal vigilance in the matter of vaccination seems to be necessary for the prevention of smallpox. From the first of the year until May 31st, 1,341 cases and 109 deaths have been reported in Detroit, Michigan.

Dr. H. L. Sargeant, who has just finished a two-year post-graduate course at the Mayo Clinic, Rochester, recently moved his family to Fergus Falls, where he is associated with Dr. O. T. Sherping and Dr. C. O. Estrem in the practice of his profession.

Dr. and Mrs. F. P. Strathern of St. Peter spent the latter part of June and the first of July in Chicago and Battle Creek, Michigan, where Dr. Strathern took advantage of the opportunity to make a study of interpretation of x-rays of the chest and abdomen.

Dr. R. C. Webb, Minneapolis, read a paper on "Fractures of the Tibia and Fibula" before the Great Northern Railroad Surgeons Association at Spokane, Washington, June 24, 1924. Dr. Webb also attended the Northwestern

Medical Association meeting in Vancouver, B. C., June 26 to 28.

In a recent address, Dr. Banting related how the observation by Dr. Moses Barron of Minneapolis of the effect of experimental ligation of the pancreatic duct led to the deduction that by this means it might be possible to eliminate the products of the acinous cells and obtain the product of the islets. Thus is research founded upon research.

Resignation of Miss Louise M. Powell as director of the School of Nursing, University of Minnesota, and of Dr. LeRoy A. Calkins, as assistant professor of Gynecology and Obstetrics, were recommended to the president of the Administrative Board of the Medical School at a meeting held June 23, 1924. The secretary was instructed to convey to both the expression of the regret and appreciation of the Administration Board.

The following nominations were approved and recommended at the May meeting of the Administrative Board of the Medical School, University of Minnesota: Dr. Frank W. Stevenson, as Assistant in Medicine; Dr. G. R. Kamman, as Assistant in Nervous and Mental Diseases; Dr. H. W. Grant, as Assistant in Ophthalmology and Otolaryngology; Dr. A. N. Noran, as Assistant in Pediatrics. The resignation of Dr. A. L. Kusske as refractionist was accepted and nomination was made of Dr. Harold J. Goss to fill the vacancy.

Under the sponsorship of the Illinois State Medical Society there is in preparation "A History of Medical Practice in the State of Illinois" that must go to the printer at an early date. In order that this volume may be accurate and complete, all possible assistance is asked from every source, as to personal data and experiences, including diaries, photographs and similar documentary momentoes of pioneer Illinois doctors and of progressive phases of medical practice, as well as of achievements in fields other than those of medical science. Prompt return in good condition is promised for anything loaned the committee, the personnel of which is:

O. B. Will, M.D., Peoria, Ill.
C. B. Johnson, M.D., Champaign, Ill.
Carl E. Black, M.D., Jacksonville, Ill.
George A. Dicus, M.D., Streator, Ill.
James H. Hutton, M.D., Chicago, Ill.
Chas. J. Whalen, M.D., Chicago, Ill., Chairman

The scope of the volume will range from the discovery of Illinois to modern times. Through this period of over 250 years there is much of thrilling interest to be detailed. Collection of the human interest data can come only from the families or closest friends of the pioneers, many of whom long ago removed to distant sections of the United States.

Some of the subjects touched will be: Physicians accompanying early explorers; government surgeons and physicians in attendance at the forts; early medicine in Illinois; theories of healing from the days of the Aborigines through the mound-builders; French and English explorers; the ante-boundary days; sporadic settlers; medical attendants for the covered wagon; herb doctors; primitive surgery; medicine and missionaries; migration of pioneer physicians to new territory; the "circuit-riding"

and "saddle-bag" doctors and their burdens, triumphs and perils; pioneers as "utility citizens"; Illinois men in war time—there are four conflicts to be considered since the opening of the Nineteenth Century; Illinois medical men away from medicine, i.e., in industry, in science, in belles-lettres—art, music and literature. Will any and all doctors, former residents of Illinois, or descendants of pioneer physicians of the "Illinois country," communicate at once with the Committee on Medical History, Illinois State Medical Society, 6244 North Campbell Avenue, Chicago, Illinois?

NEW AND NON-OFFICIAL REMEDIES

The following articles have been accepted by the Council on Pharmacy and Chemistry:

ABBOTT LABORATORIES:

Benzyl Fumarate

DESHELL LABORATORIES:

Petrolagar

Petrolagar (Unsweetened)

Petrolagar (with Phenolphthalein)

Petrolagar (Alkaline)

HOFFMANN-LA ROCHE CHEMICAL WORKS:

Digalen-Roche (Cloetta)

Ampules Digalen-Roche (Cloetta), 1.1 c.c.

Tablets Digalen-Roche (Cloetta)

Hypodermic Tablets Digalen-Roche (Cloetta)

Oleo-Bi-Roche

Ampules Oleo-Bi-Roche, 2 c.c.

MEAD JOHNSON AND COMPANY:

Mead's Cod Liver Oil

H. A. METZ LABORATORIES:

Sulpharsphenamine-Metz in 0.05, 0.075, 0.1, 0.15, 0.3, 0.45, 0.6 gm. ampules.

FREDERICK STEARNS AND COMPANY:

Insulin-Stearns

Insulin-Stearns Single Strength

Insulin-Stearns Double Strength

NEW AND NON-OFFICIAL REMEDIES

Neutral acriflavine-Abbott, 0.1 Gm. Ampules.—Each ampule contains 0.1 gm. neutral acriflavine-Abbott (see New and Non-official Remedies, 1924, p. 24). The Abbott Laboratories, Chicago.

Insulin-Stearns.—A brand of insulin. For a discussion of the actions, uses and dosage, see New and Non-official Remedies, 1924, p. 149. Insulin-Stearns is marketed: insulin-Stearns, single strength (5 c.c. vials containing 10 units in each c.c.), and insulin-Stearns, double strength (5 c.c. vials containing 20 units in each c.c.). Frederick Stearns and Co., Detroit.

Digalen-Roche (Cloetta).—A sterile solution containing in each c.c. 0.3 mg. of an active derivative of digitalis as isolated by Cloetta, containing 7.5 per cent of alcohol. The actions and uses of digalen-Roche (Cloetta) are the same as those of digitalis. The average dose is from 1 to 2 c.c. (15 to 30 minims). The maximum daily dosage is 6 c.c. (90 minims). Digalen-Roche (Cloetta) is also suitable for intramuscular and intravenous injection. Intravenous injections of 1 c.c. (15 minims) may be repeated at intervals

of one-half to one hour as necessary. Digalen-Roche (Cloetta) is also marketed as follows: ampules digalen-Roche (Cloetta), 1.1 c.c.; tablets digalen-Roche (Cloetta) (equivalent to digalen-Roche (Cloetta) 0.5 c.c.); hypodermic tablets digalen-Roche (Cloetta) (equivalent to digalen-Roche (Cloetta), 1 c.c.). The Hoffman-La Roche Chemical Works, New York. (Jour. A. M. A., June 14, 1924, p. 1937.)

Petrolagar.—A mixture composed of liquid petrolatum 65 c.c., agar 10 gm., sugar and flavoring 2 gm., sodium benzoate 0.1 gm., water to make 100 c.c. Petrolagar has the actions of liquid petrolatum. It is claimed that the emulsification of the liquid petrolatum increases its efficiency, and that the agar adds soft bulk and tends to increase peristalsis. The average dose of petrolagar is 15 c.c. morning and night. Petrolagar is also marketed in the form of petrolagar (unsweetened), containing no sugar. petrolagar (with phenolphthalein), containing 0.33 gm. phenolphthalein per 100 c.c., petrolagar (alkaline), containing milk of magnesia 25 c.c. per 100 c.c. The Deshell Laboratories, Inc., Los Angeles. (Jour. A. M. A., June 28, 1924, p. 2119.)

PROPAGANDA FOR REFORM

Chologogues.—As early as 1868, a British committee appointed to investigate the subject arrived at the conclusion that mild mercurous chlorid (calomel), mercuric chlorid and taraxacum—all reputed chologogues—do not increase the flow of bile but probably act on the bile-expelling apparatus. Recently the latest experimental procedure was applied to judge the status of a number of substances that have at various times been alleged to influence bile flow. With the exception of bile salts, negative results only were obtained with such substances as calomel and salicylates. All dependable evidence warrants the recommendation that clinicians consider the advisability of abandoning therapeutic efforts to "stimulate" the liver through the use of substances having alleged chologogic effects. (Jour. A. M. A., June 7, 1924, p. 1867.)

Gly-So-Iodonate.—A few months ago the Council on Pharmacy and Chemistry published a report on an alleged bactericide "Gly-So-Iodonate." The product is put on the market by a company whose name is much more imposing than its importance warrants—"The National Medical Research Laboratories" of Milwaukee, earlier known as the "Wisconsin Medical Laboratories." Charles E. Hutchings, who claims to be a "medical man," seems to have been the prime mover in putting "Gly-So-Iodonate" on the market. Hutchings, in letters, has stated that he is a "graduate of Kings College of London" and has claimed that he is a "member of Marquette Medical College." However, an inquiry directed to Kings College of London brought the reply that they had no record of a man of this name on the medical register. The Marquette University School of Medicine seems to be equally ignorant of Hutchings' connection with that institution. After the Council's report had been published, the National Medical Research Laboratories sent broadcast a six-page circular, three pages of which were devoted to what purported to be a "Partial List of Representative Industries Protecting Their Many Thousands of Employees from Infection With G-S-I." As it seemed reasonable to suppose that a concern which published a misleading formula for its product would be quite as likely

to publish misleading references for the value of its product, some of the "representative industries" listed by the exploiters of "G-S-I" were written to. From the replies which were received, it seems evident that the basis for at least some of the references published by the exploiters of Gly-So-Iodonate rests on as flimsy a foundation as the alleged formula of the stuff and the educational claims of Charles E. Hutchings. (Jour. A. M. A., June 7, 1924, p. 1881.)

Morphin Addiction.—The so-called withdrawal symptoms which arise in those who have become accustomed to large doses of morphin are well known to all practitioners who are compelled to deal with such habitués. To account for these symptoms it has been alleged that the continuous taking of morphin causes the presence in the blood serum of a substance having a protective effect against this drug. However, it has been shown that the blood of a tolerant animal does not contain any protective substance against morphin, nor was there any substance capable of conferring any immunity to the toxic action of morphin on an animal into which it is injected detected in the blood serum of a human being who has acquired a high tolerance to morphin. Also, it has been proven that a specific toxic substance is not produced by habituation to morphin. Since some methods of treating drug addiction have been based on the belief that a toxic substance is formed, the time has arrived for seeking a new point of departure in the explanation of the various manifestations that are presented by drug addicts. (Jour. A. M. A., June 14, 1924, p. 1976.)

Whittington's Consumption Cure a Fraud.—The postal authorities have closed the mails to Frederick Graham and the Tuberculosis Home Remedy Company by the issuance of a fraud order. The Whittington "Cure" was the subject of a report in The Journal of the American Medical Association in 1916; analysis in the A. M. A. Chemical Laboratory at that time showed it to be a flavored syrup devoid of any potent ingredients except alcohol. The evidence brought out in the hearing by the Post Office authorities showed that the preparation was claimed to contain sugar, glycerin, alcohol and the extract matter from *pyrus malus folia* (apple leaves), gentian root, *rhamnus purshiana* (cascara) and licorice root. Analyses in the Bureau of Chemistry of the Department of Agriculture indicated the absence of gentian and the presence of only traces of cascara and licorice. No evidence was submitted to show how apple leaves had come to be hit upon as a "cure" for tuberculosis. (Jour. A. M. A., June 14, 1924, p. 1933.)

Atussin, Peptoproteasi, Paraganglina Vassale, Fosfoplasmina, Asmoganglina and Endo-Ovarina Tablets Not Accepted for N. N. R.—These products are manufactured in Italy and sold in the United States by the Neother Products Co., New York. Atussin is claimed to be a suprarenal preparation; Peptoproteasi, a gastric ferment preparation; Paraganglina Vassale, a suprarenal product; Fosfoplasmina, an egg yolk extract; Asmoganglina, an extract of the suprarenal and hypophysis, and Endo-Ovarina Tablets, an ovary preparation. In each case the statements made in regard to composition were indefinite and the therapeutic claims unwarranted. The booklet which the Neother Products Co. uses as advertising for these products consists of 151 pages, presents a jumble of fact and fancy, and reads more like a

patent medicine almanac than a scientific treatise. The Council on Pharmacy and Chemistry found Atussin, Peptoproteasi, Paraganglina Vassale, Fosfoplasmina, Asmoganglina and Endo-Ovarina Tablets unacceptable because: (1) their composition is indefinite or semisecret; (2) the therapeutic claims are unwarranted, and (3) their recognition would be the means of advertising proprietary products which are not accepted. (Jour. A. M. A., June 21, 1924, p. 2068.)

ACUTE PELVIC ABSCESS IN CHILDREN: Philip Rosenblum and Ralph E. Bettman (Amer. Journal of Diseases of Children, April, 1924). The author reports three cases of acute pelvic abscess formation, with relief of symptoms in each case after drainage. In the first two, this occurred spontaneously through the vagina and in the third case artificially by operation. In the third case the cause of the abscess was proved to be not the appendix, and it probably did not originate from the internal genitalia, which were palpated and found to be normal. The abscess possibly originated from the retroperitoneal structures and was presumably of glandular origin. The frequent association of abdominal pain with throat conditions in childhood, recently brought to our attention by Brennemann, is new to us. Some pelvic abscesses might be from just such infections involving the lymph glands which break down. He is absolutely at a loss to explain the source otherwise. They were not appendiceal abscesses. These, of course, may rupture spontaneously, but they almost invariably rupture into the bowel. A spondylitis might give rise to a pelvic abscess but no signs or symptoms pointing to spinal origin were present, nor in such cases would the patients be apt to recover spontaneously. The fact that all three cases occurred in female patients, and that in two there was a discharge of pus from the vagina, might point to the genitalia as the source. Pyosalpinx has been known to occur in infants, and must be considered as a possible etiologic factor.

R. N. ANDREWS.

UBER INTRAPERITONEALE BLUT TRANSFUSION-EN: L. F. Meyer (Jahrb. f. Kinderheilkunde, Mar. 5, 1924, s. 188-200). Meyer has used the intraperitoneal method of giving citrated blood in 25 cases. He uses this method in any case in which a transfusion is indicated. His technique differs in one important point from the original procedure introduced by us. He has not found it necessary to group his donor and recipient and has not observed any ill effects. If this is substantiated by further clinical re-

ports, it materially enhances the value of intraperitoneal transfusions. Meyer concludes that the results obtained from intraperitoneal transfusion are equivalent to those following direct intravenous transfusion.

DAVID SIPERSTEIN.

KLINISCHE UND EXPERIMENTELLE BEWEISE FUR DIE LEBENSFAHIGKEIT TRANSFUNDIERTER KORPERFREMDER ERYTHROCYTEN: Hañs Opitz (Monatschr. f. Kinderheilk., Bd. 27, Jan., 1924, Heft. 4, pp. 376-384). Opitz concludes, from an extensive series of clinical cases, that large transfusions of blood are especially suitable for the anemias of infancy. He considers the transfusion a means of introducing active and functional blood cells into the patient's circulation. The intravenous injection of plasma alone produced no rise in blood values, while the introduction of washed red blood cells caused a proportionate rise in the erythrocyte count. He finds that the injected blood does not act as a stimulative agent and as "building material" for new red cells, but that the injected cells actually function. His clinical data are, however, too accurate to be convincing to the reviewer.

DAVID SIPERSTEIN.

UBER ANEMIA PERNICIOSA UND PERNICIOSA-AHNLCHE ANEMIEN IM KINDESALTER: Hotz, A. (Jahr. f. Rinderh., Mar. 5, 1924, pp. 161-181). Hotz reports a case of pernicious anemia in a girl of 10, diagnosed by Nægeli. The patient presented typical clinical and hematological findings.

He also reports 2 very interesting cases of anemia of the pernicious type, who clinically presented a typical picture of a severe chronic digestive insufficiency (Herber's Infantilism). The clinical findings differentiate these cases from a true pernicious anemia. Furthermore, in one of his cases, the blood findings were characteristic of a secondary anemia, except at the height of the anemic stage.

DAVID SIPERSTEIN.

TUBERCULOSIS IN INFANCY—ITS PROGNOSIS AND PREVENTION: G. Albert Davis (Arch. of Ped., March, 1924). Tuberculosis in infants has always been considered a more or less hopeless condition. In a series of 114 cases under two years studied by Brown, the mortality was 70 per cent. Fishberg states that at least one out of three tuberculosis infected infants lives. It must be thoroughly understood, however, that we are speaking of cases which show tuberculous infection as evidenced by positive skin tests, and we are not limiting ourselves to cases showing symptoms of tuberculosis. Thus it is seen that tuberculous infection in infants under two years is not the virulent disease that it was previously considered. Under one year of age it is still a very severe infection with the chances against recovery, but not so in the age period between one and two years. In 77 per cent of our cases there was a definite history of exposure to a case of tuberculosis. This is the vulnerable point. Where the diagnosis is doubtful, as so frequently occurs, it is a wise precaution to give the infant the benefit of the doubt, and remove it from the questionable environment.

MAYO CLINIC, ROCHESTER

FUNDAMENTAL FACTS RELATIVE TO THE STUDY OF THE VERTEBRÆ IN INDUSTRIAL ACCIDENT CASES: George and Leonard (Radiology, April, 1924). This article presents a discussion of the roentgen findings in the vertebræ in relation to industrial work. An attempt has been made to describe clearly the average normal vertebra with a plate of a reconstructed skeleton as a key.

A number of normal variations in the vertebra are common. Among the most important are: (1) Bifid laminae of the 5th lumbar; (2) sacralization of the 5th lumbar; (3) rudimentary rib on the 12th thoracic or enlarged transverse process on the first lumbar. All of these variations, in their opinion, have no clinical significance whatever.

Certain changes occur in the vertebra which they classify as: (1) Chronological, (2) Occupational, (3) Postural. These include scoliosis, hypertrophic, and sclerotic changes, which they believe probably are not due to injury at all, and certainly not to one single injury. They believe these changes occur normally with age and as the result of a particular occupation.

Under the effects of injury to the vertebræ they classify:

- (1) Compression fracture of the body with few clinical and no neurological symptoms, followed by complete recovery.
- (2) Compression of the body with comminution with more symptoms and a less favorable prognosis.
- (3) Compression or comminution or both with a dislocation accompanied by very serious manifestations.
- (4) Simple dislocation without any visible fracture.
- (5) Kummell's disease, which is a rarefaction of the body of the vertebra gradually producing a wedge shape, believed by Kummell to follow injury after a long period of time. George and Leonard believe this occurs in older people and probably has no direct relationship to any recent injury.

They note that no matter how severe a fracture is, complete obliteration of the intervertebral space never occurs. They do not believe that complete fusion of two bodies can ever occur following injury. The body of the 5th lumbar vertebra is rarely compressed but the transverse processes are frequently broken.

Considerable detail is given to the discussion of fractures of the atlas and axis. The authors describe their method of determining malposition by drawing parallel lines connecting points on the atlas and axis. Distortion of these lines indicates some injury.

The authors doubt very seriously that spondylolisthesis is always due to injury because they have seen it frequently without injury, and also have observed it in patients who had no symptoms. They feel that more proof is needed before the roentgenologist can state in a report that spondylolisthesis has been due to injury.

The clinical use of the term "sacro-iliac dislocation" is sharply criticized. It requires extreme direct violence to produce this actually, and they have seen it only rarely in cases wherein it followed simply stooping or lifting. They note that the clinical diagnosis is made practically always without real x-ray substantiation. Sacro-iliac separation, that is a lateral separation, occurs. It is best seen in females with repeated pregnancies. This is not a dislocation, however.

The hypertrophic changes which occur with age are confusing in the interpretation of plates following injury. It is possible that local hypertrophic changes between two vertebræ may be the result of an injury, but even this has not been proven. The general hypertrophic changes they feel certain have no relationship to one injury. Acute osteomyelitis may be followed by new bone formation which simulates local hypertrophic changes. They attempt to distinguish true infectious arthritis from these hypertrophic changes by the fact that the new bone formation following the former condition is located on the lateral margins of the vertebra while the pathology of the latter condition is located on the anterior margin of the vertebra.

They emphasize that complete fusion of two vertebræ is always due to an infectious process, most often tuberculosis or a congenital anomaly. Tumors and syphilitic changes are rarely met with in industrial cases.

LEO G. RIGLER, M.D.

X-RAY DIFFERENTIAL DIAGNOSIS IN PULMONARY TUBERCULOSIS: H. L. Sampson (Trudeau Sanatorium, Annual Report 23). Inasmuch as analysis of roentgenograms lies in one's ability to understand the reasons for normal or abnormal shadows, one must necessarily acquaint himself with roentgenograms of the theoretically normal parts under consideration. It is true that the theoretically normal, in the case of lungs, may vary within wide limits. However, that should not deter us in attempting to standardize such a normal, bearing in mind that time and accumulation of knowledge may tear down our previous concepts.

In the normal lungs we have two fields traversed by many linear markings radiating from two central points. That all of this arborization is the result of shadows cast by pulmonary systems, viz.: vascular, bronchial and lymph, is probably accepted by all. That one system, the vascular, contributes mostly to these shadows can probably be demonstrated. It is also quite probable that the bronchial "tree" plays an important part, but ordinarily it is very difficult to "identify." The lymph channels also go unrecognized as such.

These said "trees" or linear markings start from a root and continue peripherally in a more or less uninterrupted fashion until the periphery is almost reached, becoming more delicate in consequence of their diminishing size. Any gross interference with this linear appearance obviously would suggest anatomical abnormality or a pathological change in the lung.

In the theoretically normal lung, we may find at the root a density or two, or possibly in the lung field a shadow or two of a similar character, only usually smaller, or a localized increase in the shadow, producing value of some of the linear markings. The question then arises, how numer-

ous can these densities or the stage of exaggeration of the linear markings become before we can regard them as evidence of past or present pulmonary disease. For this reason the author has submitted a division of roentgenograms into the following groups:

1. The theoretically normal:

This would mean a roentgenogram void of any abnormal densities. As this probably rarely exists we can standardize the "normal" as having one or a few abnormal densities at the root with possibly an occasional density in the parenchymal field.

2. Doubtful group:

Under this we have: More numerous densities, the root shadow more pronounced, a general haze in a portion of the pulmonary field, a tenting or peaking of the diaphragm, a secondary shadow in the extreme apex immediately under the second rib posteriorly and referred to as a pleural cap, and finally a slight localized or general accentuation of pulmonary markings.

3. Positive group:

Obviously this group includes anything in excess of the foregoing groups, namely, coalescing of isolated densities, blotching, shadows, fans, mottling, speckling, gross exaggeration of linear markings, heavy homogeneous shadows.

The following terms are used:

1. Exaggerations of lung markings, doubtful or definite.
2. Stringlike shadows.
3. Mottling, fine or coarse.
4. Areas of rarefaction and annular shadows.
5. Homogeneous densities—localized or general light marked.

The possibility of identifying pulmonary tuberculosis lies in the ability to recognize the tubercle and its accompanying changes. The same reasoning may be applied to other pathological conditions in the lung, namely, that they may produce characteristic shadows. Pulmonary abscess many times gives a very classical picture, viz., a localized homogeneous density with an area or areas of rarefaction, a fluid level, etc.

Bronchiectasis or purulent bronchitis with its heavy markings to the base rarely with a fluid level in the bronchiectatic cavities gives also a somewhat familiar picture.

Malignancy having such a variety of forms gives pictures where a description is almost impossible. However, usually there are massive localized shadows or general homogeneous densities. This may also be the case with other common or rarer forms of pulmonary disease. J. R. FUCHLOW.

ROENTGEN-RAY THERAPY IN THE TREATMENT OF EXOPHTHALMIC GOITER: D. M. Goodwin, W. B. Long (Amer. Jour. of Med. Science, January, 1924) have made a study of the results obtained by roentgen-ray therapy in a series of selected cases of hyperthyroidism. They emphasized the fact that their report is submitted not particularly to recommend roentgen-ray therapy, but to record their observations on the clinical course of these cases of very definite toxic exophthalmic types. These cases all showed, in addition to the thyroid tumors, the usual symptoms of thyroid toxemia, namely, tachycardia, sweating, exophthalmus, loss of weight, and increased metabolism. With the exception of a few cases, all of these patients remained at home, following as closely as possible certain

directions as to rest, diet, etc. They reported at the clinic once a week, and on these visits a record was made of their weight, pulse rate and subjective symptoms. Frequent estimations of the basal metabolic rate were made.

The roentgen-ray technique consisted in the administration of approximately two-fifths of an erythema dose, filtered through aluminum, to alternate sides of the neck each week. The region to which the application was made embraced that part of the neck and thorax lying between the upper level of the thyroid and the upper level of the third rib. A uniform distance of 35 centimeters from the target to the skin was used. Filtration was accomplished by 3 millimeters of aluminum. The potential at the tube terminals was 140,000 volts each, corresponding to a spark gap of 10 inches between points. Five milliamperes were used, and the time of exposure was uniformly 5 minutes, with the exception that in highly toxic cases this dose was still further reduced. They state that such a dose as this may be given weekly to alternate sides of the neck for months without any evident permanent skin damage.

They include a series of five charts, showing the course of cases, with their recorded observations on the various symptoms, such as nervousness, sweating, palpitation, dyspnea, weakness, pulse, weight, and basal metabolism; also, the number of treatments and the dates on which they were given.

Examination of these charts gives the impression of very gratifying improvement under this type of therapy. There was a very definite increase in weight, with a very definite decline in the metabolism rate. The pulse curve usually showed a downward trend. The change produced in the subjective symptoms was marked, although the improvement in these cases was a matter of months. It usually took a period of five months before there was any impressive change.

However, all of the cases treated did not show the very satisfactory improvement in the subjective and objective symptoms, but apparently were uninfluenced by the therapy. One of these cases, in which the course of the disease apparently remained unchanged after a total of 22 treatments, became discouraged, and requested an operation. This gave an opportunity of studying the gland both macroscopically and microscopically. They point out that the operative technique was not rendered particularly difficult by the previous radiation. The microscopic examination showed no very definite changes which might be ascribed to the roentgen-ray, except the absence of dilated capillaries, which are found rather constantly in goiters of this type.

Besides the charts referred to, there are complete case reports in all of these cases.

In summarizing, they bring out the following points:

(1) In 5 of the 9 cases treated the results of treatment have been satisfactory.

(2) In 1 case the influence of treatment was doubtful, and in another no conclusion can be drawn because treatment was interrupted.

(3) In the 2 remaining cases the toxemia seemed to increase in spite of prolonged treatment.

(4) In the 5 favorable cases they were unable, as yet, to speak of the permanency of benefit or tendency to recurrence of symptoms.

DR. P. G. BOMAN.

BOOK REVIEWS

BOOKS RECEIVED FOR REVIEW

LIFE INSURANCE EXAMINATION. Frank W. Foxworthy, Ph.B., M.D., Indianapolis. Formerly Chairman Medical Section, American Life Convention, President American Association of Medical Examiners, etc. 738 pages. 156 illus. Cloth, \$9.00. St. Louis: C. V. Mosby Company, 1924.

MODERN METHODS OF TREATMENT. Logan Glendenning, M.D., Asst. Prof. of Medicine, Lecturer on Therapeutics, Medical Dept. Univ. of Kansas; Attending Physician Kansas City General Hospital, etc. Chapters on special subjects by H. C. Anderson, M.D., J. D. Cowherd, M.D., Carl O. Rickter, M.G., F. C. Neff, M.D., E. H. Skinner, M.D., and E. R. De Weese, M.D. 692 pages. Illus. Cloth, \$9.00. St. Louis: C. V. Mosby Co., 1924.

EAT YOUR WAY TO HEALTH. Robert Hugh Rose, A.B., M.D., Instructor Post Graduate Medical School, New York City. 264 pages. Cloth, \$2.00. New York: Funk & Wagnalls Company, 1924.

A DIABETIC MANUAL. Elliott P. Joslin, M.D., Clinical Professor of Medicine, Harvard University. 211 pages. Illus. 3rd edition, revised. Cloth, \$2.00. Philadelphia: Lea and Febiger, 1924.

This book, small compared to the one entitled "Treatment of Diabetes," by the same author, is still more pretentious than some of the other manuals for diabetic patients.

One of the greatest difficulties in the successful treatment of this disease is the education of the patient. How far that should go is subject to some difference of opinion. The more intelligent patients want extensive information and for them such a book as this is suitable. It is too complete, perhaps, for the average patient.

Included among the instructions for patients are numerous tables of great practical value in the treatment of this malady all included between the covers of one book. These include normal weights for children and adults and a very limited number of typical diets. Menus for a greater variety of combinations of food elements would have made the book more valuable to the profession.

The tables on food composition are very complete, including the so-called "diabetic foods," and are therefore of special value to the dietitian or physician who must so often be dietitian as well. The long list of diabetic recipes enables the patient to add variety to an otherwise sameness in diet.

RHUS DERMATITIS: Its Pathology and Chemotherapy. James B. McNair, Univ. of Chicago. 293 pages. 15 illus. 3 plates. Univ. of Chicago Press, 1923.

Poison ivy seems to have a special mission for spoiling vacations, and now that vacation time is here, attention turns toward the plant and its menace. Those who are risking infection will want to read about ivy-poisoning, its prevention and cure in James B. McNair's book.

Mr. McNair has set forth facts about poison ivy which may save the vacationist infinite discomfort. He has made identification of the plant easy, has told how to avoid infection, and how best to effect a cure. Contrary to popular opinion, the poison is not carried by the air or the pollen, but is held in the sap, coming to the surface only when the plant is injured. To avoid touching the plant is, therefore, the best preventative, but the poison may reach the susceptible person by way of intermediate agents.

As a complete preventative, McNair advises washing the exposed surface of the body with a solution of 5 per cent iron chloride in 50 per cent alcohol and water. This application will render harmless any ivy poison it touches; prevents the action of the poison before it enters the skin, and stops its spread from one part of the body to another. This substance was known to alchemists hundreds of years ago. It was used as a remedy for poison ivy in 1885, and by 1895 was known to act chemically on the poison.

This substance will work no miracle; its application will not immediately heal ivy-blistered skin. The injury caused by the poison is similar to a burn, and will not heal in a day. As the Great War has shown, the best remedy for burns is paraffin, and it is this substance that McNair has found most effective in stopping the pain and assisting in the repair of ivy-blistered skin. Vacationists who wish to avoid having their vacation ruined by the ivy plant will do well to include some iron-chloride mixture and a few paraffin candles in their kits. But before they start, let them read "Rhus Dermatitis!"

FOR SALE—General practice in village of 1,000. Sixty-five miles south of Twin Cities. Large country territory. Also care for three other country villages. Wonderful opportunity to make good. Address B100, care MINNESOTA MEDICINE.

MINNEAPOLIS OFFICE SPACE TO SUBLET — Very desirable office space at 323 La Salle Bldg., Minneapolis, to be sublet by Drs. Willson, Cabot and Wohlrabe. For information call at office or telephone Main 3220.

WANTED—Physician for an excellent Minnesota location, where money can be made right from the start. Nothing to buy. Address B95, care MINNESOTA MEDICINE.

PHYSICIAN'S OFFICE FOR RENT—Hamm Bldg., St. Paul. Centrally located. Dental office in connection, with furnished reception room. Call Cedar 2460 or address C1, care MINNESOTA MEDICINE.

CLINICAL FEATURES OF CORONARY SCLEROSIS*

FREDRICK A. WILLIUS, M.D.
Section on Clinical Cardiology
Mayo Clinic
Rochester, Minnesota

The correlation of clinical data and necropsy findings in cases of coronary sclerosis permits a definite classification of clinical types. The following data are based on eighty-six necropsies disclosing coronary sclerosis.

GROUP 1. TYPICAL ANGINA PECTORIS

Typical angina pectoris occurred in 24 per cent of the cases. This type includes cases in which attacks of retrosternal pain are induced by cardiac overload and in which variable radiations of pain occur. There may be a sense of impending death associated with the attacks. The seizures are usually of short duration, are invariably relieved by immobility, and by the administration of nitrites. The average coronary sclerosis in this group was very marked (3+), and in 66 per cent of the cases some of the vessels had become definitely occluded. In 14 per cent of the cases, myocardial infarction had occurred. Besides coronary sclerosis, 19 per cent of the patients had syphilitic aortitis, and one patient had an aneurysm, about 7 by 9 cm., and saccular in form, just above the orifice of the left coronary, and another patient had a diffuse aneurysm of the arch.

GROUP 2. ATYPICAL ANGINA PECTORIS

By atypical angina pectoris is meant a syndrome consisting of attacks of pain induced by cardiac overload and usually located in the upper abdomen, with a variable radiation of pain, and in other respects resembling the typical syndrome. These symptoms very often lead to confusion with surgical diseases of the abdomen requiring surgical treatment. Atypical angina pectoris occurred in

2 per cent of the cases. In one patient the degree of coronary sclerosis was extremely marked, and one of the coronary orifices was almost completely obliterated by an advanced syphilitic aortitis. One patient had a moderate degree (2) of coronary sclerosis, with slight atheroma, and distinct calcareous changes at the root of the aorta and the aortic valves.

GROUP 3. PROGRESSIVE MYOCARDIAL FAILURE

Cases in this group, in which painful attacks are absent, are characterized by symptoms of a failing myocardium. This syndrome occurs in about 26 per cent of the cases. The symptoms may vary from dyspnea on effort to the typical clinical picture of heart failure as evidenced by orthopnea, cough, cyanosis and anasarca. A small number of these patients have paroxysmal attacks of dyspnea, often independent of cardiac overload, and their symptoms conform to the clinical entity called "angina pectoris sine dolore" by the old clinicians. The average coronary sclerosis in this group was only moderate (2+), and occlusion occurred in only 23 per cent of the cases. Myocardial infarction was present in 14 per cent of the cases.

GROUP 4. ANGINA PECTORIS AND PROGRESSIVE MYOCARDIAL FAILURE

In the cases in this group the symptoms of a failing myocardium are associated with typical attacks of angina pectoris. The clinical differences between Groups 1 and 3 are so striking as to make the creation of this fourth group desirable. This syndrome occurred in 8 per cent of the cases. The average degree of coronary sclerosis in this group was marked (3+), and the incidence of occlusion quite high (57 per cent). Infarction of the myocardium occurred in only 14 per cent of the cases.

GROUP 5. OCCULT CORONARY SCLEROSIS

It is very significant that, in 40 per cent of the cases coming to necropsy, the diagnosis of coronary sclerosis was not made by the clinician. In carefully reviewing the records of the patients, it was found that there was insufficient subjective or objective evidence of heart disease to establish the diagnosis with the usual clinical methods of

*Read before the Southern Minnesota Medical Association, Mankato, May, 1924.

examination. A large majority of the patients were old, in that period of life when degenerative processes are at work. It is important to appreciate the fact that a considerable degree of coronary sclerosis may exist with relatively little cardiac insufficiency or evidence of organic cardiac disease. It is, therefore, always well to consider the likelihood of occult coronary sclerosis when appraising the physical fitness or the surgical fitness of patients in middle or later life. The greater application of special lines of cardiac investigation, such as electrocardiography, is desirable, as very often graphic signs are detected which center attention at once on the coronary arteries. The average degree of coronary sclerosis was moderate (2) and occlusion occurred in only 15 per cent of the patients, the lowest incidence in any group. There was no instance of coronary embolism. The pathologic findings are significant in that the degree of sclerosis is only moderate, and the tendency for a patent sclerosis exists.

ASSOCIATED PATHOLOGIC FINDINGS

The thoracic aorta was diseased in 99 per cent of the eighty-six cases; there were sclerosis, atheroma and ulceration in 90 per cent, and syphilis in 9 per cent. The abdominal aorta was sclerotic, atheromatous and ulcerated in 21 per cent of the cases, and in one case a non-syphilitic aneurysm was present.

The cardiac valves were involved by sclerosis, fibrosis or atheroma in 50 per cent of the cases, while in one case an acute vegetative tricuspid endocarditis was present. The aortic valves were affected with greatest frequency, and the mitral and tricuspid valves in order of frequency.

There was evidence of myocardial degeneration in all cases; this consisted of fibrosis, fatty degeneration, cloudy swelling, segmentation and fragmentation of the muscle bundles. In two cases there were areas of necrosis, and in one case, brown atrophy. Infarction of the myocardium occurred in 8 per cent of the cases.

Disease of the pericardium was found in 9 per cent of the cases, and consisted of chronic adherent pericarditis in four, chronic fibrinous pericarditis in two, terminal fibrinous pericarditis in one case, and obliterating tuberculous pericarditis in one.

Arteriosclerosis of the peripheral vessels was evident in 70 per cent of the cases, and arteriosclerosis of the kidneys in 37 per cent. Cerebral arteriosclerosis was found in thirteen of the fifteen brains examined.

Nephritis was present in varying degrees in 53 per cent of the cases.

It is interesting to note that there was disease of the gallbladder in 26 per cent of the cases; this increases the difficulty many times in differentiating the atypical type of angina pectoris from disease of the gallbladder. The co-existence of disease of the gallbladder and angina pectoris must always be considered when there is a question of surgical intervention.

The association of hypertension and coronary sclerosis is generally considered a very unfavorable combination, especially in patients subject to attacks of angina pectoris. The added load cast on the heart by a well advanced hypertension is considerable, and obviously enhances fatigue and degenerative changes of the myocardium. The myocardium in the majority of cases of coronary sclerosis is already the seat of disturbances in nutrition, and any added insult undoubtedly increases the rate of progression and the degree of structural damage. Hypertension was present in 31 per cent of the cases in this study; in 43 per cent of the cases of typical angina pectoris; in 55 per cent of the cases of progressive myocardial failure; and in 18 per cent of the cases of occult coronary sclerosis. The average systolic pressure in the whole group was 183, the average diastolic pressure 111, and the average pulse pressure 72.

The frequency of the association of obesity and degenerative cardiovascular disease prompted particular inquiry into this relationship, with special reference to sclerosis of the coronary arteries. The height and weight of forty-nine patients in this study were available, and 29 per cent were distinctly obese.

MODE OF DEATH WITH CORONARY SCLEROSIS

Sudden Death.—The frequency of sudden death in cases of coronary sclerosis has been appreciated for many years. Of the cases reported here, sudden death occurred in 37 per cent. The highest incidence occurred in patients with typical angina pectoris, 33 per cent of the patients dying suddenly. In order of frequency, the other clinical types of coronary sclerosis attended by sudden death were: occult coronary sclerosis, 21 per cent; angina pectoris with progressive myocardial failure, 19 per cent; progressive myocardial failure, 17 per cent, and atypical angina pectoris, 6 per cent. Sudden death in angina pectoris is not unexpected. The

rather high incidence of sudden death in both the progressive myocardial failure type and in the occult type of coronary sclerosis implies the necessity for more accurate diagnosis, and for the identification of the pathologic processes underlying myocardial degeneration.

The average degree of coronary sclerosis was pronounced (3+) and occlusion was evident in 56 per cent of the patients. Seventy-one per cent of the patients with myocardial infarction died suddenly.

Gradual cardiac failure.—Death was the result of gradual cardiac failure in 15 per cent of the cases. The incidence according to clinical types was as follows: typical angina pectoris, 38 per cent; progressive myocardial failure, 38 per cent; occult coronary sclerosis, 14 per cent, and angina pectoris and progressive myocardial failure, 8 per cent.

The average degree of coronary sclerosis in patients who died from gradual cardiac failure was quite advanced (Grade 3), but there was less tendency to occlusion (38 per cent). Myocardial infarction occurred in only 8 per cent of the cases.

Death from other causes.—Causes other than heart disease were responsible for death in 48 per cent of the cases. This group included patients suffering from diseases such as chronic nephritis, cerebral hemorrhage, diabetes mellitus, carcinoma of the stomach, carcinoma of the pancreas, carcinoma of the prostate, and cirrhosis of the liver. The incidence of clinical types in this group is significant, in that 68 per cent of the cases were of the occult coronary sclerosis type. This indicates that the patient's attention is chiefly directed to his major complaint, and that in the physical examination the appraisal of the cardiovascular system is probably not sufficiently thorough. There unquestionably are instances in which the identification of occult coronary sclerosis is impossible, yet every effort should be made to make this group minimal. The other clinical types, in which death resulted from causes other than heart disease, were

the progressive myocardial failure type, 27 per cent, and typical angina pectoris, 5 per cent.

ELECTROCARDIOGRAPHY IN CORONARY SCLEROSIS

The electrocardiogram is of great aid in the diagnosis of coronary sclerosis. The high incidence of certain graphic abnormalities in proved cases of coronary sclerosis makes this a valuable clinical adjunct, and the more routine application of electrocardiography in cases in which coronary sclerosis is likely to exist will aid materially in the identification of the occult or unrecognized type. The most frequent graphic abnormality present is the inversion or negativity of the ventricular T wave in certain isolated or combined derivations.^{2, 5}

In this study, of the patients receiving electrocardiographic examination, 68 per cent showed significant graphic abnormalities. In a previous study³ of 155 cases of angina pectoris, significant electrocardiographic changes were found in 51 per cent.¹ There is little doubt that the use of the electrocardiograph in conjunction with careful clinical study is of great help in identifying obscure cases of coronary disease.

Salvarols and Insulols.—Salvarols are stated by the Drug Products Company to be rectal suppositories containing arsphenamin. The lack of evidence for the value of the rectal administration of arsphenamin was the subject of a report of the Council on Pharmacy and Chemistry in 1920, and the Council's conclusions have been fully confirmed. Insulols are stated by the Drug Products Company to be suppositories made "with carefully selected desiccated pan-

creas including the islands of Langerhans containing insulin in a safe and reliable form." The rectal administration of insulin has been tried, but without success. No preparation of the Drug Products Company has been admitted to New and Non-official Remedies. On the other hand, the Council on Pharmacy and Chemistry has reported unfavorably on the firm's "Pulvoids Calcylates," "Pulvoids Calcylates Compound" and "Pulvoids Natrium Compound" (*Jour. A. M. A.*, July 26, 1924, p. 289).

RADIUM IN BENIGN CONDITIONS OF THE NOSE AND THROAT *

LAURA A. LANE, M.D., F.A.C.S.
Minneapolis

In presenting the subject of radium in benign conditions of the nose and throat I am not unmindful of the fact that considerable controversy and confusion as to the value of radium exists in the minds of a large number of our profession. A few preliminary words about radium and the why of this confusion may not be out of place.

A little over twenty-four years have passed since radium was first introduced as a therapeutic measure. A great deal has been written about radium, especially of its use in malignancy and the results in the latter have not been as satisfactory as at first hoped. It is gratifying to find that radium is proving eminently satisfactory in many benign lesions and that it has a decided field of usefulness in rhinolaryngology.

For over three years the writer has been engaged in making a review of the literature of the last twenty years as it relates to the use of radium in the field of oto-rhino-laryngology and ophthalmology, and has also studied considerable other radium literature with reference to the properties of radium, methods of its application, its uses and the results both in malign and benign lesions.

The work and results of many experienced radium workers have been observed from time to time and personal work with radium for more than two years together with the data gathered from the above studies convinces the essayist that much of this misunderstanding has resulted from the following facts.

At first some of the earlier work was done with preparations of doubtful strength. For example, one eminent authority, who has done considerable radium work about the head, after using radium for nearly ten years with more or less unsatisfactory results, found his preparation contained only a small amount of real radium and not sufficient for malignant work.

Second, knowledge of the properties of the different rays, of screening and of the best methods of using radium, until quite recently, was often hazy in the minds of some of its users. One states

that the gamma rays from a 50 mg. quantity have little power of penetration. We now know that the gamma rays in general are many times (some estimate one hundred times) more penetrating than the other rays.

Third and perhaps the most unfortunate is the fact that radium has been used and exploited by some who were ill prepared to use it scientifically and successfully. Consequently it has been tried in many conditions totally unsuited to its use as well as being improperly used. What else but failure and disappointment could result under such circumstances?

Thanks to the painstaking efforts and observations of many experienced radium workers, this form of therapy is to-day on a securer foundation than ever before. Pardon me if these opening remarks have seemed a trifle tiresome but prejudice and pessimism instead of an open mind, especially among those who have had no personal experience in using radium, is all too common and lead us nowhere.

Turning to the field of rhinolaryngology we find radium of benefit in the following benign conditions and diseases.

GROUP I

BENIGN LESIONS OF THE NOSE IN WHICH RADIUM HAS PROVED OF VALUE

1. Angioma.
2. Chronic rhinitis.
3. Fibroma—nasopharyngeal.
4. Hay fever.
5. Hyperplastic conditions.
6. Polypi.
7. Postoperative ethmoid and sphenoid conditions.
8. Rhinophyma.
9. Rhinoscleroma.
10. Syphilitic lesions.

Radium is a specific in angioma, whether of the nose, throat or other portions of the body. Crowe¹ considers angioma of the nose more frequent than the textbooks would have us believe. He says the results with radium are very good but may be a little slow.

Aitkins² reports favorable results in several cases of chronic rhinitis, particularly an intractable case with infection of the vibrissæ and upper lip as well as the nasal mucosa. These are difficult cases to treat and we welcome a remedy which gives

*Read before the Southern Minnesota Medical Association, Mankato, May, 1924.

prompt relief. Several have had success in treating naso-pharyngeal fibromas. These growths are unsatisfactory to treat surgically on account of hemorrhage and recurrence. Radium fails occasionally to remove completely very large fibromas. Park³ reports success with the use of emanation in hay fever. To get the best results radium must be used early before the hay fever season begins.

Shea⁴ had found radium of considerable value in treating postoperative ethmoid and sphenoid lesions and in hyperplastic conditions. It stimulates healing and prevents troublesome granulations. The essayist has confirmed Shea's experience and has yet to find any remedy which so effectively and speedily relieves the severe headaches and neuralgias which accompany sphenoid disease. Thirty to 50 mg., well screened, are used from two to three hours once in seven to fourteen days as indicated.

Polypi have yielded excellent results with radium. Much credit is due to Lyons⁵ for his work in this field. While radium does not cure every case of polyps, it produces a fibrosis in the myxomatous type so that surgical procedures are rendered more effective. Lyons states, "Definite operative cures occur more often with radium than without." While the writer's experience is not large, four cases have remained free from return and troublesome symptoms for more than a year, and several other cases of a shorter duration appear to have been greatly improved. Sluder⁶ has recently reported benefit from the use of radium in nasal polyps. Fifty mg., using a silver, gold or platinum screen with rubber, may be left in situ for two to three hours at intervals of once a week for three to four sittings and repeated if needed.

Several reports of the treatment of rhinophyma and rhinoscleroma were found. Syphilitic lesions of the nose which failed to respond to anti-syphilitic treatment cleared with radium. The rhinologist is frequently consulted for certain skin lesions of the nose such as nevi, lupus erythematosus, eczema, ulcers, and occasionally blastomycosis lesions of the lids extending onto the nose. In all these conditions radium is of decided value.

GROUP II

BENIGN CONDITIONS OF THE THROAT IN WHICH RADIUM HAS PROVED OF VALUE

1. Angioma of larynx.
2. Angioma-like masses at base of tongue.

3. Benign papilloma of larynx.
4. Hyperplastic conditions of the larynx.
5. Chronic pharyngitis.
6. Follicular tonsillitis.
7. Hypertrophied tonsils.
8. Hypertrophied lingual tonsils.
9. Tuberculous tonsils.
10. Vincent's angina.

OTHER CONDITIONS OF THE HEAD AND NECK OCCASIONALLY ASSOCIATED WITH DISEASE OF THE NOSE AND THROAT

1. Tuberculous glands.
2. Tuberculous sinuses.
3. Pituitary lesions.
4. Thrush.
5. Actinomycosis.
6. Leukoplakia.

Angioma of the larynx is rare. New⁷ reports three cases where radium was of benefit. The large masses of angioma-like vessels or varices found at the base of the tongue may be entirely and easily removed by the application of radium.

Radium is a specific in papilloma of the larynx. American laryngology owes much to Abbe⁸ who discovered that radium would permanently cure papillomata. Many reports of brilliant results are found in the literature, the one of New⁹ being the largest and most complete. In very extensive papillomas a tracheotomy is required and the radium is inserted through this opening into the papilloma. External radiation may be combined with the intralaryngeal application when the papilloma interferes with a laryngoscopy.

Radiation must be evenly distributed. Doses of 25 mg. in a silver or platinum capsule unfiltered except for rubber have been used for one and a half hours with good results. This dose is repeated once a month for two or three times. Larger doses of 50 to 100 mc. of emanation with a silver screen and rubber used for twenty to thirty minutes and repeated in six weeks for two or three times have been very effectual.

Hyperplastic conditions including tuberculosis of the larynx have responded well to radium therapy. Freudenthal¹⁰ and others have reported good results in tuberculosis of the larynx; the former reports a series of ten cases using a 10 mg. aluminum capsule. The writer has used a small 15 mg. platinum needle unscreened except for rubber for half an hour to one hour, repeating the dose once a month

for five doses in a case of hyperplasia and edema of the larynx. Excellent results were obtained. (Case 1.)

Chronic pharyngitis with large dilated vessels and lymphoid masses will respond to radium. Crowe¹ of Johns Hopkins, in a recent article, states, "We believe it would be a wise precaution to treat with radium every adult patient that has a localized hypertrophy of the lymphoid tissue limited to the nasopharynx, rather than to remove it with the curet."

By far the larger number of cases of the nose and throat treated with radium are those of the tonsil. Several report success in treating tuberculous tonsils, the lung process being delayed and the general condition improved. Large lingual tonsils are reduced easily and much more satisfactorily than by surgery. Leukoplakia of the tonsil and mouth has been cured by radium.

More than 500 cases of hypertrophied and pathologic tonsils treated with radium were compiled from the literature. In addition there were several writers who did not report the exact number of cases they had treated, but simply stated they had used radium successfully many times. In 200 cases, the work of two authors, only eight cases or 4 per cent were not reduced or unsatisfactory.

Robinson¹¹ reports the largest series, 156 cases, with but five unsatisfactory results. Neuritis of long standing was cured. Marked remission of symptoms and improvement in chronic catarrhal otitis media were noted.

Williams,¹² who is highly trained, experienced and a conservative worker, reports a series of 101 cases, ranging in age from five to sixty years. He found recurrence of tonsillitis prevented, enlarged glands reduced, arthritis improved and the method satisfactory in 93 per cent of his cases (followed two years).

Acutely inflamed tonsils seem to respond quicker to radium. This has been observed by several and a case to illustrate this point is given (Case 2). There are a few other conditions about the head and neck which the rhino-laryngologist occasionally meets with where radium has proved of value. Tuberculous glands often associated with tuberculous tonsils, likewise cervical adenitis associated with pathologic tonsils, respond well in 90 per cent of the cases. The essayist has found radium of use in closing a stubborn tuberculous sinus of the neck.

Pituitary lesions associated with sphenoid disease, hyperplasia and other conditions have been found to be benefited by radium combined with the roentgen ray. Actinomycosis of the tonsil and glands has been successfully treated with radium.

CONSIDERATIONS IN THE USE OF RADIUM IN TREATING PATHOLOGIC TONSILS

The use of radium in producing an atrophy of the tonsil is founded on sound biologic principles. The tonsil is largely composed of lymphoid tissue. It has been known for years that this type of tissue is very susceptible to the action of radium and the roentgen ray. That radium produces an atrophy has been shown by Wells.¹³ Two years ago the essayist removed a piece of tonsil tissue from a patient who had had three 25 mg. doses of radium and found microscopic evidences of definite areas of atrophy and fibrosis in many of the follicles.

It has been seen from the reports of those who have had considerable experience with this form of therapy that symptoms are relieved, the treatments are painless and without untoward effect when properly given. Complete atrophy can be obtained if the treatment is sufficiently carried out. This form of therapy is suited to the treatment of simple hypertrophied tonsils and adenoids of children, with patients suffering from heart disease, chorea, hemophilia, tuberculosis and other debilitating diseases where operation is contraindicated.

The writer considers that radium is contraindicated in patients with the following tonsil conditions and operation is indicated:

1. History of repeated attacks of tonsillitis and peritonsillar abscess.
2. Small, firm, sclerosed, submerged tonsils with history of frequent sore throats.
3. Badly infected tonsils causing acute poly-arthritis, acute kidney, certain eye lesions and other definite evidences of infection.
4. Cases of rapidly increasing deafness and ear infection clearly due to diseased tonsils and adenoids.

REPORT OF TONSIL AND OTHER CASES

Fifty patients ranging in age from four to sixty-three years are herewith reported. The majority have been observed from one and a half to over two years; no case is reported which has not been followed at least one year. All but five were re-examined or communicated with within the past thirty days.

RESULTS ONE TO TWO OR MORE YEARS AFTER

TREATMENT

	Number	No Return of Symp- toms	Im- proved	Unsatis- factory
Total number	50	33	14	3
Untraced	1	1
Hypertrophied type	44	27
Small type	6	6
Tonsillitis	19	18	..	1
Sore throat	22	18	3	1
Frequent colds	21	18	3	..
Enlarged glands	20	18	2	..
Acute and chronic ear con- ditions	14	12	2	..
Arthritis	8	7	1	..
Chorea	1	1
Nervous	4	3	1	..
Radium used with x-ray of glands	6	5	1	..

Many patients have gained in weight. Improvement in breathing and greater freedom from frequent colds have been noted. Glandular enlargements have been reduced. Six patients with extensive glandular involvement and many follicles on the pharynx were treated with the roentgen ray in addition to the radium. One patient has had a tonsillectomy. This patient had very large tonsils, several abscessed teeth, and took but one treatment. The tonsils were considerably reduced and the tonsillectomy was not done for many months after the treatment when the teeth gave trouble.

A severe case of chorea (Case 3) responded remarkably well. Several patients with acute follicular tonsillitis obtained almost immediate relief. A patient with a Vincent's angina of two weeks' duration which had not responded to previous treatment was entirely healed on the fifth day after a 40 mg. dose.

Considerable care has been used in selecting patients for radium therapy. Special attention has been paid to the diet and removing other foci of infection. Of the fourteen cases classed as improved six consider their condition satisfactory. Nine of the fourteen have had only one treatment to each tonsil, which was not at the time deemed sufficient; likewise several of those having no return of symptoms. In four of the improved and two of the unsatisfactory, diet and home environment are still very faulty. Many show throats cleaner, smoother and freer from remnants and scarring than is seen oftentimes following tonsillectomy.

In 1922 the essayist presented a report¹⁴ of a somewhat similar group of patients treated with

the roentgen ray. A review of these cases has been made. Not nearly so many could be traced or re-examined as in this study. The results on the whole have been less satisfactory than with the radium. Radium has the advantage of being placed where it is needed, namely, within the tonsil. It causes a much more uniform reduction and without any unpleasant symptoms. No burns or other untoward effects have been noted in the radium therapy of any nose or throat patient.

Case 1.—Edema and hyperplasia of larynx. A. M., a man, aged 27, was seen October 13, 1922. He complained of hoarseness and dyspnea of three years' duration; also of an ozena of many years' duration. He had no pain. He gave a history of having been under observation for a tuberculosis of the lungs for several years, but at that time it was inactive.

Examination: The patient is a well developed slightly obese man. He has an extensive ozena of the left nostril with a lesser involvement of the right one. Some dental caries is present; also a chronic pharyngitis. Some tonsil tissue is left in each fossa. There is no glandular involvement. Examination of the larynx shows the arytenoid tissues much thickened and edematous. The vocal cords are not visible, being hidden by the enlarged ventricular bands. No evidence of ulceration is present. The epiglottis is not involved.

The Wassermann is negative. The basal metabolism is a minus 7 per cent. Report of the x-ray and chest examination shows an apparently healed lesion. The heart and other findings are negative.

Treatment: A small 15 mg. platinum needle, unscreened except with two thicknesses of rubber, held in place by a silver wire, was introduced over the arytenoid area for a half hour. Its position was frequently changed. No reaction followed the application and one month later the dose was repeated for one hour. Treatment was prescribed for the ozena. As a result the hyperplasia became markedly decreased, the vocal cords were easily seen, and the edema entirely disappeared. The hoarseness and dyspnea were greatly relieved. The patient's condition has remained good to date.

Case 2.—Acute follicular tonsillitis. Mrs. S. D., aged 38, was first seen in January, 1914. The previous week she had had a severe attack of tonsillitis. Examination showed a large left inflamed bulging tonsil with a peritonsillar abscess. This was drained and treated. On the eighth day, when about recovered, she had a spontaneous hemorrhage from the center of the left tonsil. This bleeding persisted at intervals for a period of three days in spite of every effort to control it.

In 1915 she had another attack with evidences of focal infection from the tonsils. Operation was advised after recovery. In 1916 she was seen again with a peritonsillar involvement. A short time after she moved away and was not seen again until January, 1922. She gave a history of several attacks of tonsillitis since last seen. There was present on this date a severe follicular tonsillitis with tem-

perature of 102. A 10 mg. platinum needle was embedded in the left tonsil for three hours. The other was painted with 25 per cent silver nitrate. The following morning the left tonsil was very much cleaner and the swelling and inflammation decidedly less than on the right side. The temperature was 99. A similar dose was then used on the right tonsil. Improvement was rapid. The patient reported relief from pain, from difficulty in swallowing and less aching than with any other form of treatment she had ever had during an acute attack of tonsillitis.

An additional dose of 50 mg. was used a few weeks later in each tonsil. Up to May, 1924, this patient has not had a sore throat or cold since the first treatment. She has gained considerably in weight, and her rheumatism and tired feeling have entirely disappeared. The tonsils before treatment extended two-thirds the distance to the uvula. They now are well within the pillar line, the surfaces are clean and no pus can be expressed. Another treatment was advised in order to bring about the entire disappearance of the tonsillar tissue. The patient, however, considers this unnecessary while her present condition is so satisfactory.

Case 3.—Chorea. E. P., aged 6. She had been excluded from school in 1922 on account of a severe chorea. She had had an attack of tonsillitis in December, 1922. Examination showed some cervical enlargement; the tonsils extended more than half way to the uvula, were inflamed and ragged. She was very nervous and had a typical chorea. This child was undernourished and finicky about eating. She weighed fifty pounds. She had had many earaches but no suppuration.

On January 3, 1923, the right tonsil was embedded with a 15 mg. needle for three hours. She was put on a rigid diet containing plenty of vitamins and more rest was prescribed. On January 16 the left tonsil was treated in a similar manner. On January 27 she was better and on February 10 she was able to return to school for short sessions. She had gained several pounds and her chorea was not noticeable unless she became overtired.

In March both tonsils were again treated by the same method. Her heart action was better and her general condition much improved. On April 18 her chorea was entirely gone, the tonsils were scarcely visible and she was in school full time. May 1, 1924, she had had no colds or sore throat since the treatments began. There had been no earache, and the nervousness and chorea had entirely disappeared. There was no cervical enlargement. She had gained eleven pounds and was in excellent condition. The tonsil fossæ were clean.

GENERAL CONSIDERATIONS IN THE USE OF RADIUM IN THE NOSE AND THROAT

A thorough knowledge of radium, of proper dosage and screening is absolutely essential to its successful use. Radiation must be evenly distributed to get the best results. Great harm can be done with radium if not properly applied. No untoward effects in benign lesions have been noted when radium was carefully used.

Extreme care must be taken in selecting cases, particularly in tonsil work, so that discredit may not be given this form of therapy. The tendency seems to be to use filtered rays with smaller doses and more frequent application, thereby securing better results.

Mottram¹⁵ and others have shown that radium if long continued or used in large doses produces a condition identically similar to an avitaminosis. Therefore attention must be paid to the physical condition and diet of patients undergoing radium therapy.

Judgment and experience are necessary in using radium. It is no longer an entirely experimental agent and it offers valuable possibilities in experienced hands in bringing relief in many troublesome conditions of the nose and throat. Dosage can now be estimated almost as accurately as with any ordinary drug. Painstaking observations are essential in creating a wider field of usefulness in radium therapy in rhinolaryngology.

ADVANTAGES OF RADIUM

Radium possesses many advantages over the roentgen ray in the treatment of benign conditions of the nose and throat. It has the advantage of being applied directly to the lesion without harm to the surrounding normal tissues.

Freedom from pain, less loss of time from work, and avoidance of scarring characterize the use of radium in the majority of nose and throat cases. Uniformly good results without danger and accident incident to surgery and anesthetics about the head make radium a highly desirable form of therapy in many lesions.

SUMMARY

1. Radium is of distinct value in many benign lesions of the nose and throat.
2. It is a specific in papilloma of the larynx and in angiomas of the nose and throat. It gives promise of being of considerable value in the treatment of nasal polyps.
3. Lymphoid hyperplasias of the throat and nose yield quickly to radium since lymphoid tissue is very radio-sensitive.
4. Radium is of value in treating pathologic tonsils of patients suffering with heart disease, chorea, hemophilia, tuberculosis, other debilitating conditions and in the simple hypertrophied tonsils of children.
5. Radium offers less scarring, less loss of time

from work and more slightly results than surgery in many conditions about the head.

6. Every unnecessary operation does some harm to medical science.

7. A thorough knowledge of radium, its effects, and methods of application is essential to its successful use in nose and throat work.

8. Much remains to be learned about the type of lesions best suited to radium therapy. Pains-taking observation of cases and more uniform methods of reporting technic and results is highly to be desired in the field of rhino-laryngology.

DISCUSSION

DR. B. E. HEMPSTEAD, Rochester: Dr. Lane has given us a paper which I consider to be very timely. For a long time, radium has been considered of use in only malignant conditions. Recent work of many men has proven that its greatest usefulness is in some benign conditions. In the Clinic, it has been used in angiomas, nasopharyngeal fibromas, rhinoscleromas, papillomas of the larynx, leukoplasias, actinomycosis, thrush, and nasal polyps. The very extensive experience of New has shown that it is specific in angiomas, papillomas of the larynx, and nasopharyngeal fibromas. He also advised the use in actinomycosis, but merely for the purpose of breaking down the mass. We have not used it in acute infections nor in tonsil work unless the case is a malignant one.

A word of warning must be given. Radium should be used only by competent people, since burns and sloughs may occur from its improper use. It may be used either in the form of the salt, the emanations in tubes, or the emanations in seeds. A thorough knowledge of each is necessary.

HYPERTENSION: AN INDEX TO THE TOXEMIA OF PREGNANCY*

ROBERT D. MUSSEY, M.D.

and

LAURENCE M. RANDALL, M.D.

Section on Obstetrics, Mayo Clinic
Rochester, Minnesota

The toxemia occurring in the later months of pregnancy may be ultimately manifested by eclampsia, which claims for its victims 25 per cent of the women who die yearly as a result of childbirth. Vogeler, in 1907, directed attention to the importance of watching closely the pregnant woman with increasing hypertension for symptoms of impending eclampsia. Since his observations, a great deal of attention has been paid to blood-pressure readings during pregnancy, and much has been written on hypertension in the toxemias of pregnancy. Adair, in 1923, reviewed the literature and cited examples of the various types. Routine interval blood pressure readings, beginning early in pregnancy, have come to be regarded by many observers as of equal, if not of greater, importance than routine urinalyses for albumin.

Routine monthly blood-pressure readings give one the impression that during the early months of pregnancy the blood pressure of many patients is subnormal (below 120), and that there frequently is a gradual rise during pregnancy. In this review of 523 cases of pregnancy, a pressure of 140 mm. of mercury or more was considered as definite evidence of hypertension. In most cases, readings were made over a period of several months, usually from the third month on. In all cases, the urine was tested for albumin. One hundred four of the 523 patients had at some time during their pregnancy, a systolic pressure of 140 or more (Figs. 1 to 4).

Figure 1 shows the curve of the incidence of pregnancy according to the age of patients; over 55 per cent occurred between the ages of twenty-five and thirty-five years. This is given for contrast with the curve showing that in this decade the percentage of patients having hypertension was lowest.

Figure 2 shows the number of patients having hypertension, according to their parity. It is of interest that more than 27 per cent of patients in

*Read before the Southern Minnesota Medical Association, Mankato, May, 1924.

the Para I group had hypertension, the percentage dropping steadily to about 5 in the Para V group, and rising rather abruptly in the Para VI (and over) group. This abrupt rise is apparently due

associated with toxemia, (2) hypertension resulting from chronic nephritis, and (3) the so-called essential hypertension.

Under this classification hypertension is of more significance in some cases than in others. In each case it is necessary to determine the cause of the hypertension relatively early. The non-pregnant woman rarely has essential hypertension before the fourth decade of life. In the pregnant woman it is not accompanied by an appreciable amount of albumin in the urine, nor by the usual symptoms of toxemia; that is, edema, headaches, dizziness and abdominal pain.

It may be difficult to differentiate chronic nephritis. In a mild case in the early months of pregnancy the woman may have normal blood pressure and no urinary abnormality, aside possibly from a low specific gravity which points toward pre-existing nephritis. Occasionally there will be a history or record of acute nephritis, or of symptoms of toxemia during a previous pregnancy. Study of the ocular fundi may reveal evidence of old trouble.

The differential diagnosis may only be made later in pregnancy when, besides the toxic symptoms, evidence is found of lowered phenolsulphonphthalein output in the urine, and retention of

Fig. 1. The dash line represents the incidence (per cent) of pregnancy according to age, and the heavy line, patients (per cent) according to age, with systolic blood pressure over 140.

Fig. 2. Percentage of patients with systolic blood pressure over 140 according to parity.

to the increasing incidence of chronic vascular disease in the older patients.

In Figure 3 is shown the finding with regard to albumin in the urine, which may or may not be of importance. A faint trace, which is of no significance, was found in 123 patients without hypertension. A patient may have a marked amount of albumin in the urine without any rise in blood pressure or other evidence of toxemia. This may be due to pyelitis and, more rarely, to the nephrosis of pregnancy. More or less albumin was found in 50 per cent of the entire group; only 50 per cent of patients with hypertension had more than a faint trace of albumin. This bears out Litzenberg's findings in 1917.

De Snoo, in 1922, divided the hypertension of pregnancy into three groups: (1) hypertension

Fig. 3. Relation of albumin in urine to hypertension. Albumin 1, heavy line; albumin 2, dash line; albumin 3 and 4, dotted line.

urea in the blood. One of the peculiar phases of the toxemia of pregnancy is the lack of evidence of renal deficiency aside from chloride retention. In this it closely resembles "trench nephritis" (acute glomerular nephritis). In fact, Keith asserts that the symptoms and findings of so-called eclampsia may be identical with the convulsive type of trench nephritis. The differential diagnosis is most important on account of treatment and prognosis. Although essential hypertension must be carefully watched it does not carry a bad prognosis. The prognosis of toxemia is good if the early symptoms are relieved and eclampsia is avoided, but the prognosis in cases of chronic nephritis is usually poor.

Fig. 4. Heavy line represents patients below thirty years of age, and the dash line patients above thirty years of age, showing the incidence of various grades of hypertension (per cent).

Of the 104 patients with hypertension, sixty-one had varying grades of toxemia, ten had essential hypertension, and ten had chronic nephritis. Of the remaining twenty-three, many of whom had a pressure between 140 and 150, the data were insufficient for diagnosis. Most of these were examined for the first time shortly before or during labor, and had only one blood-pressure reading.

A review of the eighty-one cases of hypertension in which diagnosis was possible tends to bear out the hypertension curve according to age and parity, as shown in Figures 1 and 2. Of the patients with hypertension below the age of thirty, 72 per cent had toxemia, while 54 per cent of those with hyper-

tension over the age of thirty, had toxemia; 67 per cent of the patients with toxemia were Para I, while only about 40 per cent of the entire group were Para I. It is not uncommon to carry through subsequent normal pregnancies a patient who, in her first pregnancy, had hypertension with definite evidence of toxemia. Figure 4 shows that patients over thirty years of age have the more severe grades of hypertension, due mainly to the higher incidence of chronic vascular disease in the older woman.

CONCLUSIONS

1. Increasing hypertension during the course of pregnancy at any age points toward the onset of toxic symptoms.
2. Hypertension, especially in the woman under thirty years of age, is a better index of early toxemia than is albuminuria.
3. Toxemia of the later months of pregnancy is most common in primiparous women.
4. The evidence that more than 25 per cent of primiparous women have a blood pressure over 140, and that this hypertension is a fair index of the onset of toxemia, emphasizes the importance of blood-pressure readings at regular intervals as a routine of prenatal care.

DISCUSSION

DR. W. H. CONdit, Minneapolis: Dr. Mussey's excellent study of his series of five hundred cases of pregnancy, relative to the frequency of toxemia, presented to us today, is of unusual interest and demonstrates, as do all carefully analyzed statistics, that the curve of incidence of toxemias of pregnancy is upward, in spite of the general improvement shown by the records of our maternity hospitals.

I was pleased to see Dr. Mussey place the danger mark in the hypertension of pregnancy at 140 systolic. In 1914 I presented an essay before the Cook County Medical Society in Chicago, entitled, "Some Medical and Surgical Problems of Prophylaxis in Eclampsia" and suggested the danger line be placed at 150 systolic pressure.

I also suggested that we discontinue the use of the word

"eclampsia" as it is not a descriptive work. Its derivation is from a Greek word meaning "to flash"—"to shine out brightly"—and is more properly "eclactma" not "eclampsia." Surely there is nothing very bright or shining about the convulsions in toxemia of pregnancy. A better term to use to designate the cases usually called eclampsia is "toxemia with convulsions" or "without convulsions" as the case may be.

The doctor's essay quite forcibly illustrates another debated point in obstetrics, namely that a pregnant woman is in a pathological rather than a changed physiological state. In 1922, ten per cent of the women in this state giving birth to a living child were unattended and unadvised by a licensed physician and forty per cent of these 5,600 women were not even attended by a midwife or nurse. This condition surely demonstrates the need of more education of the public to the necessity of some supervision of all patients in the pregnant state. Again, so long as licensed physicians, irrespective of their obstetrical training, continue advising and delivering the pregnant women, we still have work to do in our profession to improve the service before the mortality and morbidity statistics of pregnancy are improved.

I feel that careful, accurate and conscientious study of the blood tension in pregnancy is the best means so far known to our profession for determining the first signs of toxemia and that any patient so studied can be so treated as to be always protected from the dangers attending toxemias of pregnancy.

SHOULD WE DRINK ICE WATER?

The American habit of drinking ice water is not viewed with alarm by Dr. James Frederick Rogers, writing in the August *Hygeia*, popular health magazine. Dr. Rogers thinks that physicians of a generation or two ago were unduly concerned over the harmful effects of ice water on the stomach.

In some instances harm may be traced to the practice, Dr. Rogers declares, but many persons experience no injurious effects whatever. It does cool the stomach and inhibit digestion but this effect is less than is commonly supposed. Most of the deaths that were formerly attributed to drinking ice water were simply due to heat.

To test out the effects of ice water upon workers exposed to high temperatures, the American Society of Heating and Ventilating Engineers recently carried out some experiments. After being an hour in very hot surroundings, two men drank a quart of ice water in less than fifteen minutes. Cramps did not develop and they experienced no ill effects.

"Most of us can certainly take a moderate amount of at least moderately cold water without harm," concludes Dr. Rogers, "and in hot weather even a larger number can indulge in a reasonable quantity of cold beverages without fear either of deadly effects or even a passing digestive disturbance. In this, as in many other every-day matters connected with our bodily affairs, each man is the best judge of what is good and what is harmful for himself."

THE X-RAY IN OBSTETRICS*

MYER NORMAN MOSS, M.D.

Assistant in Obstetrics and Gynecology,
University of Minnesota Medical School

St. Paul

Roentgenography has already begun to spread its rays of usefulness into the field of obstetrics and, although still in its embryologic stage, gives promise of being as indispensable here in the near future as it now is in all the other branches of medicine and surgery.

During the past eighteen months the writer has been interested in the study of this particular work. At first, roentgenograms were made only in those cases in which some abnormal condition existed or was being suspected. As more of these pictures were taken and closer observations made, it soon became obvious that there was considerable more to be learned than had at first been anticipated. At the present time the x-ray is used in all primiparous patients routinely and in multipara only when some indication presents itself.

Considerable discussion has been created with regard to the effect of the x-ray upon the babe in utero. The consensus of opinion at the present time is that the x-ray can do no harm either early or late in pregnancy. There are some men, however, who contend that repeated exposures during the early months of pregnancy may be sufficient to cause an abortion. There appears to be no opposition to the employment of the x-ray in the last trimester of gestation.

As to the time most suitable for x-raying these patients, it is advisable to wait until the last month of pregnancy; within two to three weeks of the probable date of confinement. The reason for this is threefold: (1) because then the baby is almost completely developed; so that the findings at this time are very apt to persist and to be present when the patient goes into labor; (2) the bony skeleton is more completely ossified, and, therefore, gives a much clearer picture; (3) the cases may be followed from time to time; diagnoses made; findings recorded and then the x-ray used, not as a sole means of diagnosis, but as an aid in checking up these findings and to correct any errors which may have been made.

Of what value is the roentgen-ray in obstetrics?

*Presented before the staff of St. John's Hospital on January 21, 1924.

How may we expect to benefit by its use as an occasional or routine measure in the practice of obstetrics? From my own short experience and from a survey of some of the literature already available upon this subject, I am convinced that by the aid of the *x*-ray one may determine: (1) normal or abnormal relative proportions; (2) the presence of a single or multiple pregnancy; (3) position and presentation; (4) the presence of a monstrosity, e.g., a hydrocephalic, an anencephalic, a double monster, etc.; (5) the presence of a dead baby; (6) the diagnosis of pregnancy.

Relative proportion has been placed at the head of this list because it is one of the most important things to know before labor sets in. An effort is usually made to determine this prenatally, by the aid of the pelvimeter; but while this method is fairly accurate, it does not give all the data necessary for the correct diagnosis of proportion. Too often do patients with apparently normal measurements have prolonged, difficult labors, many times demanding instrumental delivery and occasionally abdominal section. It is therefore important to know not only the size of a pelvis but also the size of the head which must pass through it. An abnormally large head will not pass a pelvic cavity even though the measurements are found normal; while a small head may pass a comparatively small pelvis. The *x*-ray enables us to determine this with the greatest possible degree of accuracy.

The importance of determining whether a mother is carrying more than one baby is self evident. The mother is anxious to know—and should know—whether she is going to have twins in order that she may be prepared for that eventuality, and be less surprised when it is all over. Again, in a patient with a small pelvis, who is carrying twins, the diagnosis of a single large baby may be made; and in order to make her labor less difficult, one may desire to induce labor two to four weeks before the probable date of confinement. In the presence of a single baby, where it is feared that a continuation of the pregnancy for two to four weeks may give rise to disproportion and a subsequent difficult labor, this may be a justifiable procedure, but in the presence of twins which as a rule are already premature, it may mean death to one or both babies.

While it is true that positions and presentations very often change during the last month of pregnancy, still in the vast majority of cases the find-

ings are much the same as when labor sets in. It is important and very convenient to recognize a breech, a face, or an occiput posterior before labor begins, in order that one may be better prepared to meet these more difficult conditions. For the proper determination of position, both antero-posterior and lateral plates are often necessary.

No mistake could be more unfortunate—no embarrassment greater—than the failure to diagnose the presence of a monstrosity, particularly when there is disproportion due to a hydrocephalic baby, and to attempt a version, a difficult forceps, or an abdominal section in such a case; when the correct procedure should be a craniotomy. It is most important that the diagnosis of a monstrosity be made before labor begins, in order to properly meet such a contingency. No method available is a more certain aid in the diagnosis of such cases than the employment of the roentgen-ray.

It occasionally happens that a patient comes to us during the last trimester of pregnancy, for the first time. She had felt life until a few days ago, and is now anxious to know whether her baby is still alive. An examination reveals a very obese type of a patient with a polyhydramnios, making it very difficult to hear the fetal heart. The diagnosis here, as in many other similar cases, may be doubtful, but can be readily cleared up by the aid of an *x*-ray film. If the baby is living, the outline of the fetal skull is regular, but in the presence of a dead baby, because of absorption of some of the cerebral fluid, the bones overlap and the scalp folds, giving the head a very irregular outline.

As to the diagnosis of early pregnancy by the aid of the *x*-ray, one should be able to make a diagnosis by the ordinary methods just as early. It will, however, be of considerable value in helping to differentiate between pregnancy and a tumor, particularly in the presence of a dead baby.

CASE REPORTS

CASE 1.—History.—Mrs. N. P. W., aged 38, first seen during the third month of pregnancy. The blood pressure and urine were normal throughout. The external measurements were 26, 28, 32 and 20. Was delivered February 1, 1924, of a baby girl weighing seven and one-fourth pounds, after being in labor for four hours.

CASE 2.—History.—Mrs. E. A. M., a nurse, gravidara two and para one, aged 28, first came to me at three months. The blood pressure and urine were negative at all times. The pelvis measured 21, 26, 31 and 18.5. Her first labor was prolonged and after a difficult version was

delivered of a dead baby. On December 8, 1923, she came to the office in labor and was immediately sent to the hospital. Within four hours the cervix was almost

completely dilated and remained at this stage for two hours without further progress, in spite of strong uterine contractions. After doing a deep left medio-lateral episiotomy and rather difficult mid-forceps, delivered her of a baby boy weighing seven pounds.

CASE 3.—History.—Mrs. C. K. S., aged 27, para two, was first seen at five months' pregnancy. Urine was normal at all times. The blood pressure was normal up to the latter part of the eighth month, then there was a gradual rise. Patient had convulsions with her first baby and was delivered by difficult version and extraction. External measurements were 25, 28, 35, and 21. September 23, 1923, quinine and castor oil were given in an effort to induce labor. On the following day she began to have pains. The position and presentation was O.L.P. After two hours of strong uterine contractions in the second stage of labor without any progress, the head was rotated, manually, into the transverse diameter, the forceps applied in the oblique, and a nine and one-half pound boy delivered.

CASE 4.—History.—Mrs. E. L., aged 25, para four, first seen at the dispensary during the last month of pregnancy. On January 8, 1924, a diagnosis of breech presentation was made and this was immediately verified by the aid of the x-ray. The patient was at term and because of previous difficult labors was advised to enter the hospital.

Fig. 1. This is an x-ray film of the patient (Case 1) taken December 23, 1924. It shows a perfectly normal pelvis, an average sized baby, with sufficient room for the presenting part to pass without difficulty.

Fig. 2. This film was made November 30, 1923, and shows a common form of contracted pelvis. It is high and narrow, the hip bones do not have the normal flare, and the inlet is larger than the outlet, giving the form of a masculine or funnel-shaped pelvis. The head is riding high, and although of average size meets with considerable difficulty at the outlet.

Fig. 3. X-ray pictures were taken September 7, 1923. The one illustrated here shows the spine of the baby pointing towards the spine of the mother, making this an occiput posterior position. An antero-posterior picture was also taken and this showed the spine of the baby to be on the left side of the mother. From both films it was obvious that the position was O.L.P.

Two days later she was admitted and the diagnosis of vertex presentation was now made. This also was checked up by an x-ray film.

Fig. 4. An antero-posterior view showed a normal pelvis, a good sized baby, breech presentation, with back towards the left side of the mother. The other film, which was made at the Ancker Hospital two days later, showed the head deeply engaged within the pelvis.

Fig. 5. This film was taken June 23rd, and clearly shows two babies each presenting by the vertex. One head is deeply engaged while the other is at about the level of the umbilicus. The babies are small and from their position should give no difficulty at the time of delivery.

Comment.—Case 4 is interesting in that it demonstrates the fact that a breech may correct itself at any time, even within a very short time before labor begins. Most breeches diagnosed early in pregnancy rotate before labor sets in if there is no special cause for their presenting as such. However, in cases due to some special cause, such as hydrocephalus, short cord, cord around the neck, etc., they usually remain and deliver as such.

CASE 5.—History.—Mrs. C. H., para three, aged 26, first came to the Ancker Hospital Dispensary in her eighth month of gestation. The blood pressure was 150 over 80 and her urine showed a trace of albumin. Abdominal examination revealed two palpable heads, multiple small parts and two distinct fetal hearts. The diagnosis of twin pregnancy was made and immediately confirmed by the aid of the roentgen-ray.

CASE 6.—History.—Mrs. A. P., para one, aged 19, was first seen at the Ancker Hospital Dispensary at seven months. Her measurements were normal. Blood pressure was normal and the urine negative until one week before delivery, when it showed a heavy trace of albumin, some leucocytes and occasional casts. The patient complained of frequent dizzy spells for a period of two months before labor set in. An examination showed the abdominal and uterine muscles to be very rigid, so that it was difficult to

Fig. 6. The illustration shows an abnormally large head, irregular in outline, and a comparatively small body. The irregularity of the head is due to absorption of some of the cerebral fluid, giving rise to some overriding of the bones.

make out the small parts. The heart tones could not be determined, although the patient claimed to be feeling life. From the size and consistency of the presenting part at the brim, and because of the persistent absence of fetal heart tones, the diagnosis of a dead hydrocephalic baby was made and this confirmed by the aid of a roentgenogram. May 14th the patient was delivered of a dead hydrocephalic.

CONCLUSIONS

1. The foregoing observations aim to emphasize the fact that the frequent employment of the roentgen-ray is a necessary procedure.

2. The cautious use of the x -ray at any time during gestation is not harmful in the least to the baby.

3. It helps to determine those findings which are looked for during the prenatal care of a patient. Pregnancy, with its normalities and many of its abnormalities, and its differential diagnosis, may be determined in this way with the greatest possible degree of accuracy.

4. In any case which hints a possible difficult delivery or abdominal section, the use of the x -ray is not only desirable but essential.

5. Its employment for the first time is certain to give more information than was originally looked for and will prompt the desire to employ it more in other cases, even though the indications be less urgent.

Prophylactic Inoculation of Dogs Against Rabies.—The evidence for the efficiency of prophylactic immunization in persons bitten by rabid animals has long been too convincing to permit of doubt. In Japan experiments to reduce the frequency of rabies by inoculation of the dog population show that its frequency with dogs has been greatly reduced (Jour. A. M. A., July 5, 1924, p. 44).

"Sero" Endocrine Preparations.—A circular "For Endocrine Therapy" bears the name of R. A. White, Los Angeles, and Cal. Endocrine Foundation Laboratories, Long Beach. It advertises "Asthma Sero," "Antitoxoid in Tuberculosis," "Rheumatism Sero," "Nephro Sero," "Pneumonia Sero," "Abscess Sero," "Tabes Sero" and "Malnutrition Sero." In connection with each product appear words which, if read hurriedly, might be taken by some as a statement of composition. For instance "Antitoxoid in Tuberculosis" is said to contain "Orco-plasm, Thyroid Extract and Phosphor Iodide." "Rheumatism Sero" is said to contain "Orco-plasm and Thymus Iodide." The circular contains the vague statement that orco-plasms are compounds that "represent unchanged protoplasm and serologic organic and inorganic substance." It contains also the unenlightening statement that "the Inorganic Substances in the Seros are in form Physiological Solutions." The circular wisely makes no attempt to define "phosphor-iodide" and "thymus iodide" (Jour. A. M. A., July 5, 1924, p. 58).

INTUSSUSCEPTION IN INFANCY*

W. B. GRISE, M.D.

Austin Clinic
Austin, Minn.

Intussusception, the condition where one portion of intestine slips into an adjoining segment causing a tumor and obstruction, is not common, but one of the most dangerous of acute abdominal conditions met in infancy. My object is to review the subject briefly, emphasizing especially the importance of early recognition of symptoms, early diagnosis and treatment, thus giving the infant the best chance of recovery.

The high mortality in intussusception reported during the last twenty years is due mostly to two factors—the tender age of the patients, and the late diagnosis and treatment. In one series of 374 cases, extending over twenty years—reported from St. Thomas Hospital, London—the average mortality was 32 per cent. Beginning in 1898 with 48 per cent this had decreased by 1918 to 19 per cent. In other cases reported, one group of 112 cases from the Children's Hospital of Boston, had a mortality of 39 per cent. One of twenty-three cases reported by MacAuley had 17.3 per cent. The lowest was a group of twenty cases reported by Goldschmidt in which only 5 per cent were fatal. Thus we see that the death rate has been very high but also that this has gradually decreased in recent years. It is my opinion that our present statistics would show a mortality rate considerably lower.

Over one-half of all cases of intussusception occur before the ninth month and about three-fourths before the second year. It is two or three times more common in males than females. The younger the infant the more rapid the course.

The types in the order of frequency in which they occur are as follows:

1. The ileo-cecal (about 80 per cent). In this the cecum with the ileum behind it passes into the colon, the ileo-cecal valve continuing to be the apex of the projecting portion.

2. The ileo-colic, in which the ileum passes through the ileo-cecal valve, the ileum being the prominent protruding part.

3. The colic, limited to the large intestine only.

4. Ileac or enteric, limited to the small bowel.

*Read before the Southern Minnesota Medical Association, Mankato, May, 1924.

The occurrence of this condition in infancy is due to the weaker development of muscle and elastic tissue and a correspondingly thin intestinal wall. At birth the colon and ileum are almost the same size and by the fourth or sixth month the colon is three or four times as large as the ileum. The rapid growth and increasing disproportion between the diameter of the large and small bowel is usually accompanied by a large relaxed ileo-cecal valve. The colon in these cases usually has a long swinging mesentery. In many instances the ileum enters the cecum not at a right angle as normally but almost in a straight line. Other causes are given such as abnormal peristalsis due to undigested food; any intestinal irritation or foreign bodies; trauma or local meteorism.

The onset is sudden in most instances. There is scarcely any other condition in infancy which strikes so quickly from a clear sky. It usually begins with sudden, violent, abdominal pain, accompanied or followed shortly by vomiting. These two symptoms are almost always present. At this time there are usually one or two stools containing fecal matter. Later, stools of mucus, mucus streaked with blood or even pure blood may appear. This is accompanied by pallor, anxious facial expression, general muscular relaxation and shock. The prostration is often out of proportion to the other symptoms. Usually there is marked restlessness early, but later, apathy and dullness. The temperature is not elevated the first twenty-four hours and may be even sub-normal. The abdomen is most often relaxed, later is usually distended, and a tumor can often be felt on palpation.

1. Pain is rarely absent and is a prominent symptom in over four-fifths of all cases. It comes suddenly, may be uninterrupted at first but later is usually intermittent in character, varying in intensity but inclined to come at rather regular intervals. This is accompanied by high pitched crying, either continuous or intermittent, the infant often assuming peculiar positions, frequently the prone. The face is usually pinched and pale and shows plainly that the child is suffering. With beginning collapse the pains may be indicated only by regularly repeated moans and the drawing up of the legs. In a few hours the pain and symptoms of shock may disappear for a time, which may be due to an edema of the bowel; this is a deceptive lull should the physician see the baby at this time.

2. Vomiting, present in four-fifths of the cases

reported, is reflex in character, is usually early but may be absent until the second day. In a few cases there was none. It may occur at intervals or be almost continuous, and is more constant if the invagination is in the small bowel. It is aggravated by food or laxatives. It must be remembered that although vomiting is a common symptom in infants, in this instance it is usually more urgent and comes in an otherwise healthy baby.

3. After the lower bowel is emptied of fecal matter, the stools in acute cases with complete obstruction have no fecal odor and there is absence of gas by rectum. Blood in the stools is one of the most important and frequent symptoms and may vary from a few streaks to a severe hemorrhage. It was present in over 76 per cent of cases. It may be absent until the second day. In the sub-acute type the blood may cease for twenty-four hours, only to reappear.

4. The abdomen is usually soft, giving little resistance to palpation the first twenty-four to forty-eight hours. It may be retracted. There may be tympanites—especially the second or third day; its absence, however, is of more diagnostic value. A tumor can be felt in about 86 per cent of cases. It is often sausage-shaped but it may be only an insensitive mass. It is felt more easily during an attack of pain, for the consistency varies at times due to the spasmodic contraction of the intestinal wall. It may suddenly become soft and seem to disappear. It is most frequently felt on the left side. It may be localized at one time and later seem to be movable so that it can be palpated in any part of the abdomen. In a small percentage of cases it can be felt by rectum. Protrusion of bowel through the anus is a late symptom and indicates an invagination low down, or the telescoping of long areas of intestine. Localized tenderness is of some importance in the absence of a palpable tumor.

For reasons mentioned above an early diagnosis is urgent. One must rely much on the mother's history of the onset. In the presence of the four principal symptoms—pain, vomiting, abdominal tumor and discharge of blood and mucus from the rectum—diagnosis is not so difficult. Unfortunately, many cases do not have the typical onset and symptoms, and to catch these cases early, one must be on the alert and exercise extreme judgment in any acute abdominal condition. Failure in diagnosis is most often due to a tendency of physicians

to interpret active vomiting, with green mucus and bloody stools, as significant of a gastro-intestinal intoxication. Other conditions that might be confused with it are: volvulus, hemorrhoids, hernia and appendicitis, the latter being much less frequent in infants. As an aid in diagnosis an opaque enema is very important as it shows the exact location of the invagination. This is best given with a very small catheter to prevent straining. The fluid should flow in slowly, and under the fluoroscope, using gentle pressure to push the opaque contents along the colon, a conical shadow appears at the point of obstruction. If there is no obstruction the opaque enema will go through the ileo-cecal valve. (This valve has been found incompetent in 99 per cent of normal infants.)

The treatment has only one object—that of reducing the invagination by medical or operative methods. Either, however, is a mechanical procedure. A few men plead for less haste in using radical methods especially when seen early. Some advise an attempt at reduction with water or air by rectum under slight pressure. The usual method is to use two quarts of normal saline with irrigating can four feet above the body, injected through a good sized catheter, with hips elevated ten to twelve inches above the shoulders. The buttocks are held to help retention, while gentle manipulation of the mass through the abdominal wall is made. This procedure is more safe and successful if used with light anesthesia. Some advocate small doses of opium to quiet the bowel. This method is useful when the obstruction is in the lower segment of the bowel but must be used early. One objection to its use lies in the inability to control the apparent results. Another is the danger of rupture of the thin bowel. Also, disappearance of the tumor may be due only to a change in its position. If unsuccessful in the first attempt we should at once turn to surgical interference. Modern opinion is tending more and more to the idea that immediate surgical intervention is the best treatment.

I will not go into detail as to surgical procedure but will mention a few things of interest in this regard. About 89 per cent of cases can be reduced by opening the abdomen. Reports show that favorable results depend more on the time elapsing before surgical intervention than on any other one factor. The percentage of recoveries when operated within the first twenty-four hours is about two and a half times greater than if operation comes after

the twenty-four hour interval. The operation should be as short as possible, cutting down the anesthetic to the minimum. The death rate increases directly with the amount of work done. Therefore, there should be as little manipulation as possible, and it has been definitely shown that removal of the appendix or any extra procedure increases the risk. It is important to reduce the invagination from the apex, pushing instead of pulling. If irreducible, reports show it is best to make an artificial opening into the bowel, waiting until later to resect the segment. Most cases under thirty-six hours can be reduced. The proportion of operative cures of intussusception is steadily increasing. This is due not only to improved technique, but in a large measure to more careful attention to early diagnosis.

I will cite but two recent cases to show that we can get results with the more conservative treatment, but especially to stress the importance of early operative interference when indicated.

CASE 1. Herald S., a boy six months old, breast fed. Had a cervical abscess at two months; otherwise healthy. Had been restless and not nursing well and had some symptoms of intestinal irritation for two days, when at 5 A.M. he began crying and seemed in severe pain. The mother gave an enema with no relief. The stool was slightly green. Vomiting began at 10 A.M. At 12 o'clock the baby was taken to a physician, who looked for a hernia as the cause of pain. He suspected appendicitis, but thought it was most likely an ordinary intestinal disturbance. Several enemas during the afternoon and night gave no relief. He continued to vomit and cry with pain, resting scarcely at all. At 8 P.M. there was a stool with considerable blood. The physician saw him again at 6 A.M. and at this time, on account of the continued pain, vomiting and bloody stool, he suspected an obstruction. The baby was sent to the hospital, where I saw him at 10 A.M., twenty-nine hours after the apparent onset. On examination he was pale, slightly drowsy and in evident distress. The temperature was 103.8 degrees. The abdomen was relaxed, a tumor cylindrical in shape, about three inches long and movable, was felt on the left side at a level with the navel. This was not felt by rectum. A saline enema was given as described above, and on gentle manipulation the bowel was definitely felt to separate and the tumor disappear. The baby was more comfortable and slept well. In a few hours the stools began to show fecal matter, although the blood continued in small amounts for thirty-six hours. The temperature dropped to 101 the same day and to normal the second day. He left the hospital in good condition the fourth day.

CASE 2. Eugene C., a normal breast-fed boy of five months. Had whooping cough at one month. He had a nasal and ear infection for three days, when, while sleeping, at 11 P.M., he suddenly began to cry bitterly. He writhed and squirmed in severe pain continuously for thirty

minutes. He then became quiet and was drowsy and pale during the night. He slept some but was restless at intervals. There was considerable retching but he was unable to vomit. One hour after onset there was a greenish liquid stool of fecal matter. At 7 A.M. a second stool containing only mucus streaked with blood. I saw the boy at 8 A.M., nine hours after the onset. He was restless, pale, with considerable prostration and muscular relaxation. The abdomen was flaccid, a prominent mass could be seen just below the navel in the midline. This was rather firm, sausage shaped and freely movable, and could not be felt by rectum. The temperature was normal and pulse only slightly accelerated. During examination there was some attempt to vomit and a large bloody stool with no fecal matter or flatus. At 10 A.M., eleven hours after the onset, he was given a saline enema under considerable pressure and on manipulation the mass was felt to disappear, and it was supposedly reduced. The baby was more comfortable and had less evidence of shock. He passed some flatus and fecal stools during the day with but streaks of blood. There was no vomiting. No tumor was felt on careful palpation on several occasions during the day and evening. The abdomen was slightly tender with beginning tympanites. At 7 A.M. the following morning, the boy became more restless, tried to vomit, and there was a large bloody stool. He again showed more prostration and a mass was now felt low on the left side. This was not reduced by enema. Laparotomy was done thirty-eight hours after the onset and an ileo-cecal invagination was found with the valve and appendix carried along in the colon to the descending portion. This was reduced without difficulty and the appendix removed. The mobility was due to a very long mesentery along the cecum and entire colon. The boy made an uneventful recovery, leaving the hospital the eleventh day. In this case, although the symptoms improved and the boy was definitely better, the question remains as to whether the invagination was even partly reduced at the first attempt.

DISCUSSION

Dr. F. C. Rodda, Minneapolis: It is a pleasure to discuss the excellent paper of Dr. Grise since it is a subject in which I am much interested.

We are much indebted to Dr. A. W. Abbott for his careful observation and report of twelve cases made before the Western Surgical Association in 1915. He showed us a clear, clinical picture of intussusception in infancy which briefly is as follows: A normal infant, without premonitory symptoms, suddenly cries out with pain and presents collapse symptoms of pallor, depression and perspiration. This stage is soon recovered from, but it is followed by periodic attacks of pain during which the infant draws up its legs, or if old enough assumes the knee chest posture. Between the attacks of pain, the child may appear well and react normally. There is no fever. After some hours there *may* be vomiting and there *may* be passage of bloody mucus from the bowel. The symptoms are so clear-cut that in our series of cases the diagnosis has been made by the mother in three instances—once in a recurrence in the same child, once in a second case occurring in the same family, and once by a mother who had been a nurse.

Aside from the classification with reference to the portion of the gut involved there are three types: (1) acute, with profound persistent collapse; (2) acute, with moderate symptoms of collapse at onset; (3) chronic.

It is not sufficiently widely recognized that there is a type of this disorder which may last for days or even weeks. We have had three such cases lasting from six days to as long as three weeks. Bergstrom in the May, 1924, number of the *American Journal of Diseases of Children* reports four cases lasting from eight to sixteen days. These cases vary from the acute ones only in that there is not a complete obstruction of the bowels.

The basis of my discussion is a series of twenty-six cases which have been observed personally.

Age incidence.—Nineteen were in infants six months to one year old; three were in infants under six months; and four were in infants over one year.

Subjective symptoms.—

- (a) Pains. All had the characteristic pains.
- (b) Vomiting. Several did not vomit at all and often it was a late symptom.

Objective findings.—

- (a) Tumor. In not every case was the tumor palpated. It is most easily palpated during an attack of pain. In very late cases, it may be felt by the rectum. X-ray examination may give confirmatory evidence when the mass has been recognized through the abdominal wall.
- (b) Blood from the bowel is usually found in small amounts if looked for early. Subsequently, in the mild, acute cases and in the chronic cases it may not reappear for days. It is not pathognomonic.
- (c) Posture. Abdominal pain as evidenced by position of the legs and the posture is always found if the child is watched for a long enough period.

Failure to find the tumor at the time of operation does not nullify the diagnosis. Due to the relaxation produced by the anesthetic and traction on the bowel, the tumor may not be delivered in the abdominal opening. But careful search will show an edematous, dark-colored bowel where the mass had been.

Complications.—We had one recurrence in the same child one month after the primary operation. The mass was reduced a second time, and the child made a complete and permanent recovery. There were two cases of evisceration from the opening of the operative wound. These wounds should be closed with appropriate retention sutures.

Mortality rate.—We consider operation the only safe and sane treatment. Of the twenty-six cases operated upon, five died,—a mortality rate of 19.2 per cent. A number of factors enter into the mortality. Other things being equal, the earlier the diagnosis is made and operation resorted to the greater the chances of a speedy recovery. But in some of our cases, even at early operation, the mass could not be reduced and the bowel was gangrenous, while in cases lasting many days the mass was easily reduced and the bowel showed little damage. It is largely a question of mechanics. A strangulated bowel means a grave prognosis.

Nicomors.—The Council on Pharmacy and Chemistry took up the consideration of Nicomors, stated to be a medical preparation for the alleviation of the physiologic effects of nicotine at the request of the Nicomors Products Company. Nicomors comes in the form of tablets which are claimed to contain magnesium peroxid and tannic acid as their essential constituents. It is claimed that with the use of Nicomors the effects of tobacco smoking show very little or not at all. It is even claimed that the preparation has a favorable effect on the stomach and the intestines. The Council reports that the claim that the random use of a mixture of magnesium peroxid and tannic acid has a favorable effect on the stomach and intestines, is without warrant, and that the claim that the ill effects of tobacco smoking can be overcome by the use of Nicomors is not credible and not supported by any acceptable evidence (Jour. A. M. A., July 19, 1924, p. 212).

THE INTERPRETATION OF ABDOMINAL PAIN IN CHILDREN *

THOMAS MYERS, M.D.

St. Paul

It being manifestly impossible to do justice to so extensive a subject in a brief paper, only some of the commoner conditions, the causes of which are frequently overlooked, will be emphasized.

Abdominal pain, as a symptom of trouble not necessarily within the abdominal cavity, occurs perhaps more often in children than adults; at the same time, it less often points to surgical conditions within the abdomen than is the case with adults. To some extent, diagnosis is simplified as compared with that in adults. Cholecystitis, cholelithiasis, gastric and duodenal ulcer, carcinoma of the abdominal organs, affections of the female pelvic organs, and tabes dorsalis, so commonly causing abdominal pain in adults, are exceedingly rare in childhood. On the other hand, it must be borne in mind that acute surgical conditions in children require prompt diagnosis, as usually they will not tolerate temporizing to the extent possible with adults.

Because of the tendency for various affections to apparently cause reflex pains in the abdomen, and because of the difficulty in getting the average small child to coöperate in localizing the pain, particular care must be exercised in making the diagnosis. This is commonly not easy, for in addition to the task of evolving a satisfactory history from the nervous mother, there is the inability or unwillingness of the small child to permit a careful examination of the abdomen. Generally the little patient will not do more than vaguely point toward the mid-abdomen as the location of the pain; commonly he will, by crying, make the examination very unsatisfactory. Not the least essential part of the physician's armamentarium, therefore, is an appreciation of the psychology of the average child; he should proceed deliberately and casually to become acquainted with the child, and gain its confidence; *then* examine the rest of the body, leaving the abdomen to the last. Realizing the susceptibility of the average child to suggestion, he must always be on his guard against prompting admissions without basis.

*Presented before the Ramsey County Medical Society, May 26, 1924.

In infancy, *colic* is the most common abdominal pain. This is most frequent in the first three months of life; it usually occurs at the same time daily—has a predilection for the afternoon and evening. The pain is paroxysmal, appearing and leaving suddenly; it is usually relieved by pressure or removal of flatus. Fever is absent. It is due usually to distension of the intestines. Gastric colic may occur, due to over-distension of the stomach by food, gas or air, and appears during or just after feeding. A pathologically tight anal sphincter may cause severe paroxysmal pains with severe distension of the colon; it is promptly relieved by the rectal tube.

Colic covers a multitude of diverse conditions in infants. Most babies tend to draw the thighs upward when crying, which is immediately interpreted by the onlookers to mean that the baby has pain in the abdomen. The trouble may be due to hunger, distress from overfeeding or too frequent feeding, indigestion from improper milk mixtures, constipation or diarrhea, with attendant gas formation. an over-tight belly-band, too much clothing and covers, eczema or chafing, otitis media, neuropathy (the desire of the spoiled child to be rocked), painful dentition, rickets, or scurvy.

Pylorospasm and *pyloric stenosis*, frequently manifesting themselves during the first three months of life, may cause cramp-like pains accompanying the peristaltic waves of the stomach, and are usually relieved temporarily by vomiting of a projectile type. These waves can often be seen through a thin abdominal wall, long before a pyloric tumor can be palpated.

Intestinal intussusception, comparatively common in infancy and early childhood, does not always cause severe paroxysmal pains after the onset. A mild pain may appear subsequently at fairly regular intervals, shown by only slight squirming or wincing on change of position. The child may cry for a moment until relieved by emesis. Shock is very often absent. The child usually lies quietly, preoccupied, not playful or normally interested in his surroundings. A toxic look often develops, especially later. Tympany is usually absent. It is necessary to distinguish this condition from enteritis or colitis, as often stools are passed, or produced by enemas, which contain blood. In enteritis the blood and mucus are quite separate from the feces; in intussusception the first stool or two may be normal, but the later ones con-

tain considerable blood and thin jelly-like mucus, intimately mixed with the feces, and possess a characteristic fleshy odor. Occasionally blood may not appear if the ileo-cecal valve is held closed, and not much of the colon is involved.

It is most important to seek the typical sausage-shaped tumor; this may be hard to make out because of the muscle spasm in the abdominal wall, or if too high in the abdomen, or too low in the pelvis. A general anesthetic may be necessary for satisfactory examination. Rectal examination is very important, but may be negative if the mass is high in the abdomen. Rectal examination can be practiced on even small infants, and is valuable in many conditions. Thorough lubrication of the examining finger is essential, and the little finger should be used when possible, that tears of the rectal mucosa with resulting bleeding may not thus occur to confuse the examiner. The tumor in intussusception may at first be felt in the transverse colon; later in the descending colon or rectum; it may even protrude from the anus.

The following case illustrates problems arising in diagnosis:

CASE 1. H. W., male, age ten months, weight 23 pounds. Previous history largely negative. He was doing well until suddenly at noon he began to vomit forcibly every hour or hour and a half. He would wake suddenly with a cry, and double up as though in pain, relieved for a while by emesis. The vomitus included bile. He had frequent hiccups and seemed weak and exhausted. He was seen by Dr. T. L. Birnberg at 6 P.M., who ordered an enema; this produced a dry, hard stool, followed by a large soft stool mixed with bright red blood and serum. He seemed better thereafter, did not cry, was more playful and apparently had no more cramps. Vomiting stopped for one and a half hours, when he vomited twice. He took water freely and retained it.

Examination showed a well nourished child, slightly fussy, but whose attention could be distracted by toys. The head, throat, and chest, were entirely negative. The abdomen was relaxed, soft and not tender on the left side. The right rectus was rigid and tender, just above the umbilicus, and while a definite mass could not be felt due to the rigidity, surgical pathology was suspected, and operation was advised. As the child seemed so much better since giving the enema there seemed a strong likelihood that an intussusception had occurred and had been relieved, and the parents were at first strongly opposed to operation. The rigidity in the right rectus, even though no mass could be felt by rectum, suggested that waiting was not justifiable, and the abdomen was opened by Dr. W. C. Carroll. Under the anesthetic a mass could be made out under the right rectus more easily, and this was found to consist of about six inches of the ileum invaginated into the cecum. This was separated without difficulty. The appendix was dark red and angry looking but was not removed. A complete recovery ensued.

Subacute intussusception as described by Bergstrom² causes intermittent and less severe pain; the vomiting is not continuous; the shock is less severe; repeated bloody stools are usually present. Obstruction is not complete, so less gangrene develops, and the diagnosis is often delayed until the condition is present a week or more. An abdominal tumor can usually be made out, although the assistance of a general anesthetic may be required.

Recurrent partial intussusception occurs more often than is recognized. It is characterized by repeated attacks of severe cramp-like pains across the abdomen, emesis, constipation, blood-streaked stools at times, and occasionally accompanied by a palpable tumor in the upper abdomen which disappears spontaneously. These attacks may recur every few months and may terminate in a complete intussusception, or require fixation of the ileum to the cecum and ascending colon to prevent recurrence. The following case illustrates the condition:

CASE 2. J. G. C., male, age eleven months, weight 18 pounds. He is being nursed seven times daily; gets no other food. Appetite is fair. Sleeps poorly. Nervous and irritable. Usually constipated. About seven weeks ago began to have attacks of colic accompanied by moderate vomiting; three of these occurred about one week apart. A month ago he had measles and five days later he had severe pains in the abdomen, off and on, for three or four days; vomited repeatedly; was blue, cold, and unconscious for a few minutes at a time. The mother said a mass could be felt in the region of the stomach for a few hours. He was given enemas to relieve him, producing stools containing blood and mucus, but very little fecal matter at first. The condition then improved and he was well, aside from constipation, until twelve days ago when he had another attack, lasting three days. He had severe pain at intervals, with frequent vomiting, and slight fever. Bright red blood appeared in the stools twice on the first night. The mass appeared several times during the attack. He was blue, cold and unconscious during the pains for a few moments according to the mother.

Treatment to prevent recurrence consisted in slowly adding solid food to his diet. This relieved his constipation, enabled him to put on weight, and improved his disposition. The increase in diet should serve to thicken the mesentery with fat and so lessen the likelihood of recurrence. No attacks have occurred since.

Abdominal pains accompanying *acute grippal infections, tonsilitis, etc.*, are very common in childhood, as has been emphasized by Brenneman³. The pains are usually intermittent, may be quite severe, and often give the patient much more concern than the underlying infection. They are usually located near the umbilicus but occasionally are diffuse or on one side. The pain is much worse

than the tenderness, quite the reverse of the case in appendicitis. It is probably due to inflamed mesenteric and retroperitoneal glands, which have been found in such cases where laparotomy was mistakenly done or when coming to autopsy. Infection of the glands may be hematogenous or due to swallowing of bacteria. Occasionally these cases also present diarrhea and vomiting, representing the cases probably justly called intestinal influenza. Peritonitis has been known to occur due to supuration of such a gland. The pain seldom outlasts the other evidences of infection. When prolonged it may be responsible for the so-called umbilical colic of unknown cause.

Lobar pneumonia causes abdominal pains so frequently in children, and is so readily mistaken accordingly for appendicitis, that their differential diagnosis is worthy of careful consideration. Diaphragmatic pain referred to the right lower quadrant of the abdomen, associated with vomiting, frequently is the initial symptom of pneumonia, and as Riesman⁹ said recently, "There is but one good rule to follow, and that is in every case of acute abdominal trouble to make a thorough examination of the chest."

White¹⁰, Hagaman⁶, Adams and Berger¹ have likewise emphasized the frequency with which pneumonia may simulate appendicitis. The last mentioned observers reported observations on a series of 145 cases of lobar pneumonia, of whom only sixty-six, or 45 per cent, were sent in with a diagnosis of pneumonia, while twenty-five, or 17 per cent, were sent in with a diagnosis of appendicitis. The latter figure seems far higher than is our experience, but illustrates how often these conditions are mistaken. It is quite likely that not a few of the cases of so-called ether pneumonia are actually primary pneumonias, operated on mistakenly for supposed acute abdominal pathology. Adams and Berger present admirably the differential diagnosis which is herewith in part quoted:

PNEUMONIA	APPENDICITIS
<i>Chest Pain and Cough:</i>	
Usually, but not always, present or ascertainable.	Almost never present.
<i>Abdominal Pain:</i>	
Often present (34 per cent of series). Usually higher in abdomen. Usually worse on inspiration. Often more severe and distressing. Lasts several days.	Always present. Usually lower in abdomen. Not affected by inspiration. Often intermittent.

PNEUMONIA

APPENDICITIS

Emesis:

Quite frequent (60 per cent), especially at onset.

Occurred in 68 per cent of cases.

Appearance:

Look very sick; flushed; fussy and irritable; toss about in bed.

Do not look so sick (except in severe cases). Lie quietly; no complaint (except when abdomen is palpated).

Respiration:

Short, rapid, shallow, with an expiratory grunt. Abdominal breathing; alae nasi dilated.

Quiet, not very rapid. Breathing tends to become costal in type later.

Temperature:

Usually 103° or above.

Often not over 99°, rarely 101°.

Pulse:

100 to 140.

Seldom over 100 to 110.

Onset:

Usually preceded by a cold.

No preliminary illness.

Respiration-Pulse Ratio:

Usually increased from 1:4 to 1:3, or 1:2.

Usually normal, 1:4.

Leucocyte Count:

Usually over 20,000.

Seldom over 20,000, unless abscess is present.

Lung Signs:

Definite signs are absent in 40 per cent during early stage.

Absent.

Tenderness in the Abdomen:

Tenderness seems more severe and more superficial, is not well localized, but is diffuse over a fairly large part of the abdomen, although varying in degree. Is usually higher in abdomen.

Pressure on left side causes no change in the pain.

Rectal examination is negative.

Tenderness may be slight, is not as general or as severe; is more readily localized usually to a small area in the right lower quadrant. It is deeper in abdomen and required often deeper pressure to be elicited. Is usually near McBurney's point, though in children may be higher. Pressure on left side of abdomen often causes referred pain in the right side. Rectal palpation often reveals local tenderness on right side.

Rigidity:

Often more severe than uncomplicated appendicitis.

Often very little rigidity, especially in early stage; increases if abscess or peritonitis threatens.

It is thus seen that pain, tenderness, rigidity and vomiting often accompany pneumonia, particularly when the process is in the right base; that the patient usually looks much more acutely ill than the

average case of appendicitis, and the change in respiration is all-important as a differentiating symptom. Finally, however, the safest procedure is to always require an x-ray picture of the chest if possible, before operating for appendicitis in children.

CASE 3. H. J., male, age two and three-fourths years. Two weeks ago while out of the city he was taken sick suddenly with severe pains in the abdomen; temperature was 106° to 107° for two days. No vomiting occurred. The pains lasted for two days, but he complained of soreness for a few days afterwards. The mother states that he would cry out and hold his sides whenever he would cough or breathe deeply. The case was diagnosed as stomach trouble. Since then he has been weak, pale, tired, wants to be held, refuses food, breathes rapidly, and is short of breath frequently. He contracted a slight cough just before his illness, but it was at no time very severe.

He was then seen by another physician, who, according to the mother, did not take his temperature or examine the chest, but diagnosed stomach trouble. When seen by us two weeks after he first took sick his temperature was 100.7° rectal; the chest showed complete flatness of the entire left side, with some displacement of the heart and distant bronchial breathing over the left lung. X-ray showed effusion almost filling the left chest. The Pirquet test was positive. Aspiration revealed considerable thin, clear, yellow fluid. The diagnosis was evidently lobar pneumonia with tuberculous pleurisy. The child has since improved considerably under rest and building-up treatment, with ultra-violet ray exposures.

In early appendicitis the pain is often referred to the epigastrium or umbilicus. Occasionally in young children the appendix is found higher and to the left, where it lies during fetal life, and may thus give atypically located pain and tenderness. Pain is much more severe in obstructive appendicitis due to a concretion. Emesis is much more frequent in children than adults, and, according to Fraser⁵, if vomiting is severe, it suggests distention of the appendix by its contents, and probably early perforation. Pelvic appendicitis may cause pain on urination, if the appendix lies against the bladder, or diarrhea if near the rectum. If near the obturator internus muscle it causes rigidity, and consequently pain on flexing the thigh inwards. The retrocecal appendix often causes pain and tenderness largely in the back, and may not cause emesis. Early diagnosis is essential in appendicitis in childhood, as rupture of the appendix frequently develops in twenty-four hours or less; furthermore the omentum is short, thin and veil-like in early childhood, and does not provide the protective power exhibited by it later. In consequence general peritonitis is a more common and earlier

development than in adults, and the relatively lower resistance to general acute toxemia gives it a much more ominous portent.

Inflammation of *Meckel's diverticulum* should be properly mentioned, as the pain, as well as the other symptoms, is seldom distinguishable from that of appendicitis. While a rare condition, the majority of the cases occur in children.

Green-apple colic, as well as that arising from other dietary indiscretions, occurs mainly in older children, and may cause very severe colicky pains, accompanied by vomiting, diarrhea, fever and occasionally convulsions. The pains are usually in the stomach region, and tenderness is usually absent. The history of the offending food, together with the relief usually produced by removal of it, generally clears up the diagnosis.

Tuberculous peritonitis is more common in children than adults, probably because of bovine tuberculosis transmitted by milk; also because sputum is swallowed more than by adults. It causes chronic abdominal pains, varying in every respect, especially depending upon the stage of the disease—whether distention, effusion or adhesions are present. The indefinite doughy masses often palpable, with the insidious onset, slight fever, and positive Pirquet test, assist in the diagnosis.

Acidosis frequently is accompanied by severe pains across the middle of the abdomen centering around the umbilicus. Nausea and severe repeated vomiting occur, with temporary relief of the pain by emesis. Children frequently confuse nausea with pain, thus misleading the examiner. Later severe pain may be due to straining of the abdominal muscles by repeated vomiting, and superficial tenderness may be present. The child is drowsy and often looks very ill; the abdomen is retracted, fever is usually present; acetone is present on the breath and in the urine. The alveolar air shows a low carbon dioxide tension.

Recurrent acidosis, or cyclic vomiting, may present the foregoing picture frequently, as any acute infection or digestive upset may precipitate an attack. Prompt measures to restore the disturbed metabolism and neutralize the ketone bodies are necessary, as very severe prostration or death may ensue.

Pyelitis and pyelocystitis occur frequently in childhood and are a frequent cause of abdominal pains not apparently associated with the kidneys.

Occasionally the pains are very sharp; they may be sufficiently severe to draw the attention away from other symptoms. More often they are vague and indefinite, usually near the umbilicus, but also often over the kidney regions. The pain is usually relieved by urination. High fever, vomiting, marked malaise, frequent burning urination and a peculiar pallor generally accompanying pyelitis. The condition is frequently overlooked because of the failure to obtain specimens of urine from small children, particularly girls, in whom 75 per cent of the cases occur. Pus may not be present at the onset in a few cases, but the urine will be swarming with colon bacilli, as has been shown by Ramsey⁸. The following case illustrates the difficulty occasionally present in attributing the pain to pyelitis.

CASE 4. D. K., female, age six years. She has had frequent attacks of severe pain in the abdomen for about three years. Previously they occurred about every three months, lately every two or three weeks. The pains last about two hours, do not radiate or cause her to double up. She usually vomits several times during the attack, is sometimes feverish, and the abdomen is very tender for a few hours afterward. Urination is usually frequent. About one and a half years ago the condition was diagnosed as appendicitis and operated, but no particular relief was obtained. When first seen by us she was in a typical attack, and the urine was full of pus. Under appropriate treatment she has improved materially and has had no attacks for over two months, while the urine is almost normal. There have never been red blood cells seen in the urine. X-ray picture and Pirquet test were both negative.

Calculi in the kidney, ureter and bladder occur occasionally in children, and cause severe paroxysmal attacks of pain, with fever and pyuria; usually a little blood may be found in the urine. The pain tends to locate more in the abdomen than in adults. The following case is illustrative.

CASE 5. J. C. F., boy, age six years. He recently contracted mild scarlet fever and, while convalescing, red and white blood cells were very frequent in the urine; but very few casts and only a little albumin were present. During the following month he developed two attacks of severe pain in the mid-abdomen radiating down the bladder region, or passing from the genitals around the anus and up the sacrum, occurring just after urinating. On one occasion he had pain in the right side of the abdomen for a half hour, not related to urination. The urine showed considerable pus and blood, but no casts and only a faint trace of albumin. An x-ray picture showed a stone at the junction of the right ureter and bladder, and when repeated a month later, was unchanged in position or shape. Operation has been advised.

Acute ureteritis may present symptoms exactly like those of an actual stone in the ureter; it may also simulate appendicitis. It may follow the pass-

ing of a stone, or may be due to bacillus coli infection.

Pain due to a distended bladder, as pointed out by Brenneman⁴, is not uncommon, and is often due to phymosis, balanitis, or ulceration of the external urinary meatus. The pain may be quite intense, and the infant in severe discomfort until relieved, either voluntarily or by catheter. The abdomen reveals in these cases the typical pear-shaped tumor in the bladder region.

Gastric ulcer, while very uncommon in children, does occur, and presents the usual history of pain during or soon after meals, located in the epigastrium, and relieved by vomiting.

Gastric hyperacidity occurs occasionally in children, and causes a dull, annoying pain above the umbilicus, usually before meals, and especially before breakfast. It is occasionally severe and colicky. The child may be awakened by it. This condition, as pointed out by Kerley and Lorenze⁷ is usually secondary to diet errors, or enteroptosis. Nausea, especially before meals, relieved by taking food may be the only symptom. The appetite is usually poor, eructations of gas, belching, and constipation commonly occur. X-ray examination usually shows a hypo-motility of the stomach and often gastroptosis. The gastric contents show high free and total acidity.

Acute stitch is a common complaint in older children, occurring when running or walking and causing pain below the ribs on either side. It is apparently only a strain of the abdominal muscles, and is not associated with tenderness, swelling or fever.

Retention of the testis may cause severe pain if the testis swells as it may do at puberty. It may cause pain and local tenderness in the iliac fossa. Fever is absent. Examination of the scrotum will suggest the source of the pain.

Henoch's purpura, though rare, deserves mention because it causes severe abdominal pains, with blood in the stool, and thus may be confused with intussusception. A purpuric rash elsewhere on the body makes differentiation possible.

Acute pericarditis may cause severe pain and

tenderness in the abdomen, and, combined with fever and prostration, may often resemble peritonitis. Incompensated heart cases often complain of pains in the abdomen, possibly due to enlargement of the liver, and gas pressure in the stomach.

Umbilical hernia, in older children, apparently causes a chronic vague pain in the mid-abdomen, which may require operation for relief, even though the hernia may be small.

Neuropathic pains, neurosis or hysteria occasionally are the only apparent explanation for some cases of abdominal pain where no definite localization or evidence of organic pathology is present. Such a diagnosis should be made reluctantly in any event, as the probability is that most of these do have some kind of trouble of minor nature, but, occurring in nervous, high strung, temperamental children, born of neuropathic or neurasthenic parents, they have a low threshold of consciousness, and so feel trivial pains much more keenly than other children. Occasionally the pains are fictitious, due to a desire of the child to avoid eating foods he dislikes, or to avoid disagreeable tasks—and the pain is quickly lost when the suspected cause is eliminated.

ATTEMPTED PREVENTION OF MEASLES IN PRIVATE PRACTICE*

STUART W. ADLER, M.D.

Winona Clinic

Winona, Minnesota

It is gradually becoming more generally accepted that measles, with its severe bronchial and upper respiratory inflammation, is no longer to be looked upon as a trifling affair. Because of a heavy death rate among youngsters, and because of the many unfortunate sequelæ, it commands our respectful consideration.

There are several groups of cases which particularly warrant attempted avoidance of this disease. We may mention: babes at breast of mothers known never to have had measles; feeble or debilitated infants or children; children sick with respiratory infections; and, in general, all cases of infants and very young children. There are also those cases where it is particularly desired to do everything which may possibly assist in preventing measles, even when the individual is older or one in good health.

Institutions in which measles as a cross infection is an unwelcome guest have, for a number of years, been successfully using convalescent measles serum as a prophylactic in cases of exposed non-immunes. The experience here and elsewhere has demonstrated quite conclusively that, in proper dose, serum, given within the first four days after exposure, prevents measles. Most authors agree that prevention is unlikely if more than five days have elapsed between first exposure and institution of treatment.

Serum from recent convalescents contains antibodies in such concentration that relatively small doses will afford protection. That taken from persons having had the infection years previous, while containing sufficient protective substance to insure the donor against secondary attacks of the disease, protects others only when larger sized doses of blood or serum are used.

Recent work of the Board of Health of New York City is a notable example of the extension to private practice of the benefits of this preventive. Prepared in a large laboratory, from convalescent measles cases, plasma is now available for the use of physicians in attempting prevention of the dis-

ease among very young children with known exposures. A personal communication from Dr. Wm. Park, director of the bureau of laboratories, states that since January of this year the department has given plasma to about 1,500 little children—as he says “with excellent results, either complete prevention or very, very mild attacks.”

Few, if any of us, can go into the open market and secure serum or plasma. Serum prepared by institutions is rarely available for use outside their walls.

This paper is being presented for the purpose of showing what can be done in private practice with the means at hand. I refer to the injection of whole blood from measles convalescents in the family.

The use of whole blood as described in this paper has been reported by but few authors. Recently Zingher reports the use of the method in thirty-one cases treated in institutions where the exposure had taken place. His cases were injected on the second to eighth days after exposure with an average of 19 c.c. of whole blood. Of this group, three developed measles. They were cases that were injected on the seventh and eighth days. Except for two adults, all were children under seven years of age.

Less favorable results are shown in the cases herewith presented. The results are offered as indicating what may be expected of cases handled under the conditions with which the majority of physicians find themselves working. The situation one meets in attempting this sort of thing in a home is materially different from its application in the infectious disease hospital.

The material presented itself during an epidemic of measles and whooping cough occurring in a city of 20,000. The two infections went hand in hand. Over 500 known cases of measles occurring between January and May, 1924, represents, as usual, but a part of the estimated number.

The data presented are meager for the reason that they were secured by the writer during a very busy period. All cases were handled in the homes and the follow-up work was done whenever opportunity presented. A surprising number of people of the less-enlightened class feel that measles requires no physician, save occasionally for a single visit to diagnose the initial case in the family.

The project was to secure blood from some member of the family for injection into the non-immunes who had had known exposure to measles. It was hoped to procure prevention or modification of the

*Read before the Southern Minnesota Medical Association, Mankato, May, 1924.

measles in the secondary cases. Donors included parents or blood relatives who had had measles at some remote period, and brothers or sisters recently suffering from the infection. In most cases these latter were the source of exposure of the recipients.

The technic is extremely simple. Blood is drawn with aseptic precautions from the arm veins, a 30 c.c. syringe with rigidly attached needle being used. As soon as the blood is secured a second needle is substituted. The injection is made at once, either intra-muscularly or subcutaneously. There has been no difficulty experienced in completing the entire procedure before the blood clots. No citrate was used, for it proved unnecessary. At most but three to four minutes need be consumed in completing the process for one or two recipients.

In only one case was any difficulty encountered in securing the amount of blood previously decided upon. The donor in this instance was four years old.

No reaction followed the injections, and very little discomfort was reported.

The following brief protocols of the cases are summarized in the accompanying table.

Case 1.—R. P., female, aged 2, was under treatment for whooping cough of about five weeks' duration, when she was exposed to measles by her brother, aged 6.

Jan. 17. Brother seen with typical measles in early eruptive stage.

Jan. 21. Brother donor of 20 c.c. whole blood, injected into R. P. intramuscularly without incident.

Jan. 28. Exposure to secondary case in sister seen on this date with full rash of typical measles.

No measles developed in the treated child after either of the exposures. Whooping cough gradually improved. Donor had temperature of 99 and was still coughing on the day blood was taken. He had an uncomplicated recovery.

Case 2.—B. L., male, 14 months old, weight less than 15 pounds. Gave history of several attacks of pneumonia and general weakness. Examination revealed a cleft palate, rickets and definite undernourishment. He could not hold up his head nor sit unsupported.

Jan. 7. Sister, E. L., seen with typical measles in the early eruptive stage.

Jan. 10. Sister had acute otitis media with temperature of 99. Ear opened under chloroform anesthesia and at the same time 10 c.c. blood taken. This was injected intramuscularly into the B. L. without incident. Patient was sent to home in a neighboring town.

Jan. 17. Reported that there was a very sparse rash beginning this date and lasting two days and accompanied by a very slight catarrhal phase with slight cough. Baby was hardly sick at all.

Feb. 12. A few weeks later it was reported that he was gaining weight and was considerably stronger.

Case 3.—D. S., male, age 16 months. About ten days previously had had a severe upper respiratory infection in common with all the other members of the family. Has mild rickets.

Feb. 11. Brother, M. S., had "fever and cold." No Koplik's spots or rash.

Feb. 12. M. S. Koplik's spots seen and sparse eruption on the face.

Feb. 14. M. S. Eruption at its height. Moderately severe measles.

TABLE
RECIPIENTS—MEASLES CONVALESCENT BLOOD

CASE No.	SEX	RECIPIENT		RELATION	DONORS		AMT.	ROUTE USED	INTERVAL	RESULTS
		AGE Mo.	DIAG.		AGE YRS.	HAD MEASLES PREVIOUSLY	BLOOD C.C.		FROM FIRST EXPOSURE	
1.	F	24	Whooping cough	Bro.	6	7 days	20	Intramuscular	7 days	No measles
2.	M	14	Malnutrition	Sis.	10	7 days	10	Intramuscular	7 days	Very, very mild measles
3.	M	16	Grippe	Bro.	6	6 days	10	Intramuscular	6 days	Very, very mild measles
4.	M	36	Grippe	Bro.	6	7 days	10	Intramuscular	7 days	Very mild measles
5.	M	60	Whooping cough	Sis.	6	7 days	10	Intramuscular	7 days	Typical measles
6.	F	24	Whooping cough-pneumonia	Sis.	7	7 days	8	Intramuscular	7 days	Very mild measles
7.	F	60	Malnutrition	Bro.	13	8 yrs.	30	Subcutaneous	4 days	Very, very mild measles
8.	F	12	Well	Sis.	5	8 days	2.5	Intramuscular	8 days	Mild measles
9.	F	30	Well	Moth.	32	22 yrs.	15	Intramuscular	5 days	Very mild measles
10.	F	72	Well	Moth.	32	22 yrs.	15	Intramuscular	5 days	No measles
11.	M	20	Upper-resp. infect.	Moth.	27	20 yrs.	30	Subcutaneous	5 days	Mild measles
12.	F	60	Well	Moth.	24	Childhood	30	Subcutaneous	5 days	Mild measles
13.	M	18	Whooping cough	Uncle	14	6 yrs.	15	Intramuscular	8 days	No measles
14.	M	48	Whooping cough	Uncle	14	6 yrs.	15	Intramuscular	8 days	No measles
15.	M	18	Upper-resp. infect.	Bro.	7	6 days	10	Subcutaneous	6 days	No measles
16.	M	24	Recent whooping cough	Moth.	33	Childhood	30	Intramuscular	4 days	Very mild measles
17.	F	24	Recent scarlet fever	Bro.	16	6 days	12.5	Subcutaneous	6 days	Very, very mild measles
18.	M	96	Well	Bro.	16	6 days	12.5	Subcutaneous	6 days	Very mild measles

Feb. 16. M. S. Temperature 99. Cough still fairly bad. In good general condition. Donor of 20 c.c. blood; 10 c.c. given intramuscularly to D. S.

Feb. 25. D. S. had scant rash on face and body. Koplik's spots present. He was cross, had very slight elevation of temperature, eyes did not bother him. Very slight cough. After one day more of the rash, it faded and he had no other symptoms or signs.

Case 4.—B. S., a male, aged 3. Exposure same as Case 3. Cases 3 and 4 are brothers.

Feb. 16. Ten c.c. blood from same donor as previous case, injected intramuscularly into B. S.

Feb. 23. B. S. had conjunctivitis, Koplik's spots, moderate eruption on face and body. Temperature 102, slight cough not sufficient to annoy patient. He was active and played about. Appetite unimpaired.

Feb. 25. Eruption fading. Not apparently sick at all. Mother's comment about cases 3 and 4: "Neither was what you could call sick."

Case 5.—B. H., male, aged 5. Was in school up to February 4.

Feb. 6. With sister, kept out of school because sister's condition was diagnosed whooping cough. Vaccine treatment was started for both children. B. H. had been coughing for two weeks but on this date neither child showed any signs of measles.

Feb. 13. Sister, aged 6, had a coryza and showed Koplik's spots. She had a very annoying cough.

Feb. 14. Sister had typical measles eruption and her case progressed as an average moderately severe case of measles.

Feb. 17. Sister, donor of 10 c.c. blood given intramuscularly to B. H., who on this date showed no signs or symptoms of measles.

Feb. 20. B. H. had typical measles with Koplik's spots and early rash. His case was moderate but did not seem to have been in any way aborted. From the time relations it seems highly probable that he was exposed to some other case than his sister. Probably exposure occurred in school.

Early in March both children were out of doors convalescing from whooping cough.

Case 6.—M. B., female, aged 2.

Feb. 12. Patient has had whooping cough for six weeks. When seen on this date had a definite broncho-pneumonia and was moderately sick. Half sister, E. J., had slight generalized eruption but no Koplik's spots.

Feb. 13. Koplik's spots present in mouth of sister, E. J. Prodromal rash gone.

Feb. 14. E. J. No rash present but there is an increasing cough and coryza.

Feb. 15. E. J. Cough very severe. Rash appeared and rapidly spread over the entire body.

Feb. 17. E. J., donor, 10 c.c. blood. Donor had no fever but presented an otitis media of mild type. Eight c.c. blood given intramuscularly to M. B., who continued to have scattered patches of broncho-pneumonia for several weeks with associated whooping cough paroxysms.

Mar. 3. M. B. presents scant rash on face.

Mar. 4. M. B. shows rash all over body. No Koplik's spots made out. No increase in catarrhal phase or temperature rise above that accompanying the pneumonia.

M. B. gradually recovered from her pneumonia and cannot be said to have been made appreciably worse by her mild measles.

Case 7.—R. K., female, aged 5. In school till March 13. No definitely known exposures to measles.

Mar. 13. Exposed to brother, J. K., who had "cold" and Koplik's spots but no rash. He ran the course of moderately severe measles.

Mar. 14. M. K., aged 13, older brother, in good health, who had measles at the age of five, was donor of 30 c.c. blood given subcutaneously to R. K.

Mar. 26. R. K. presented ten to twelve isolated macular lesions on trunk.

Mar. 27. The eruption consisted of 30 to 40 lesions on face and body. No Koplik's spots, no fever, no cough or coryza.

Mar. 28. Rash has entirely disappeared.

Case 8.—B. G., female, aged one year. Perfectly well.

Feb. 2. B. G. exposed to measles by sister, M. G., who presented early eruption and Koplik's spots on this date.

Feb. 8. M. G., donor of 2.5 c.c. blood, injected intramuscularly into B. G. More blood could not be secured.

Feb. 14. B. G. had typical measles eruption and questionable Koplik's spots but was not very sick. She did not cough as hard as her sister. She remained quietly in bed for one day, but was up and about the rest of the time. Mother said, "She was not as sick as sister."

Apr. 15. Both children now entirely well.

Both children passed directly from measles into typical attacks of whooping cough.

Case 9.—M. R., female, two and a half years old. Well. Never known to have had measles.

Mar. 8. Exposed to sister, H. R., who had fever, coryza, Koplik's spots, cough and moderate eruption on face and trunk when seen this date.

Mar. 9. Mother, N. R., aged 32, donor 15 c.c. blood injected intramuscularly into M. R. The mother, who was perfectly well, had had measles when 10 years of age.

Mar. 18. M. R. wanted to be held.

Mar. 19. Played all day. No symptoms.

Mar. 20. Vomited in the evening.

Mar. 21. Presented scant rash on face, a few Koplik's spots and moderate rash on trunk when seen. She had no fever, no cough, no coryza at any time. Slept well. Appetite unimpaired.

Mar. 22. Rash gone. Child normal in every way.

Case 10.—Harriet R., female, aged six and a half years. In school up to March 8. Cases 9 and 10 are sisters.

Mar. 8. Exposure same as Case 9.

Mar. 9. Mother donor of 15 c.c. blood given intramuscularly to Harriet R.

Apr. 15. Up to this time Harriet R. presented nothing abnormal. No suggestion of measles at any time.

Case 11.—Robert B., male, aged 20 months. Had slight cold. Exposed to sister, Ruth B., aged 3.

Mar. 16. Ruth B. had coryza and conjunctivitis.

Mar. 19. Ruth B. had Koplik's spots and early maculopapular rash on face and trunk.

Mar. 20. Mother, donor, aged 27, had measles at age of seven. Thirty c.c. blood injected subcutaneously. Mother was perfectly well.

Mar. 29. Robert B. slightly "fussy." Nose running. Cough.

Mar. 30. Robert B. coughing harder. No Koplik's spots.

Mar. 31. Robert B. has typical measles rash.

Case ran course of average mild measles.

Case 12.—J. L., female, aged 5. Perfectly well.

Mar. 15. Brother seen with typical measles. Koplik's spots, rash on face and body in early stage.

Mar. 16. Mother, aged 24, perfectly well, donor of 30 c.c. blood injected subcutaneously into J. L. Mother known to have had measles in childhood.

Mar. 24. J. L., cough and sneezing this date for the first time. Was slightly "peppless" the day before. Eruption on face. No Koplik's spots made out. Slightly feverish.

Mar. 27. J. L. ran course of moderate measles without particular discomfort. Mother commented, "She did not have nearly as much cough as brother."

Case 13.—B. F., male, aged 1.5 years. Suffering from whooping cough of about five weeks' duration.

Feb. 24. B. F. exposed to baby in neighboring family who developed measles. Exposure was in catarrhal phase of what proved to be typical measles.

Mar. 3. Uncle, aged 14, in good health, donor of 30 c.c. blood. He had had measles at age of 7. Fifteen c.c. blood injected into B. F. intramuscularly.

Apr. 1. Nothing suggesting measles has developed up to this time.

Case 14.—E. F., male, aged 4 years. Has whooping cough.

Feb. 24. Exposure same as Case 13.

Mar. 3. E. F. injected with 15 c.c. blood from same donor as Case 13.

Apr. 1. Nothing suggesting measles has developed up to this date.

Case 15.—S. G., male, aged 18 months, had suffered from repeated upper respiratory infections.

Apr. 7-12. S. G. exposed to brother, W. G., throughout course of typical measles.

Apr. 12. W. G., aged 7, donor of 10 c.c. blood injected subcutaneously into S. G. Donor's temperature was normal and there were no complications of his measles.

May 1. No evidence suggesting the possibility of measles has occurred.

Case 16.—D. M., male, aged 2. Recovering from whooping cough.

Apr. 5. Brother, F. M., seen with typical measles in early eruption stage.

Apr. 5. Mother, aged 33, in good health, donor of 30 c.c. blood given D. M. intramuscularly. The mother had had measles in childhood.

Apr. 14. D. M. a little fretful during night.

Apr. 15. D. M. has scant rash but no coryza. He has an occasional coughing spell of the type noted during earlier weeks of whooping cough. Mother's comment: "It was a very mild case. You wouldn't have known it to be measles if it had not been for the rash."

Case 17.—M. K., aged 2 years, female. This patient was released from scarlet fever but a week before this exposure to measles. She had otitis media as a complication of her scarlet fever.

Apr. 14-18. A. K., aged 16. Brother had the catarrhal and early eruptive stages of measles, exposing M. K. and L. K. (Case 18).

Apr. 20. A. K., temperature 99. Still coughing quite hard. Donor of 25 c.c. blood. Twelve and a half c.c. injected subcutaneously into M. K.

Apr. 28. M. K. presents twenty to thirty scattered lesions on face and back. These are macules of type seen in early measles. No Koplik's spots. No enanthem. Temperature 100.8-R. For several days has had a very slight coryza. No cough at any time.

Apr. 29. Rash increased slightly for twenty-four hours from onset, then disappeared.

Mother said, "She does not act as though she was sick at all."

Case 18.—L. K., male, aged 8. Perfectly well. Cases 17 and 18 are brother and sister.

Apr. 14-18. Same exposure as Case 17.

Apr. 20. L. K. received 12.5 c.c. blood subcutaneously from A. K.

Apr. 26. L. K. slightly nauseated.

Apr. 28. L. K. temperature 102.5. Throat red. Distinct enanthem. Typical salmon colored maculo-papular eruption on face and body, confluent on face. No cough, conjunctivitis or coryza. He said: "I don't feel sick a bit." Up and about, playing.

Cases 17 and 18 reported to be quite normal by the 30th of the month.

COMMENT

The number of cases here presented is small, and there exists marked dissimilarity among them in some essentials for comparison. The conclusions are drawn with a full appreciation of the fact that further study may alter them.

In considering the results let us bear in mind that it is rare for young children, who have not had measles, when exposed under conditions existing in the average home, to be spared from infection.

On the average, measles presents a fairly characteristic picture—with the respiratory disturbance of far greater importance than the eruption, or most phases of the systemic involvement. It is with the respiratory tract infection that most of the unfortunate complications are associated.

A majority of workers feel that the lasting immunity from the mild attack of the disease is preferable to prevention, which will probably be followed by a subsequent attack of the disease on later exposure.

Measles with very mild or absent catarrhal phase must be looked upon as a fortunate circumstance, but avoidance of the infection till some later period in the individual's life, a situation in some cases to be desired.

CONCLUSIONS

1. Whole blood from persons convalescent from measles is available to the physician in private practice in many instances where it is desired to prevent or modify measles after exposure of non-immunes.

2. Non-immunes may be temporarily protected against measles by use of proper amount of blood injected early in the incubation period following exposure.

3. Twenty to 30 c.c. of blood from an individual recently convalescent from measles, injected into the non-immune prior to the eighth day after first exposure, is a good working basis for further study of this problem.

4. When prevention is not secured, modifications resulting are distinctly to the patient's advantage. Mild measles has the advantage of conferring permanent immunity in all probability.

5. When blood from recent cases cannot be secured, that from individuals having had the infection at a more remote time should be used in somewhat larger doses.

6. With reasonable care in selecting donors and in carrying out the technic, the procedure is without danger to donors or recipients.

7. The method described is so simple that it can be utilized by any physician caring for measles cases in his private practice.

BACILLUS ACIDOPHILUS THERAPY

Through the use of bacillus acidophilus cultures a transformation of the intestinal flora of man from a proteolytic to an aciduric type can generally be induced. In cases of constipation beneficial effects in the direction of more ready defecations are said to arise. *Bacillus acidophilus* milk has attained the dignity of tentative recognition by the Council on Pharmacy and Chemistry, though this must not be interpreted as a recommendation for the use of the product. Bearing on the question of how bacillus acidophilus milk acts, experiments have been made which indicate that the action is a strictly bacteriological one, and not physical or chemical. It was found that bacillus acidophilus milk from which the bacteria have been removed was practically without effect in its influence on constipation. Regular bacillus acidophilus milk ingested subsequently resulted in an increase in the number of defecations.—*Jour. A. M. A., May 24, 1924, p. 1696.*

THE VALUE OF PROCTOLOGY IN GENERAL PRACTICE*

LOUIS A. BUIE, M.D.,
Section on Medicine, Mayo Clinic
Rochester, Minnesota

It is desirable that practitioners of medicine and surgery should have sufficient knowledge of the common rectal and anal diseases to insure against error in the diagnosis and treatment of such diseases, just as they make it a practice to learn something of the various special diseases, such as of the eye, ear, nose and throat, and of the gastro-intestinal and genito-urinary tracts.

In proctology the technic of examination of the lowest segment of the bowel is simple, and the necessary equipment small. An anoscope, a proctoscope, an inflating bulb, and an electric equipment are required, and every practitioner should familiarize himself with their use. The principles involved in rectal examinations are not difficult, and with very little experience it is possible to examine the bowel up to the sigmoid. The value of this work can be partly appreciated when it is realized that more than 85 per cent of the symptoms referable to this region can be accounted for by pathologic conditions within three inches of the anal orifice.

One need not become experienced in making differential diagnoses of the more obscure conditions found in the bowel. If just enough were learned about the characteristics of a normal rectal mucous membrane to examine above hemorrhoids in order to determine the presence of a cancer before hemorrhoidectomy, a decided step forward would be made.

There are many types of ulcers which affect the rectal mucosa. It will not be possible here to demonstrate their different diagnostic characteristics, but there is one characteristic common to all ulcerations of the bowel: the bleeding of the mucosa when traumatized. Amebic ulcers, tuberculous ulcers, all types from a hyperemia and simple catarrhal or granular proctitis to the most extensive ulcers, will bleed when traumatized. If one is in doubt with regard to the diagnosis, the presence or absence of a lesion may be determined by inserting the anoscope or proctoscope, and rubbing the mucous membrane of the surface of the bowel with a

*Read before the Southern Minnesota Medical Association, Mankato, May, 1924.

cotton swab. A normal mucous membrane will not bleed after such slight trauma.

Malignant ulcers present a characteristic appearance. They are usually single, and the adjacent mucous membrane is not involved, whereas with inflammatory ulcers there is a more advanced involvement of the wall of the bowel, and the tissues adjacent show an inflammatory reaction. In cases of suspected malignancy, specimens for biopsy should not be taken until the day before the proposed operation, since the removal of specimens stimulates the growth of the lesion and hastens metastasis.

In diagnosing high rectal lesions the colon-ray is of inestimable value. Such conditions as carcinoma, diverticulitis, ulcerative colitis, spasm, and stricture can easily be detected in this manner.

Hemorrhoids are the most common of rectal lesions, and may cause many symptoms. This is so true that when a patient consults us, instead of complaining of bleeding, pain, constipation, diarrhea, or any other bowel symptom, he will say, "Doctor, I am suffering with piles." Only too often the doctor agrees with the patient without making an examination. He prescribes a dose of salts and a palliative salve or an ointment for piles, and the patient goes away glad that the doctor did not examine his rectum, and the doctor is satisfied because he did not have to do the disagreeable job.

Statistics based on almost 2,000 cases reveal the fact that 18 per cent of patients who have rectal and sigmoid cancers have been treated or operated on for piles during the period of their symptoms. So, when a patient comes in with the familiar expression: "Doctor, I have the piles", it behooves us to give this patient a fair chance for his life instead of procrastinating and allowing a possibly operable cancer to become inoperable. If we do not find malignancy, we may operate on the hemorrhoids. Any operation which is done carefully will correct this condition. The chief trouble in hemorrhoidal surgery is not the character of the operation, but the fact that there is usually no postoperative treatment. The rectum should be treated after a hemorrhoidectomy in the same manner that any infected wound is treated. The patient's bowels should remain quiet for four days after the operation. It is not necessary to use opiates to "confine" the bowel. The patient will see to it that the bowels do not move. On the fourth night an ounce of mineral oil should be given, and again the follow-

ing morning; after that enough oil should be given to produce one soft stool a day. After each defecation for the following two weeks the bowels should be irrigated with hot water (110° F.), until the water returns clear. Irrigating the wound with a mild medicated solution is very helpful and assists healing.

I would make a plea for more consideration of patients who have rectal complaints, and for the elimination of the physician's antipathy to the examination of the rectum. If a patient says he has piles, he should be examined to see what he means by piles; he may mean anything from constipation to cancer.

DISCUSSION

DR. W. A. FANSLER, Minneapolis: I feel that we are very much indebted to Dr. Buie for calling our attention to the necessity of rectal examinations and wish to congratulate him upon his excellent paper. I most heartily agree with him that it is little short of criminal to supply a patient with some palliative medication without examining him. Rectal examinations are relatively simple. A Kelly proctoscope costing two or three dollars, a pocket flashlight or good sunlight and the patient in knee-chest position is all that is needed for adequate examination of most cases. Expensive electrically lighted pneumatic proctoscopes are not essential to good work. A simple Kelly tube and the vacuum produced by the knee-chest position does the rest. The sooner the general practitioner begins to make rectal examinations as a routine the sooner will we quit having 20 per cent of the cases of rectal cancer report recent operation for hemorrhoids.

"Patent Medicine" Secrecy.—For years the medical profession has insisted that the real reason that nostrum makers keep the composition of their products secret is (1) for the glamour that such secrecy throws around them, and (2) the fact that so long as the public does not know what is in a preparation the advertiser's imagination is given freer play. The "patent medicine" makers, on the other hand, have maintained that their reason for keeping the composition of their products secret is that the formula is personal property, and, if made known, the market would be flooded with imitations. Recently, however, Standard Remedies, the mouthpiece of the "patent medicine" interests, has admitted that the medical profession was right and the "patent medicine" makers wrong. It stated editorially: "It should be remembered that while a developed formula has a great value, it is the trade name, the advertising, the merchandising skill applied in connection with it that creates its valuable good-will. Ten to one a thorough search through books of formulæ will reveal that your own is already known to the medical world. But no one can get the same benefit from it that you have gained unless they spend in merchandising it the same money that you have spent." (Jour. A. M. A., Nov. 11, 1922, p. 1692.)

DIET AND REST IN THE TREATMENT OF CARDIO-VASCULAR DISEASE*

J. E. CREWE, M.D.
Rochester, Minn.

Much is being written in these days about the chemical balance that is required in the body to maintain health. There must be an alkaline reserve. This is maintained automatically by the kidneys, which eliminate the excess of acid. The urine acidity should not be more than twice that of the body, but it is frequently 100 times that of the body and frequently 1,000 times as acid as the body.† In many of the modern diseases there is a lowering of the alkaline reserve and a condition occurs which we call acidosis, which is the same thing. Why do we hear so much about acidosis, and why is chemical balance lacking in the body? The answer is simple and is comparable to the reason why farmers have poorer crops and more plant disease as they take more and more crops off the soil without replenishing the soil. Virgin upland soil for the most part is alkaline in reaction and crops at first are luxurious and little subject to disease. As repeated crops are taken off they take with them considerable amounts of the bases, lime, phosphorus, soda, magnesia, etc., and the soils become acid, and spindly crops and parasites and disease result.

The same is true in the body. The bases are removed by the modern methods of preparing food and the alkaline reserve is diminished, and we have weaker growth and more disease.

In view of the high urine acidities as mentioned in Doctor Sansum's paper, alluded to above, one might hazard the problematical thought that perhaps in some instances nephritis might be caused by the irritation due to the high acidity of the urine. Experimental work in animals along this line might show some interesting results.

It is believed that excellent and fairly lasting results can be obtained in the diseases mentioned in the title of this paper for the reasons mentioned later. When the alkaline reserve is lowered there is less resistance to infection, which is one of the factors in the cause of these diseases.

The method of treatment outlined below has been

used practically exclusively in the treatment of cardio-vascular disease at the Cascade Sanitarium at Rochester, Minnesota, during the past seven years and a few cases were treated in this manner during the six years preceding that. The classes of cases mentioned include hypertension and diseases of the heart and nephritis. The classification has been somewhat difficult because of frequent association of cardiac disease and nephritis with arteriosclerosis. All cases of hypertension, whether or not associated with heart and kidney involvement, have been classified as arteriosclerosis and the number of cases treated at the Sanitarium during the past seven years was 104 in number. There were eleven heart cases and fifty-six of nephritis. The series of cases mentioned in this paper, while small, deserves consideration from the fact that the method was consistently followed. This does not include numerous other patients who came for other causes and who had slight hypertension or slight cardiac or kidney involvement. Nor does it include numerous other cases with hypotension. With the exception of two cases treated ten and twelve years ago, no mention is made of the cases treated outside of the Sanitarium previous to its establishment seven years ago. Many of the cases were of the severest type, having previously exhausted other methods of treatment.

Practically no drugs were used in any of the cases, the treatment consisting almost entirely of complete rest in bed with large quantities of milk and hot baths and hot packs.

This paper is not a statistical record because many of the cases have not been followed up, but the chief interest lies in the fact that the method has been consistently followed and that the results in most instances have been highly satisfactory. In the beginning the treatment was used empirically but an attempt will be made in this paper to show that this method is based on sound scientific principles. It is well known that, in many cases, rest in bed, and practically no other treatment, will result in a lowering of hypertension and a decrease in the edema in heart and kidney cases, but the results are not so lasting and the general improvement is less than by the method under discussion.

The method, although modified, of course, in different individuals, is, in general, as follows: The patients are kept strictly in bed in the position most comfortable, many patients being unable to lie down in bed. Frequently, nothing is given the

*Presented before the annual meeting of the Minnesota Medical Association, St. Paul, October, 1923.

†Sansum, W. D., Blotherwick, R. N., and Smith, Florence: *Jour. A. M. A.*, p. 883, September 15, 1923.

patients except water and oranges for from one to four days. After the preliminary treatment they are put on milk, beginning, as a rule, with from two to four quarts of rich, raw milk daily (Guernsey usually, but sometimes Holstein). This quantity is increased to from four to seven quarts a day. The feedings are one-half hour apart, from seven o'clock in the morning till eight o'clock at night. The bowels are regulated with enemas. Oranges or orange juice is given twice a day and a dish of prunes or figs at night. Some patients prefer a little lettuce at night. No other food is used.

Constipation is a common complication in hypertension and is possibly a factor in the cause of the disease. It is generally supposed that a milk diet is constipating. Experience with milk in large quantities shows that this is not the case. Perhaps a more correct statement would be to say that constipation is generally overcome when this treatment is used for four weeks or more. The reason for these results is believed to be due to the better general nutrition, and it is quite reasonable to believe that the function of the glandular and muscular coats of the stomach and intestines is improved by the better nutrition, and better blood supply that results. This is also favored by the regular use of abdominal massage with a five-pound cannon ball. Constipation does occur sometimes and even impactions of the lower bowel unless precautions are taken. This complication is avoided by the use of a daily enema, which is used in most cases. No bad after-effects have been observed from the use of enemas, and they are discontinued at the end of the treatment. During the past year, excellent results have been had by using a pint or more of acidophilus milk a day.

In extreme cases with great edema, the effects are most interesting and quite regularly obtained. The following case, although an extreme one, illustrates results that can be obtained:

CASE 1. Mr. K. S., South Dakota; age 54, August 1, 1920. This patient was advised to return to his home, and his family informed that he would probably live but a short time. He insisted on entering the Sanitarium, however. His heart was dilated and he had massive edema, having strips four inches wide sewed into his trousers so that he could get his legs into them. His blood pressure was 224 systolic, 138 diastolic. Urine showed no albumin. Specific gravity 1.012. He was very short of breath. Large doses of digitalis and jalap had been taken.

All medication was discontinued. The first two days he had only oranges and water, the third and fourth days oranges and two quarts of milk, three quarts on the fifth

day, and for the next nine days four quarts a day with orange juice; the next ten days five quarts, on the twenty-sixth day six quarts, and four and five quarts a day for the next week. His weight on entering was 240 pounds, on the seventh day it was 214, a loss of twenty-six pounds in seven days. The fourteenth day it was 205, twenty-first day 204, thirtieth day 203 pounds. At the end of the fifth week he weighed 205 pounds, at which time he left for home. Two months later he wrote that he was feeling fine and was working and that he had gained ten pounds of solid tissue, bringing his weight to normal, 215 pounds. His blood pressure reached 160 systolic, 110 diastolic, by the middle of the third week. Systolic pressure remained at 160, the diastolic came down to 104. He left against advice but said he would return if he had any trouble. At the time of his discharge, his urine showed no albumen, specific gravity 1.020. There was no edema visible.

CASE 2. Miss C., living in Rochester, was treated for six weeks by this method twelve years ago. Single woman. Age 55 at that time. Systolic blood pressure was 245. She had intense headaches and dizziness and heart involvement; was unable to lie in prone position or to walk. Has taken three short courses of this treatment since then. One year ago her blood pressure was 170. She adopted and has raised a child since first treated and has almost constantly managed a boarding house since first treated.

CASE 3. Another case, my mother. Age 68 at that time, ten years ago, had a systolic blood pressure of 245 with kidney and heart involvement, retinal hemorrhages and was nearly blind. Received this treatment for six weeks. Has enjoyed very good health since until one year ago, while away visiting, she had a stroke, paralyzing the right hand and arm. She has partially recovered the use of the arm, and her general health is quite good. She reads almost constantly and writes a good deal with her left hand. Has taken short periods of the treatment several times since the first time.

CASE 4. Mr. S., of Missouri. Age 54, June 1917. This patient had an extremely high blood pressure, frequently reaching 300 or more, or as high as the instrument registered. He had kidney and heart involvement and was unable to be out of bed. He also suffered greatly from insomnia. There was complete loss of sight in the left eye and very little vision in the right, due to retinal hemorrhage. He had the usual method of treatment for six weeks. Before returning home, he was able to have a tonsillectomy done. Later, during the war, he was engaged on a grain commission at Washington, and in one letter his wife stated that "he was as well as a man could be," but that he was working at his usual high tension. Later he worked at his business of grain operator. He died one year ago after a strenuous business trip in the East.

CASE 5. One other patient had a systolic blood pressure going above 300. He was greatly improved by treatment and lived nearly two years. He reported shortly after returning home that he had driven fifty miles to attend a dinner.

CASE 6. Mrs. L., Kentucky. Age 65, January 1921. This patient complained of constant headaches, and dizziness, loss of strength and great anxiety about her condition.

Urine normal, heart fairly good but at times too fast. Blood pressure, 238 systolic and 110 diastolic. Weight 121. Treatment begun in the usual way, taking four quarts of Guernsey milk on the third day and from four to seven quarts daily after that for seven weeks. During this time she gained twenty-four pounds, when she left. On discharge her blood pressure was 150 systolic, 90 diastolic. From a recent report this patient had retained her weight and was quite well.

CASE 7. Mrs. A., Kentucky. Age 60, March 1922. Weight 112. Systolic pressure 160, diastolic 100. Time of treatment, twenty-six days. This patient gained sixteen pounds in twenty-six days. Hemoglobin rose from 64 to 32. At a recent report she was quite well.

CASE 8. Mrs. S., South Dakota. Age 51, March 1918. This patient had usual symptoms of hypertension, headaches, etc. Albumen present. Systolic blood pressure 226, diastolic 130. This patient took five and six quarts daily for thirty-four days. Systolic pressure on seventh day was 150, diastolic 110. At time of discharge the systolic pressure was 132, diastolic 86. The patient was greatly improved in every way. In March 1922 she returned. She had just lost her favorite son and was emotional. Systolic pressure was 220, diastolic 110. She remained five weeks, taking only three quarts of milk a day, as she had increased in weight and did not want to gain. At the time of her discharge she had lost six pounds in weight and the systolic pressure was reduced from 220 to 150, diastolic from 110 to 96.

On account of space only one heart case will be reported.

Mrs. H., Rochester. Age 66. This patient had marked dilatation with massive edema. Weight 174. And was unable to walk. She had exhausted the usual drugs. Pulse 130. Systolic blood pressure 120. The diet was two oranges and three to four quarts of milk a day. The edema was rapidly reduced but the patient was not weighed again until her discharge at the end of five weeks, when she weighed 153 pounds, a loss of twenty-one pounds. Pulse at the time of discharge was 100 and regular, condition of heart and general condition greatly improved. The following winter she had a very severe attack of facial erysipelas, but recovered and was able to do part of her housework until February of this year, when she had an attack of pneumonia and died.

Two nephritis cases died in the hospital. One had a beginning coma on admission and the other practically an anuria, and died in three days. Autopsy showed practically no kidney substance remaining.

During these years there were a number of interesting cases, having hypotension. The same treatment gives marked results in these cases. Briefly the following reports will show the rapid improvement:

CASE 9. Mrs. R., age 39, weight 89.5 pounds. Systolic pressure 84, diastolic 60. On the fourteenth day the systolic pressure was 110, diastolic 70. Four and one-half pounds increase in weight.

CASE 10. Mr. D., Kentucky. Age 33, weight 120. Systolic pressure 84, diastolic 58. At the end of two weeks weight increased ten pounds, systolic pressure 120, diastolic 72. Many other similar illustrations could be given.

The good results in this series can be attributed to the following reasons:

1. Rest—thus avoiding all waste and strain.
2. Abundant or even hypernutrition with a food that has the following advantages: (a) is easily digested; (b) contains all the elements necessary to life and growth; (c) is raw, the chemical and vitamin properties unaltered by heat or by storage; (d) freshness; (e) a food that is rich in phosphates and lime, potash, sodium and chlorine, etc.
3. The large fluid intake which is tolerated and has the advantage of diluting the toxins and washing the tissues.
4. The baths and packs, increasing the elimination by the skin and thus saving the kidneys.
5. The probability that the alkaline reserve is increased as shown by the fact that the urine is frequently alkaline after the patients have been on this diet for a few days.

The advantage of the treatment is that it is intensive. Lasting results can be obtained in a comparatively short time and can be made fairly permanent by repeating the treatment at least yearly and by adhering to the diet prescribed and using one or more quarts of milk daily.

Practically any patient can take milk in large quantities. Of all classes of patients treated, less than 2 per cent could not drink milk in quantity.

At the completion of the period of treatment the patients are given careful instructions regarding hygiene and diet. They have been advised to drink one or more quarts of fresh milk a day. (One patient lived exclusively on milk for more than two years.) They are also advised to eat more of the following foods than they have been accustomed to use: more fruit, especially oranges; more green foods including lettuce, raw cabbage, sauer kraut, and the coarser vegetables that can be eaten raw. They are allowed a small amount of fat meat, fish, etc., two or three times a week, especially advised to select sweetbreads, liver, tripe, etc., avoiding muscle meats. They are advised not to overeat. In addition they are advised to follow suggestions made in the paper, "Factors in Longevity."*

Dr. Sansum's excellent article, mentioned on the

*J. E. Crewe, M.D.: Factors in Longevity. Minn. Med., Oct., 1922, p. 600.

first page of this paper, bears out the advisability of the diet mentioned.

DISCUSSION

DR. JOHN H. MOORE: When I first heard of this method of treating cardio-vascular disease by putting the patients to bed and filling them as full of milk as Dr. Crewe says he does, it seemed almost incredible that a human being could hold that much fluid in as short a period of time as one day. I have tried this thing out myself in the last two years, and while I never succeeded in getting patients to take eight or nine quarts a day, I have gotten some of them to five quarts a day and held them there several days.

I am sorry that Dr. Crewe did not mention one or two things which I think are very important in his method of treatment. It sounds perfectly simple to tell a patient to go home and drink milk. You try it and you find it cannot be done. I know of nothing in the practise of medicine that requires greater care than the treatment of cardio-vascular cases such as Dr. Crewe describes. Constant supervision is the thing, if anything, that will insure success. We know that those patients for whom we prescribe rest and who go to bed will frequently improve without anything else being done for them, but I do believe there is something of value along the lines of what Dr. Crewe in another paper calls hypernutrition and hyperelimination. These patients come in and usually complain of headaches and various subjective symptoms, and it is really surprising how in a few days they will become comfortable.

I have found that where I have had failures in this work has been in the cases where I simply told them how much milk to take and told them a few things as to taking care of themselves and sent them home. They need constant supervision. During the first few days under treatment you will find that the systolic blood pressure will drop rather rapidly, the diastolic not dropping as rapidly, and then towards the end of the first week in treatment the systolic blood pressure will rise again, and as treatment is continued it will gradually settle down to a new low level in favorable cases. I have been unable to account for the rise of the systolic blood pressure towards the end of the first week, and I would like to ask Dr. Crewe if he has experienced that rather characteristic rise. I enjoyed his paper very much.

DR. J. E. CREWE: A study of the lives of aboriginal people shows much of interest in their simpler methods of living. We have probably all marvelled at the wonderful physiques of the people we sometimes see in the movies when they show examples of savage and semi-savage people. These folk live on simple food and are very robust and have little disease for the most part.

Charles Darwin during his trip in South America, many years ago, marveled at the Fuegians, whom he saw near the Straits of Magellan. These were very robust people, averaging more than six feet in height, who were able to undergo great hardships. They lived on shellfish and certain fungi which grew there, and their diet was extremely simple. He also spoke of the people in the western part of Argentina, who lived almost exclusively on a meat diet, averaging about five pounds a day apiece. He states that they were a very hardy and robust people. The Eskimo,

before they were contaminated by white people, had little disease and were robust and lived on a diet consisting almost exclusively of meat and fish.

One can find many wonderful things in some of the old books that we no longer read.

For instance, you remember how Stanley, when he went to rescue Emin Pasha, took five or six hundred negroes from the western coast of Africa, traveling along the Congo through swamp and jungle in a tropical climate. These natives carried from forty to eighty pounds apiece, and he had to obtain their subsistence from what he found on the way. These men were well and contented when they had an abundance of simple foods, such as bananas and cassava. The only difficulties they had were when they were unable to obtain any food, at which times they became sick and had ulcers and intestinal trouble, and many died.

There are many interesting things to be found in books of travel and those written by explorers. These observations should teach us that health is dependent to a large degree on food, and that it is not necessary to have large varieties of food but that it must be fairly abundant and simple, and not "tampered" with as our modern civilized food is.

Colonel McCarristan's experiences while resident for nine years in Northern India are of great interest and very important. Many observations of modern men point to the same thing.

Milk offers a convenient method of overcoming some of the deficiencies of our modern diet, but it is quite likely that results can be obtained by other methods such as recommended by Dr. Sansum and others.

The Commercial Taint in Medical Advertising.—The advertisements of firms that sell apparatus, especially for physiotherapeutics and diagnostic uses, show a tendency to stress the idea that the purchaser of such apparatus will increase his income by impressing the layman with the scientific attainments of the individual who uses it. No decent man in the medical profession thinks of adding to his armamentarium for the purpose of financial gain. An advertiser's appeal to buy a piece of apparatus because of the "psychic effect" which it may produce on the patient is repugnant and insulting. Any firm that thinks it is going to obtain the good will of the medical profession by an appeal to the sordid is sadly mistaken (*Jour. A. M. A.*, July 5, 1924, p. 44).

Cellasin.—Cellasin is sold by the Cellasin Company, Buffalo. Cellasin, then marketed by another firm, was reported on by the Council on Pharmacy and Chemistry about fifteen years ago. It was submitted to the Council with the claim that it was a ferment absorbed unchanged into the tissues, that it cured diabetes mellitus and that it cured tuberculosis and established immunity against this disease. The Council's report at that time brought out that the claims were unwarranted and that it contained, not a ferment, but a spore-producing bacterium which splits sucrose largely into lactic acid (*Jour. A. M. A.*, July 5, 1924, p. 58).

THE COSTO-CHONDRAL GRAFT FOR THE REPAIR OF SKULL DEFECTS*

ADOLPH M. HANSON, M.D.

Faribault, Minn.

Skull defects may be classified as: large or small; pulsating or non-pulsating; frontal, parietal, occipital, and defects of the upper vault. Skull defects requiring graft for repair are usually the result of injuries to the skull and operations made necessary thereby.

The indications for skull graft are: (1) defects which pulsate and cause headache, vertigo, nausea and weakness at rest or on exertion; (2) defects that include live areas, causing irritative lesions because of edema resulting from a pinching of the brain tissue, the symptoms depending upon the area involved; (3) cosmetic reasons.

Let us for a moment consider the existing condition in an old cerebral injury with a pulsating defect over a "live area." For the sake of illustration we may consider a defect over the motor area. Below the defect we have a scarred brain with, perhaps, adherent membranes. If no cyst is present, this healed portion of the brain, on stooping or exertion, is forced into the defect with the following result: a certain amount of edema, more or less, being constantly present, any condition, as epilepsy, spasticity, etc., is aggravated. This is not so noticeable in cases with very small or very large defects, but in those where the defect is large enough to permit of a pinching of the brain tissue, the convexity of the brain tissue when forced into a defect of 3 or 4 cm. by 6 cm. is very marked; whereas, in a large defect the convexity is only slight. The more marked the convexity, the tighter is the pinching process, and the resulting injury and edema of the part involved proportionately greater.

In heterografts, where silver, gold, or celluloid, or any other substance is used, the "man-hole" has simply been given a cover. The defect of the internal table and its space above (5 to 8 mm.) still affords an internal hernia into which the brain may be forced with sufficient force to produce a slight insult sufficient to cause or keep up a slight edema. In this manner, a heterograft may only slightly benefit a chronic localized edema, or not at all. The autograft of costo-chondral cartilage, that is

one-half to two-thirds the thickness of the normal rib, restores the normal thickness of the bony covering and prevents all possibility of pinching. With the internal table restored, a chronic localized cerebral edema will gradually subside.

It was the practice of Shutro in Paris, during the great war, to use thin cartilage grafts, because they were pliable and easily handled, but this has fallen into disrepute because such grafts absorb. The speaker uses a graft from one-half to two-thirds the thickness of the chondral rib. Such grafts do not absorb, but become firmly embedded, affording a dense protective layer that restores the internal table.

Fig. 1. Before operation.

The technique of the operation is briefly as follows: The head is painstakingly shaved and prepared by washing with soap and sterile water; sponged with ethyl alcohol and dried by sponging with ether. The site of choice for securing the graft is over the costo-chondral cartilages of the

*Read before the Southern Minnesota Medical Association, Mankato, May, 1924.

Fig. 2. Skull defect exposed.

Fig. 3. The cutting of the costo-chondral graft.

fifth, sixth and seventh ribs, either side. This is prepared in the same way. Using a one-half per cent novocain solution to which one thirty-second grain of adrenalin chloride has been added per 60 c.c., a block of scalp about the defect is injected; also, a block of skin, including the deeper structures, at the site selected for securing the graft. The old defect is exposed, employing a tripod incision, exposing well beyond the margins of the defect, when possible, carefully separating the galea from the dura. The dura, adherent to the margins of the defect, is freed by the use of a dural separator. The graft is now secured and trimmed to fit the defect. Taking care that the head wound is dry and all clotted blood removed, the defect is carefully sponged with ethyl alcohol and the graft laid on the dura with the smooth uncut surface inward. The scalp is now closed in layers, using interrupted No. 0 or 00 chromic gut sutures in the

galea and interrupted silk sutures in the scalp. A pad of sterile gauze is placed directly over the defect and graft and secured by adhesive strips in such a manner as to keep the graft firmly in place and prevent bulging until it becomes firmly adherent and embedded. This pad is changed and carefully readjusted in three or four days, when the scalp sutures are removed; again one week later; and, again ten days later. At the end of three weeks the graft has usually become firmly embedded and all dressings are removed. In large defects in the parietal or occipital regions, the pad should be kept in place for six weeks.

The following case report with illustrations is submitted:

Case History No. 10621. W. F. O. Age 28 years. Male. Single. White. American.

While driving an automobile on Jefferson Highway near Faribault, Minnesota, on Sept. 20, 1923, drove off the road

Fig. 4. The costo-chondral graft in place.

Fig. 5. The galea sutured.

Fig. 6. Six weeks post-operative.

striking a culvert and was thrown violently against the handle of the windshield wiper. He was found in the automobile bleeding from the forehead, nose and mouth

by a farmer about 6 A. M. No history of accident obtainable from patient.

Diagnosis: Compound, comminuted fracture of the frontal bone, including the right orbit and most of frontal sinus; intra-cranial hemorrhage and severe concussion; fracture of both maxillary bones with displacement and separation from normal articulations.

Treatment: Lumbar puncture, intra-spinal pressure 18 mm. mercury, cerebro-spinal fluid bloody.

Operation, September 20, 1923, at 7:30 A. M. Trepanation of skull with removal of comminuted bone fragments, pieces of windshield and vulcanized rubber, including the mesial half of the right orbit. Sub-temporal decompression right side.

The teeth of the upper and lower jaws were brought into correct articulation and held in place by a four-tailed bandage by Dr. J. A. Hanson, D.D.S. This was carefully readjusted and the articulation inspected twice daily.

The patient's mentality began to clear up on the fourth day post-operative and the patient had an uneventful recovery, leaving on the twentieth day post-operative.

On January 16, 1924, the skull defect was exposed for the purpose of doing a skull-graft, but the remaining portion of the frontal sinus was found to contain fluid, resembling a milky serum. The external wall of the remaining portion of the sinus was removed by rongeurs, the lining of the sinus on the posterior wall removed by a curette and the posterior wall swabbed with phenol. The skin was closed with drainage. The patient was allowed to leave the hospital on the fifth day post-operative.

On February 5, 1924, the skull defect was again exposed and portions of the costo-chondral cartilages of the seventh, sixth and fifth ribs removed for the graft. The sutures were removed on the third day post-operative and the patient permitted to leave the hospital on the eleventh day.

These operations were performed under local anesthesia.

Illustrations of this case are shown as they most clearly demonstrate the technique of this operation.

POISONOUS COSMETICS

Numerous cases of poisoning due to the use of cosmetics containing harmful ingredients are reported in a recent article by Cole in the Journal of the American Medical Association.*

Lead is apparently frequently used in hair dyes, face enamels and cheap face powders and their use has often resulted in severe lead poisoning, in one case with fatal results. Mercury is another dangerous metal sometimes found in hair dyes, but more often in face cream and skin bleaches. The concentration of the mercury compound is frequently far greater than is commonly employed for disinfecting purposes. Bismuth is sometimes used in the preparation of so-called rice powders, the use of which gives rise to clamminess of the skin, nausea and spasms. Arsenic has occasionally been found in hair dye but is presumably not a common ingredient. Wood alcohol was found by one analyst in 33 per cent of the toilet waters exam-

ined. Silver compounds and pyrogalllic acid are frequently used in the manufacture of hair dye and may endanger the patient in the same way as lead or mercury. The metals calcium and barium are largely employed in the manufacture of depilatories and are apt to cause skin eruptions. The same may be said of many of the deodorants used by women.

According to the writer the most dangerous drug of all those used in cosmetics is paraphenyldiamin, which, because of its irritating character, should not be allowed in hair dyes. It causes an intense skin eruption which is persistent, often lasting for weeks. Several deaths are reported as being due to the use of this chemical.

The dangers from the use of cosmetics are of two types—first the mechanical obstruction of the pores of the skin and second, the destructive action of certain harmful ingredients; the amount of harm done depending on the particular chemical used, the duration of its application, the area to which it is applied, and the susceptibility of the person using it.

Medical Mutations

With the recent development of the scientific side of medicine the undergraduate medical course has been lengthened until now a minimum of seven years faces the medical prospect as he leaves high school. And if the academic degree, the desirability of which for the professional man has been and always will be a matter of taste, is first obtained, nine years are necessary before even a license to practice medicine is obtained. It is no wonder that postgraduate courses along special lines have been proportionately short. As medical science develops still more is the medical course to be further lengthened in an endeavor to cram all medical knowledge into the undergraduate's head? Even today it is impossible for the graduate to keep thoroughly abreast of progress in a specialty to say nothing of the whole field of medicine. It is apparent that we are approaching the time, if we have not already reached it, when training in the specialties will have to be more emphasized and the time period required for the M.D. degree kept stationary or even shortened.

This whole subject was very comprehensively presented by Dr. Pusey, president-elect of the American Medical Association, in his recent address* to the House of Delegates. Dr. Pusey suggests that the present seven year requirement be cut to four and a half years, these to consist of three years of medical training and a year and a half at least of internship.

This is a radical proposal and would mean the elimination of much from the present undergraduate curriculum. Undergraduate work includes much that could very profitably be transferred to postgraduate courses and some work that might to advantage be left out entirely. Practice in the art of medicine—that is, the actual performance of things medical—should not be abbreviated. If shortening the undergraduate course will result in a more poorly qualified graduate, such a step should not be taken. No change should be made which will undo the remarkable improvement in medical education brought about since 1900 largely through the work of the Council on Medical Education and Hospitals of the American Medical Association.

Shortening the undergraduate medical course to the extent suggested by Dr. Pusey would attract more young men to the medical profession. Is this necessary or advisable? There is no dearth of applicants for admission to medical schools as far at least as local conditions are concerned. A shorter course, would, however, be of advantage to the poor boy.

There is some room for argument as to whether there is an actual scarcity of physicians today. The various cults, however—chiropractic in particular—are turning out a horde of half educated so-called doctors and a very considerable proportion of the population is patronizing them. In this connection we wish to recall the result of the investigation made by Dean Lyon of the University of Minnesota Medical School, which appeared as an editorial in the February, 1923, number of MINNESOTA MEDICINE. His conclusion was that “in not a single place do we find an osteopath or chiropractor serving the people with no regular physician available” and he makes that point that irregulars “are not taking the place of the doctor but are additional to him.” Whether turning out more physicians would remedy the situation and supply a demand now met by the irregulars is open to question.

It is interesting in this connection to consider the

*Jour. Am. Med. Assn., June 14, 1924, vol. 82, p. 1960.

subject of medical education in England. There are some features of their system of granting degrees which it might be well to imitate although there are certainly others which it would be well to avoid.

The lowest degree entitling a physician to practice in Great Britain is the L.S.A. (Licentiate of the Society of Apothecaries). The next degree in order is the L.R.C.P., M.R.C.S. (Licentiate of the Royal College of Physicians and Member of the Royal College of Surgeons). This is known as the "conjoined degree." Examinations are held each three months and the subjects are divided into three groups—medicine, surgery, and gynecology and obstetrics.

For the doctor who elects to devote his attention along medical lines, examination is taken for the M.R.C.P. (Member of the Royal College of Physicians). This is the highest degree obtainable by examination and indicates special attainment. The degree of F.R.C.P. (Fellow of the Royal College of Physicians) is purely honorary and is granted for outstanding achievement in the medical field.

If surgery is elected, examination for the degree of F.R.C.S. (Fellow of the Royal College of Surgeons) may be taken. This is a most rigid examination covering anatomy, physiology and surgery and the degree means something.

The degrees of M.B. (Bachelor of Medicine) and M.D. (Doctor of Medicine) are granted in England and rank higher than the conjoined degree but frequently are not possessed by those having the degree of F.R.C.S.

In England the time element spent in study does not figure as prominently as in our country. Examination is all-important. The undesirable feature of cramming is therefore more in evidence.

Our titles of F.A.C.S. and F.A.C.P. are direct imitations of the British degrees. The rapidity with which our titles have been granted in an apparent effort to catch up with our English cousins has distinctly detracted from the standing of the titles and yet the move is generally admitted to be in the right direction.

The desirability of establishing degrees for postgraduate work which will signify special attainments is becoming more and more apparent. Such degrees would spur the practitioner on to perfect himself along certain lines and would draw the line of demarcation more clearly between specialist and general practitioner.

The proposition of enacting fundamental changes in medical education in this country is a vital question and is eliciting considerable discussion as a result of Dr. Pusey's address. The problem is, of course, one for medical educators to solve.

Recent Distribution of Physicians in Minnesota

Attention is frequently called to that fact that physicians are congregating in the cities and that the rural districts are consequently suffering from lack of medical attention.

Figures are not at hand showing the distribution of physicians in cities and rural communities in Minnesota. Since the first of the year, however, the medical graduates of the University of Minnesota for the past ten years have been located by Dean Lyon's office. The following table has been drawn up to show the distribution in towns or rural districts of the recent graduates irrespective of whether they located in Minnesota or other states. Comparison is made with the distribution of the population in Minnesota. Possibly the comparison should have been limited to the physicians locating in Minnesota.

	No. of	Percentage	Percentage
Size of city	graduates	of graduates	of total population
Less than 5,000...	164	31	61
5,000 to 50,000...	92	17.5	9
50,000 or over...	239	45.5	30

Population figures have been obtained from the 1920 census and fractions have been omitted. Six per cent of the recent graduates could not be located, had died, etc. A number of graduates are taking postgraduate work in Rochester or are associated with the Mayo Clinic and this accounts for some of the relative high percentage of recent graduates (17.5) in cities of 5,000 to 50,000 population. It is interesting to speculate what percentage of the graduates who are now at Rochester would have sought country locations and thus tended to relieve the dearth of rural physicians, had not Minnesota been possessed of the Rochester clinic.

Specialism is bound to be limited to localities where there are at least several doctors. Patients will ever be referred from the rural districts to the larger centers of population for special medical attention. Rural communities are therefore not entitled to the same ratio of doctors as the towns and cities.

Further, doctors in the towns of 5,000 population

and over care for a certain portion of the rural population in the immediate neighborhood.

It may be reasonably concluded from the above figures that as far at least as Minnesota is concerned there is a tendency for recent graduates to avoid rural locations.

Smallpox

There are few infectious diseases that can be so largely prevented as smallpox. Yet propaganda will probably always have to be maintained in order to keep the population thoroughly vaccinated. While a small percentage of people in this country are opposed to the idea of vaccination against smallpox because of ignorance, prejudice or simply anti turn of mind, most of the lack of immunization is due to neglect.

In a circular recently compiled by Dr. McDaniel, of the Division of Preventable Diseases of the State Board of Health, and sent to the various health officers throughout the state, the smallpox situation in Minnesota is clearly set forth. It seems that a laborer from Canada introduced a malignant strain of the disease into Duluth in January of this year. The infection spread through St. Louis, Carlton, Aitkin and Lake counties and gained a foothold in Wisconsin. Up to August first there had been 193 cases with forty deaths in Minnesota.

Certain points about smallpox should be emphasized.

1. Smallpox in rare instances can be contracted a second time.
2. Smallpox may be contracted in spite of a successful vaccination. It is even possible for smallpox to develop where a successful vaccination has been obtained within seven years although this is rare.
3. The older the vaccination scar the less immunity is present.
4. Smallpox developing in successfully vaccinated individuals is milder than in the unvaccinated. A virulent strain may not lose its malignancy because of mild manifestations in a vaccinated individual.
5. Children as a rule react less severely to vaccination than adults.

Reports of numerous outbreaks of smallpox throughout the country merely emphasize the importance of continually reminding our clientele of the necessity of keeping immune against smallpox.

MISCELLANEOUS

STATE FAIR EXHIBIT

The State Medical Association and the University have for the first time been invited to put on a health exhibit conjointly at the State Fair this month. The joint action is a particularly happy one as the University has the best facilities conceivable for getting up a worthwhile exhibit of this sort, and the collaboration of the physicians of the state assures the proper sort of display. This sort of activity is no new departure for the University. At the Minneapolis Health Exhibit, held in conjunction with the last Minneapolis Clinic Week, the University under the supervision of Dr. W. A. O'Brien did itself proud in the character of its display. The fact that Dr. O'Brien has charge of the State Fair Exhibit assures its success and was a factor in obtaining the appropriation from our Association to cover incidental expenses.

The following excerpt from a letter to Dr. F. J. Savage, chairman of our Public Health Committee, indicates the educational nature of the exhibit:

July 31, 1924.

Dear Dr. Savage:

The final arrangements for our space at the State Fair have been completed. We have been given 60 feet in the lower section on the right side. There will be a large sign placed over the exhibit with the lettering, "University of Minnesota Medical School and Minnesota State Medical Association."

The booths will be divided as follows: One large central booth 16x10 feet. In the front of this exhibit there will be a 10-foot table with demonstration of the circulation of the blood through the web of a frog's foot; a mechanical moving thorax; a turtle's heart beating outside the body in a bell-jar; a small hand model of the action of the diaphragm in breathing, containing a pair of rabbit's lungs in fresh condition. The idea of this exhibit is to convey an impression of the scientific nature of the methods used by physicians in examining patients. In the rear of the booth there will be two large modern manometer blood pressure machines. In the center of the booth at the rear there will be two vital capacity spirometers. Signs calling attention to the value of periodic physical examinations will be placed.

The other booths will be 11x10 feet. In one we will use a display of panels calling attention to the things every layman should know about the early recognition of cancer, as, for example, "a lump in the breast is the chief early sign of cancer," etc. In the front of this booth actual specimens of cancer of the skin, breast, uterus, stomach and rectum will be on display. We will distribute literature provided by the American Society for the Control of Cancer.

The third booth will be used for tuberculosis. In this exhibit we intend to put over the idea that the earlier tuberculosis is detected the greater the chances for arrest. As a background of this exhibit we will use four x-ray shadow boxes showing normal lung and incipient, moderately advanced and advanced tuberculous lungs. Pathologic specimens corresponding with these stages will be placed in front of the shadow boxes on a lower shelf. On either side will be two panels, one showing a chart compiled by the Prudential Life Insurance Company in regard to the probability of cure and, on the other side, placards

advising people to consult their physicians early in regard to any chest trouble.

The fourth booth will be devoted to the things every mother can do for her children at home, that is, assure proper growth and prevent goiter. In the front part of the booth there will be an exhibit of white rats, properly labeled, showing the effects of faulty feeding. In the rear will be a display calling attention to the fact that the water of Minnesota is deficient in iodine and that such deficiency is the cause of goiter. In the center will be a display of the means of prevention of goiter. On the rear wall will be two maps showing the distribution of iodine-deficient water and the percentage of goiter in drafted men.

The fifth booth will be devoted to diphtheria and smallpox. Either a display of methods of growing diphtheria bacilli will be made or the organisms will be shown under the microscope. The propaganda we wish to put over in this section is that every person should be immunized against diphtheria and smallpox.

We are arranging to have a full quota of advanced medical students in charge of the booths at all hours. We trust that these plans will meet with your approval.

Sincerely yours,

WM. A. O'BRIEN.

RESOLUTION ADOPTED BY THE OLMSTED COUNTY MEDICAL SOCIETY, JULY 1924

WHEREAS, vaccination against smallpox and typhoid fever has been attacked by various pseudo-scientific societies and in some instances by the public press as being ineffective in the prevention of these diseases and dangerous to the health of those vaccinated, and

WHEREAS, the experience of the medical department of the United States Army has proved conclusively that, in the case of typhoid fever, vaccination is a safe and dependable measure, responsible for the saving of many thousands of lives during the world war, as is shown by a comparison of the typhoid rate during the Civil War before anti-typhoid vaccination was known, and the rate during the world war, indicating that, had the former rate prevailed, over sixty thousand Americans would have died of the disease instead of the actual number, which was barely two hundred, and

WHEREAS, general neglect of vaccination against smallpox is leading to a greatly increased prevalence, and in some places to its appearance in epidemic and in virulent form, and

WHEREAS, there is positive proof as shown by the records of state and municipal health departments that vaccination with re-vaccination will prevent smallpox, and

WHEREAS, vaccination properly performed and cared for carries no appreciable risk to the health of those vaccinated, as proved by the extensive experience of army surgeons who have treated hundreds of thousands of persons without a death, therefore

BE IT RESOLVED that the members of the Olmsted County Medical Society hereby publicly endorse vaccination as a most effective means for the protection of individual and community health and further that they go on record to the effect that vaccination is a harmless procedure and conducive to public welfare.

OBITUARY

DR. WARREN L. BEEBE

After an illness of seven months, Dr. Warren L. Beebe, well known medical practitioner of St. Cloud, died Wednesday afternoon, August 13, at the Northern Pacific hospital at St. Paul. Dr. Beebe was 76 years of age.

Dr. Beebe was born at Belpre, Washington county, Ohio, March 16, 1848, son of Dr. William and Elizabeth (Rathbone) Beebe. He attended the common schools of his native town and in 1870 was graduated from Marietta college in Marietta, O. From the days of his earlier boyhood it was his determination to follow in the footsteps of his distinguished father. He graduated from the Ohio Medical college at Cincinnati, O., in 1873, with the degree of M.D., a mark of real merit in those days when so many physicians received their training in the office of some general practitioner. Desiring still further to master the profession, Dr. Beebe entered the Bellevue Hospital Medical college, from which institution he was graduated in Centennial year. With this equipment he practiced in his native village under the direction of his father. He also practiced in Barlow in the same state. In 1878 Dr. Beebe came to Minnesota and located in St. Cloud, which city has since been his home.

Dr. Beebe was devoted to his profession, kept abreast of the latest developments in science, chemistry and medicine, and had a reputation as high authority in such matters. His excellent mental powers, his long experience, and his rigid training as well as his upright character and sympathetic nature are among the factors which contributed to his extraordinary success in the treatment of disease and his skill in surgery. Throughout his residence in St. Cloud he was a potent factor in the professional and civic life of the city. He belonged to the Stearns-Benton Medical Society, of which he was one of the founders, to the Minnesota State Medical Association, and to the American Medical Association. In 1890-91 he was president of the state association, and by all of these bodies he has been repeatedly placed in position of honor. He also affiliated with the Masonic body, the Elks and the Knights of Pythias. He was social in his tastes and had a large circle of friends throughout the state. For many years he was local surgeon for the Northern Pacific and Great Northern railways. Politically he several times served the city of St. Cloud as health officer and for a number of years he was United States pension examiner.

Dr. Beebe was married December 28, 1876, to Miss Maria Harte, at Marietta, O., who survives.

DR. H. M. LUFKIN

Dr. H. M. Lufkin, a practicing physician in St. Paul for thirty-seven years, died Sunday morning, July 6, at St. Luke's hospital, following an illness of six months.

Dr. Lufkin was born in Shelbyville, Illinois, in 1860. He was a graduate of the University of Michigan, Illinois State Normal School, Hahnemann Medical College, Philadelphia, and New York City College. Dr. Lufkin was also a student at the New York Polyclinic and in Vienna for two years.

Dr. Lufkin was formerly connected with the staff of the

medical school of the University of Minnesota, president of the Minnesota State Homeopathic Society, a member of the staff of St. Luke's and of St. Joseph's hospitals, St. Paul. At the time of his death he was a member of the staff of the City and County hospital. He was an active member of the Ramsey County and Minnesota State Medical Associations.

Surviving Dr. Lufkin are his widow, two daughters, Bernadine and Anne Virginia; three sons, Hamilton, Nathaniel and Charles Dexter, all of St. Paul; two brothers, Frank N., and Charles D., of Hawaii; a brother and sister, Dudley C., and Charlotte O., of Normal, Illinois.

DR. WALTER COURTNEY

Walter Courtney was born on the east shore of Lake Huron sixty-six years ago. He was of hardy Scotch ancestry and was one of a large family of children. His early training was received in the nearby country schools and in the Canadian forest that bordered the home farm. He was proud of his prowess with an ax. The amount of cordwood that he "got out" during the winter that preceded his matriculation in medical school was one of the exploits of his life.

He was a member of the class of '83 that graduated from the University of Michigan; a classmate of W. J. Mayo and Franklin Mall. He engaged in general practice for a short time, but was made Chief Surgeon of the Northern Pacific Railway in charge of the hospital that was maintained at Brainerd. This institution was one of the first to be maintained exclusively for the care of industrial employees, and was Doctor Courtney's life work.

He was elected President of the Minnesota State Medical Society and served in that capacity for one year. He was given the honorary degree of Master of Arts by his Alma Mater in 1908.

He lived his professional life as a country surgeon, and in that capacity was called upon to treat a great variety of ailments and to meet all emergencies alone. He did his work honestly and well. He was, even after he retired from active practice, greatly interested in medical matters. He was a firm believer in strict medical ethics and the highest professional ideals.

His death, which occurred June 23rd, 1924, has taken from the profession an honored member and from many of us a good friend.

A. W. IDE, M.D.

DR. C. L. GOTHAM

Dr. C. L. Gotham, for several years a member of the staff of the St. Paul Hospital, died Monday, April 28, at his home in St. Paul, following a short illness.

Dr. Gotham was born in 1866 at Weyauwega, Wisconsin. He attended the state normal school at Oshkosh, graduating in 1898. He received his degree as doctor of medicine from Rush Medical College in 1911, following which he served a year's internship at the Swedish Hospital in Minneapolis. In 1916 Dr. Gotham took up his practice in St. Paul, where he continued in practice until the time of his death.

Dr. Gotham is survived by his wife, Della Faulkner Gotham, and daughter, Stella Mae.

REPORTS AND ANNOUNCEMENTS OF SOCIETIES

MINNESOTA STATE MEDICAL ASSOCIATION

The annual meeting of the Minnesota State Medical Association will take place at St. Cloud, Wednesday, Thursday and Friday, October 8, 9 and 10, 1924.

The local committee on arrangements, of which Dr. C. B. Lewis is chairman, is completing arrangements for the entertainment of members of the association at the meeting. Physicians are particularly urged to bring their ladies as entertainment is to be provided. This year the banquet is to be omitted and Thursday evening is to be purely a social affair.

The Council will meet at 10 A. M. and the House of Delegates at 2 P. M., Wednesday, October 8th.

Following are the local committees:

Committee on Exhibits—H. W. Goehrs, Chairman, I. E. Bowling, H. F. Clark.

Committee on General Entertainment—Wm. Friesleben, Chairman, P. E. Stangl, T. N. Fleming.

Committee on Hotel Accommodations—J. H. Beaty, Chairman, J. C. Boehm.

Committee on Entertainment of Ladies—J. P. McDowell, Chairman, C. A. Rathburn.

Committee on Lantern Slides—M. J. Kern, Chairman, C. F. Brigham.

Committee on Reception of Members—W. L. Beebe, Chairman, A. D. Whiting.

Committee on Telephone Service—F. H. Stangl, Chairman, Julius Adams.

Committee on Meeting Places—C. S. Sutton, Chairman, J. S. Dunn.

Sign Committee—H. McGibbin, Chairman, L. P. Adams.

Golf Committee—J. J. Gelz, Chairman.

Officers of the Association are:

President—Archibald MacLaren, M.D., St. Paul.

First Vice President—E. T. Sanderson, M.D., Minneota.

Second Vice President—F. J. Hirschboeck, M.D., Duluth.

Third Vice President—C. W. Bray, M.D., Biwabik.

Secretary—Carl B. Drake, M.D., St. Paul.

Treasurer—F. L. Beckley, M.D., St. Paul.

PRELIMINARY SCIENTIFIC PROGRAM

THURSDAY MORNING—OCTOBER 9TH

MEDICAL SECTION

1. DIFFERENTIAL DIAGNOSIS OF PULMONARY DISEASE—
M. George Milan, M.D., Warren.
2. ARTIFICIAL PNEUMOTHORAX IN ACUTE LUNG ABSCESS—
Everett K. Geer, M.D., St. Paul.
3. LIVER FUNCTIONAL STUDIES IN CLINICAL JAUNDICE—Carl
Hartley Greene, M.D., Rochester.
4. DIABETES IN CHILDREN—
F. W. Schlutz, M.D., Minneapolis.
5. PRACTICAL ELECTROCARDIOGRAPHY—
Harold E. Richardson, M.D., St. Paul.
6. THE ELECTROCARDIOGRAM IN THE MANAGEMENT OF
HEART DISEASE—E. T. F. Richards, M.D., St. Paul.
7. AMEBIASIS—T. B. Tuttle, M.D., Veterans' Bureau.

SURGICAL SECTION

1. THE TREATMENT OF SEVERE INJURIES OF THE SCALP—
Orville N. Meland, M.D., Warren.
2. OBSTRUCTIVE JAUNDICE AND STUDIES IN LIVER FUNCTION—H. Waltman Walters, M.D., Rochester.
3. FOREIGN PROTEINS AS THERAPEUTIC AGENTS IN THE TREATMENT OF ACUTE OCULAR INFLAMMATION—
John F. Fulton, M.D., St. Paul.
4. PREOPERATIVE TREATMENT OF THE PROSTATIC—
Gilbert J. Thomas, M.D., Minneapolis.
5. ACUTE OSTEOMYELITIS IN CHILDREN—
Carl C. Chatterton, M.D., St. Paul.

THURSDAY AFTERNOON—OCTOBER 9TH

GENERAL SESSION

CANCER SYMPOSIUM

1. CARCINOMATA AS SHOWN BY PAPER MODELS RECONSTRUCTED FROM SERIAL SECTION—
Margaret Warwick, M.D., St. Paul.
2. SOME UNUSUAL PATHOLOGIC FEATURES CONCERNING CANCER—Harold Robertson, M.D., Rochester.
3. THE DESTRUCTIVE AND CONSTRUCTIVE SURGERY OF MALIGNANCY—Harry P. Ritchie, M.D., St. Paul.
4. THE RELATIVE VALUE OF SURGERY AND RADIOTHERAPY—
W. J. Mayo, M.D., Rochester.
5. WHAT THE LAITY SHOULD KNOW ABOUT CANCER—
William A. O'Brien, M.D., Minneapolis.

FRIDAY MORNING—OCTOBER 10TH

MEDICAL SECTION

1. HEMORRHAGIC PURPURA—H. Z. Giffin, M.D., Rochester.
2. SOME OBSERVATIONS CONCERNING TIC DOULOUREUX AFTER SIXTEEN YEARS' EXPERIENCE—
Charles R. Ball, M.D., St. Paul.
3. NEWER IDEAS ON THE ROLE OF INFECTIONS IN NERVOUS DISEASE—W. H. Hengstler, M.D., St. Paul.
4. DIATHERMY IN VASCULAR CIRCULATORY DISTURBANCES AND ARTHRITIS—A. E. Flagstad, M.D., St. Paul.
5. CUTANEOUS PICTURE OF LATE SYPHILIS—
Paul A. O'Leary, M.D., Rochester.
6. DISEASES OF THE PANCREAS: DISCUSSION OF THE IMPORTANT SYMPTOMS AND FINDINGS WITH REPORT OF CASES—Moses Barron, M.D., Minneapolis.

SURGICAL SECTION

1. ACCIDENTS IN SINGLE INGUINAL HERNIA—
E. C. Robitshek, M.D., Minneapolis.
2. THE SILENT ANTRUM—
W. L. Burnap, M.D., Fergus Falls.
3. ARTHROPLASTIES—M. S. Henderson, M.D., Rochester.
4. FRACTURES OF THE SPINE—
Emil F. Geist, M.D., Minneapolis.
5. RELATIVE MERITS OF THE DIFFERENT SURGICAL PROCEDURES FOR DUODENAL ULCER—
Donald C. Balfour, M.D., Rochester.
6. TRACING INFECTIONS IN A SURGICAL SERVICE—
Arthur N. Collins, M.D., and Dr. Ritz, Duluth.

FRIDAY AFTERNOON—OCTOBER 10TH

GENERAL SESSION

1. INSTALLATION OF OFFICERS
2. EXPERIMENTAL WORK WITH THE TESTIS—Carl R. Moore, M.D., Chicago
3. CHILD GUIDANCE—
Lawson G. Lowery, M.D., Minneapolis.
4. PREVENTION OF GOITER—O. W. Rowe, M.D., Duluth.
5. DIFFERENTIAL DIAGNOSIS OF PRE-ECLAMPTIC TOXEMIAS AND NEPHRITIC TOXEMIAS OF PREGNANCY—
Albert G. Schulze, M.D., St. Paul.
6. PERIODIC PHYSICAL EXAMINATIONS—
H. W. Cook, M.D., Minneapolis.
7. HEALTH MOVIE

TRI-STATE DISTRICT MEDICAL ASSOCIATION

The annual meeting of the Tri-State District Medical Association, which this year is known as the Inter-State Postgraduate Assembly of America, will take place at Milwaukee, October 27 to 31, inclusive.

The preliminary program appeared in the August issue of MINNESOTA MEDICINE and space does not permit a repetition of the program. The program, which begins daily at 7 A. M. and continues well into the night, includes the names of eminent physicians and surgeons from all over the United States and Canada. Mention a prominent member of the profession and his name is very likely to appear on the program. This association has been growing stupendously because of the remarkable programs arranged. Only the larger cities can afford accommodations for the literally thousands of physicians who attend.

The following is a partial list of distinguished foreign guests who will be present and take part on the program: Professor Theodore Tuffier, Professor of Surgery, Faculty of Medicine, Paris, France.

Mr. A. J. Walton, London, England.

Dr. John Hunter, University of Sydney, Sydney, Australia.

Dr. N. D. Royle, Craginsh, Sydney, Australia.

R. Hamilton Russell, Esq., F.R.C.S., Melbourne, Australia.

Dr. Carrick Hey Robertson, F.R.C.S., Auckland, New Zealand.

Dr. Ralph Worrall, Sydney, Australia.

Dr. H. B. Devine, Melbourne, Australia.

Dr. J. S. Elliott, Wellington, New Zealand.

The banquet will terminate the session and will be addressed by the following distinguished speakers:

Monsieur J. Jusserand, French Ambassador to United States, Washington, D. C.

Sir Arthur William Currie, Vice Chancellor of McGill University, Faculty of Medicine, Montreal, Canada.

Dr. Nicholas Murray Butler, President of Columbia University, New York, N. Y.

Professor Theodore Tuffier, Professor of Surgery, Faculty of Medicine, Paris, France.

Rear Admiral Edward R. Stitt, Surgeon-General of United States Navy, Washington, D. C.

Major General Merritte W. Ireland, Surgeon-General of United States Army, Washington, D. C.

LYMANHURST AND PARKVIEW STAFF MEETING

Owing to the necessity of postponing the regular monthly meeting for August of the Lymanhurst and Parkview staff members, the program announced for the August meeting will be given at the regular meeting to be held at the Lymanhurst School, 1800 Chicago Avenue, Minneapolis, Tuesday evening, September 23, at 7 o'clock.

The following program will be given:

"Review of Chemistry of Tuberculosis," Dr. W. P. Larson.

"Review of Calmet's Recent Work in Tuberculosis," Dr. W. P. Larson.

"Recent Developments in Bacteriology and Serology in Tuberculosis," Dr. Montank.

"The Pathology of Tuberculosis," Dr. Kano Ikeda.

All persons interested in tuberculosis are invited to attend these meetings and participate in the discussions.

NORTHERN MINNESOTA MEDICAL ASSOCIATION

The annual meeting of the Northern Minnesota Medical Association held this year in Duluth, August 4 and 5, was a great success from start to finish. The clinics held each morning were short and snappy and a military precision characterized their management. This prevented any dragging, or napping on the part of the audience. None of the clinics were operative but illustrative cases were presented.

The lunches, one at St. Mary's Hospital given by the hospital, and the other at the Kitchi Gammi Club, tendered by the local profession, were greatly enjoyed. The evening society dinner was addressed by the retiring president, Dr. W. L. Burnap, of Fergus Falls, and Dr. H. Gideon Wells, of Chicago, gave a most interesting address on cancer in its relation to heredity. Those who have heard him speak came away convinced by his experiments and conclusions.

The officers of the association are to be congratulated on the fine program.

OF GENERAL INTEREST

Dr. James B. Vail has disposed of his practice at New York Mills and is now located at Henning.

Dr. A. L. Kusske, formerly of Minneapolis, has moved to New Ulm for the practice of his profession.

Dr. and Mrs. Earl Jamieson, Walnut Grove, returned recently from a motor trip through Yellowstone Park.

Dr. J. A. Cosgriff recently moved from Lamberton to Mankato, where he is to be associated with the Mankato Clinic.

Dr. Milton J. Geyman, formerly of Browerville, will take up a fellowship in Roentgenology at the University of Minnesota this fall.

Dr. Gaius C. Harmon has announced the opening of his office at 2267 Como Avenue West, St. Paul, for the practice of his profession.

Dr. and Mrs. Edward C. Gager, of St. Paul, sailed August 15 from Montreal on the Montclare for Europe, where they will spend a year.

Dr. Wm. A. Meierding, Springfield, with Mrs. Meierding and their two sons, spent the latter part of July touring northern Minnesota.

Dr. C. C. Walker has moved from Raymond to Lamberton, where he was formerly located before taking up his practice at Raymond.

Dr. F. H. K. Schaaf, of Minneapolis, is spending two months in Berlin and Koenigsberg. He expects to return some time in October.

Dr. S. N. Mogilner and family, St. Paul, left July 10th, for a year's stay in Vienna, where Dr. Mogilner plans to take a course in postgraduate study.

Dr. L. H. Fowler, who has been associated with the Mayo Clinic, Rochester, for the past few years, is now located in the Andrus Building, Minneapolis, for the practice of his profession.

Dr. and Mrs. J. S. Shrader, of Springfield, have just returned from a three weeks' tour of the western states, including a trip through Yellowstone and Glacier National Parks.

Dr. Karl C. Wold became associated August 1 with Drs. Larsen, Binger and Wheeler, 1027 Lowry Bldg., St. Paul. Dr. Wold limits his practice to diseases of the eye, ear, nose and throat.

Dr. E. W. Fahey, St. Paul, was elected supreme physician of the Knights of Columbus at the forty-second annual convention held in New York City recently. Dr. Fahey received the election by a plurality of eighty-one votes over his nearest opponent.

At the recent annual meeting of the House of Delegates of the American Medical Association, it was decided to apportion one delegate for each 950 members or fraction thereof. On this basis our State Association is entitled to three delegates at the 1925 meeting.

Dr. and Mrs. Einer W. Johnson, of Bemidji, with their two children, will sail September 4 from Quebec on the Montlaurier for Europe, where they will spend a year. Dr. Johnson plans to engage in the further study of medicine in Edinburgh, London, Vienna and Copenhagen.

Announcement has been made of the engagement of Miss Dorothy Trapp, daughter of Mr. and Mrs. T. J. Trapp, of New Westminster, British Columbia, to Dr. Roger S. Countryman, of St. Paul. The wedding will take place at the home of the bride's parents, Wednesday, September 3.

Notice has been received of the death of Dr. Timothy Geraghty, noted surgeon and authority on urology, which occurred Sunday, August 17, at the Johns Hopkins hospital at Baltimore. Dr. Geraghty was but forty-eight years old. In collaboration with Dr. Rountree, of Rochester, he originated a method for determining functions of the kidneys which now is used throughout the world. For the past ten years, Dr. Geraghty was associate professor of urology in the James Buchanan Brady Urological Institute at Johns Hopkins hospital.

A meeting of the State Board of Health was held at the Capitol in St. Paul August 19th, to which were invited many institution executives for the discussion of the advisability of adopting new regulations for the control of infection both to and from hospitals and similar institutions. As a result of a questionnaire sent out recently by the Board of Health, it became evident that many hospitals have had difficulties in the control of infectious disease among patients, nurses and employees.

It was brought out that there is no state law requiring a hospital to maintain an isolation wing or room. Minneapolis has such an ordinance. Also there is no state law compelling vaccination of school children unless an epidemic exists. The advisability of a law requiring the vaccination of employees in institutions caring for the sick was discussed.

As a result of the meeting Dr. Scofield, president of the State Board of Health, has appointed a committee to draw up regulations to be submitted to the Board of Health and Board of Control for adoption.

The Chicago Eye, Ear, Nose and Throat Postgraduate School announces the following courses:

1. A three months' graded course beginning October 1, January 1, April 1 and July 1, to qualified physicians.
2. A twelve months' graded course beginning January 1, 1925, and every January first thereafter. A three months' course must be taken before entering a twelve months' course.
3. A nine months' course as clinical assistant with salary of \$50.00 a month to those who have had the two above courses, thus completing a two years' course.
4. A clinical course to general practitioners of any duration beginning any time.
5. An operative eye course of one week beginning November 3d.
6. An operative ear, nose and throat course of one week beginning November 10, 1924.

Details may be obtained by applying to the Chicago Eye, Ear, Nose and Throat College, 235 West Washington Street, Chicago, Illinois.

ADVANCES IN THE UNIVERSITY

Reorganization of the department of pediatrics under Dr. Frederic Schlutz has been an outstanding development of the year in the Medical School. Dr. Schlutz comes to the University as a full-time professor, thus settling the status of this department, which had been a matter of some controversy. This arrangement looks forward in part to the time when the Medical School will have the Minnesota Hospital and Home for Crippled Children as a part of its plant, when the gifts of William Henry Eustis shall have been received in full. Results of the interest other donors have taken in the Medical School have come to fruition during the year in the beginning of construction on two hospital additions. These are the Todd Memorial Hospital, for eye, ear, nose, and throat cases, and the George Chase Christian Memorial Cancer Hospital. Both will be connecting units of the Elliott Memorial Hospital. They will be completed about a year hence. Due to this enlargement, Dr. L. B. Baldwin, superintendent of the hospitals, has been put on a full-time basis.

Much more than can be given here must be told of the year's additions to the physical plant of the University of Minnesota and of the development of plans for beautifying the campus. Most of these accomplishments have been the result of plans laid long ago, but just now matured. Among these has been the final removal of the Northern Pacific Railway tracks, leaving quiet and a considerable tract of property where formerly a gully, noisy with the rattle and roar of trains, had to be endured. The athletic Stadium, made possible by the gifts of many thousand loyal friends of the University, is approaching completion. It will be

used for the entire football schedule of the present autumn. The new University of Minnesota library, under construction for two years, is in shape to serve the student this fall, and work has been begun on the Administration Building, a unit in the original Comprehensive Building Program, for which the 1919 legislature voted funds. Other additions to plant that the year has seen placed in service have been the splendid new Experiment Station of the School of Mines, the new Electrical Engineering Building, and a Storehouse and Shops building that houses the many departments for self-service by which the institution is able to make a wholesome saving. Thanks to the care and study bestowed on plans for the Electrical Engineering building by members of the department and by architects, it is said to be the most effective laboratory yet erected for the purpose of collegiate instruction in that swiftly growing field.—Minnesota Chats, Vol. 3, No. 47.

IMPROPER SOLICITATION

Physicians throughout the state and possibly throughout the country recently received two lead pencils from an organization called the National Disabled Soldiers League, New York, with a strong appeal for a contribution of one dollar for the help of the disabled soldiers. The remark in the letter that it was the hope of the writer that no physician would be so mean as to keep the pencils and not contribute the dollar was a clever method of obtaining the desired results in many instances.

A clipping from the Disabled American Veterans Weekly dated Washington, August 15, and issued by General Hines, states in part: "You are advised that this organization does not have any standing before this bureau, and is not recognized in a co-operative relationship as are the American Red Cross, the American Legion, the Disabled American Veterans of the World War, etc. The Bureau would prefer not to comment on the form of solicitation concerning which inquiry is made, as it is at present the subject of investigation."

Further information has been given out by Adjutant Stafford King of the American Legion, Department of Minnesota, to the effect that "So far as I am able to ascertain, the National Disabled Soldiers League is organized for the purpose of securing moneys, and according to my information has no other purpose. It may be legally constituted or not, but in any event the time has not yet arrived in the United States of America when it is necessary to solicit funds for the actually disabled man by any such manner of solicitation. I would suggest that you take the necessary steps to inform your medical associates that this league deserves no constructive assistance."

NEW AND NON-OFFICIAL REMEDIES

The following articles have been accepted by the Council on Pharmacy and Chemistry:

MANHATTAN EYE SALVE COMPANY:

Butyn Ointment-M. E. S. Co.

Holocaine Ointment-M. E. S. Co.

Benzyl fumarate-Abbott. Benzylis fumaras.—It contains not less than 99 per cent of benzyl fumarate. Benzyl fumarate acts like benzyl benzoate and benzyl succinate in lowering the tone of unstriped muscle. Like benzyl succi-

nate, it has the advantage over benzyl benzoate in that, because of its insolubility in water, it is practically tasteless and does not produce gastric disturbance. It is employed in the same conditions as benzyl benzoate and benzyl succinate (see New and Non-official Remedies, 1924, p. 69 and 71). The Abbott Laboratories, Chicago.

Sulpharsphenamine-Metz.—A brand of sulpharsphenamine-N. N. R. For a discussion of the actions, uses and dosage of sulpharsphenamine, see New and Non-official Remedies, 1924, p. 56. Sulpharsphenamine-Metz is supplied in ampules containing, respectively, 0.05, 0.075, 0.1, 0.15, 0.3, 0.45 and 0.6 gm. The H. A. Metz Laboratories, New York (Jour. A. M. A., July 5, 1924, p. 41).

Mead's Cod Liver Oil.—It has a vitamin potency so that one-fourth of one per cent cures experimental rickets in rats in five days when added to the diet. For a discussion of the actions and uses of cod liver oil, see Useful Drugs, 6th edition. Mead Johnson and Co., Evansville, Ind. (Jour. A. M. A., July 12, 1924, p. 121).

Oleo-Bi (Roche).—A suspension of finely divided bismuth oleate in olive oil, containing bismuth oleate equivalent to 0.05 gm. of bismuth (Bi) in each c.c. Oleo-Bi (Roche) is proposed as a means of obtaining the systemic effects of bismuth in the treatment of syphilis (see Bismuth Compounds, New and Non-official Remedies, 1924, p. 74). Two c.c. are administered intramuscularly, preferably into the gluteal muscle, two or three times a week. Oleo-Bi (Roche) is marketed in the form of 2 c.c. ampules. The Hoffmann-LaRoche Chemical Works, New York (Jour. A. M. A., July 19, 1924, p. 195).

Butyn Ointment-M. E. S. Co.—Composed of butyn (see New and Non-official Remedies, 1924, p. 32) 1 per cent, water 1 per cent, wool fat and petrolatum 98 per cent. The ointment is put up in collapsible tubes for application to the eye. Manhattan Eye Salve Co., Louisville, Ky. (Jour. A. M. A., July 26, 1924, p. 271).

PROPAGANDA FOR REFORM

Purifico, a Cancer Cure Fraud.—In 1917 the persons doing business as the Purifico Company pleaded guilty to the charge of the federal authorities that the claim that Purifico was an effective remedy for cancer and other conditions was false and fraudulent. Now a fraud order has been issued against the Purifico Company denying the firm the use of the mails. Analysis showed "Purifico No. 1" to be a watery, alcoholic, sugar mixture of cinchona, plant extractives, a vegetable laxative and potassium iodid. "Purifico No. 2" was a watery, alcoholic mixture of cinchona, plant extractives and potassium iodid. "Purifico No. 3" was a watery, alcoholic, sugar mixture of plant extractives, including valerian (Jour. A. M. A., July 5, 1924, p. 56).

"Cuprase—Chemical Colloidal Copper."—In 1919 the Council on Pharmacy and Chemistry reported on Cuprase, marketed by the Anglo-French Drug Co. It stated that the claims made for this preparation are those commonly made for "cancer 'cures,'" and held that these could not be too strongly condemned. The Council contrasted the loose statement of the Cuprase advertising with the results reported by Richard Weil, who was unable to find that colloidal copper had any therapeutic value. The Council declared the claims made for Cuprase extravagant and cruelly misleading (Jour. A. M. A., July 5, 1924, p. 59).

More Misbranded Nostrums.—The following products

have been the subject of prosecution by the federal authorities charged with the enforcement of the Food and Drugs Act: Smith's Buchu Lithia Pills (C. F. Smith), containing powdered licorice, extracts of plant drugs including uva ursi and podophyllum, sodium, potassium, lithium and magnesium compounds, including nitrate and citrate, and soap. Famous Mineral Well Water (Famous Mineral Wells Water Co.), adulterated water, consisting in whole or in part of filthy and decomposed animal or vegetable substances. Foley's Kidney Pills (Foley and Co.), containing potassium nitrate, methylene blue, hexamethylanamin tetramin and plant material including resin and juniper oil. Ironglad Tonic Tablets (Sanitary Products Co.), containing an iron compound and material of animal origin. Remlock 300 (Remlock Hills Laboratory), consisting of 99 per cent water and 1 per cent calcium hypochlorite, calcium chlorid and calcium carbonate. Trask's Ointment (D. Ransom, Son and Co.), consisting of extracts of plants, including tobacco and lobelia, mixed with fat. Tubbs White Pine Cough Cure (The Tubbs Medicine Co.), consisting essentially of pine tar, extract of a bark, chloroform, sugar, alcohol and water (Jour. A. M. A., July 12, 1924, p. 138).

INDIVIDUAL CONSTITUTION VS. ENDOCRINE GLANDS: Julius Bauer (Buffalo General Hospital Bulletin, Oct., 1923). Those who did not have the opportunity of hearing Dr. Bauer during his visit to the Northwest, have the opportunity of reading his paper in the above noted periodical.

The author first remarks about the tendency to overestimate the important branches of science in the beginning of their development, also the attempts to clear up certain unexplained facts by means of the newly developing science, taking mere hypotheses for established facts.

Eunuchoid gigantism and eunuchoid obesity are two different types of abnormal development, which may be manifestations in primary hypogenitalism. Some other factors must determine the result and the general assumption is that the hypophysis and other ductless glands are the determining factors. If this is the case, how may borderline cases be explained?

The power of growth is a constitutional characteristic, transmissible by inheritance and must be localized in the germ cells. There may be present a high, moderate or a slight constitutional growth-power and as well, varying grades of glandular sufficiency.

The analogy between certain racial and individual peculiarities and the constitutional factor is made. The endocrines do not produce, but rather influence, augmenting or checking the chromosomal potency and not one but the total of all the endocrines combined with the constitutional

chromosomal reactivity of every body cell, determines the consequences of an endocrine trouble and the varied clinical symptomatology.

In conclusion the writer mentions experimental therapy with extracts of fetal organs, which have been seemingly satisfying.

T. A. PEPPARD.

THE MODERN TREATMENT OF TUBERCULOSIS OF BONES AND JOINTS: G. R. Girdlestone (*Tubercle* [London] 1924, v, 32). Twenty years ago tuberculous disease attacking the spine or hip only too commonly meant persistent pain, increasing deformity, sinuses profusely discharging, long months of suffering, lardaceous disease and death. Nowadays there is little excuse for delay in diagnosis or prompt admission to a special hospital. If admitted in good time the patient quickly loses all his pain, ceases to go down hill and starts the slow process of recovery. Although there has been a period of rapid progress, complete uniformity of method has not been secured. The leading special hospitals reflect the ardor of their genius loci whether he worship the sun or the Thomas tradition.

A bone focus is a proof of established tuberculous infection, but it is even more, for the new focus is tangible evidence that the invasion of the body is advancing. Now the enemy has had a great success and has got a new hold. Things are going wrong. It is, however, a fight in which we can join, and treatment has now become so effective that we can insure complete victory for our patient in almost every case. Relapsed cases are the result of lack of sufficient follow-up of discharged patients and disinclination on the part of those responsible to furnish funds for adequate treatment. A cure in our hospital register may be a very sick patient in another hospital's bed.

The aims of the treatment are general and local.

1. First to raise the patient's general vitality as quickly and as fully as possible.
2. Ultimately to restore the full health of the patient, who should be free from any signs of tuberculosis, focal or general, with his powers of resistance to the tubercle bacillus so raised as to enable him to repel any further attack.
3. The prompt elimination of any factor, such as strain or movement, harmful to the diseased part, and the application, so far as possible, of rest, comfort, warmth and stimulus to local circulation.
4. The avoidance of septic infection.
5. The restoration of the strength and function of the affected part.

These points are usually best achieved by prompt admission of the patient to an open-air Orthopedic Hospital. The virtues of sunlight and moving air should not induce us to relinquish the accuracy of our splintage. Operations may be helpful, or even essential to cure, but to consider them as short-cuts is a sin which will be visited on our patients. Rest and time remain the essential ingredients of our prescription.

Food must be adequate but not excessive.

As regards the action of the sun and the wind in tuberculosis, it is most unfair to both to consider them apart.

We want every bit of help we can get for our patients and we now know how to get help from the sun; but I am

not yet convinced that the advantage of pigment is other than protective.

The first step in heliotherapy is the carefully graduated exposure of the body in order to develop pigment; and until and unless pigment is developed, only a small dose can be tolerated, and more than a small dose is definitely harmful.

While the sun warms steadily, the wind cools variably. The sun saves the patient from undue cold, the wind from undue heat. The combination is pleasurable, and like a contrast bath it promotes an active hyperemia in the skin. The wind is itself a great stimulus to metabolism.

Wind and sun are heaven-sent partners, neither can be used to the best without the other. Together they work in ways far beyond direct heliotherapy as a source of health and vigor, they stimulate and cheer us all and particularly patients in open-air wards. Possibly, too, the partnership between sun and air may be more intimate than we know fully yet. One virtue of open-air wards may lie in the effect on our patients of breathing air which is often sunny as well as always fresh.

The splintage should:

- (1) Hold the parts accurately and comfortably in whatever position is chosen.
- (2) Not constrict the circulation in the affected part.
- (3) Not interfere with respiratory movements.
- (4) Allow exposure of the affected part to sun and air and as much exposure of the rest of the body as possible.
- (5) In spinal caries, we should allow full exposure of the back whenever necessary without risk of local strain or movement, and where bone destruction has made a local kyphosis inevitable and desirable for the sake of sound healing and stability, it should be minimized and localized and compensatory curves should be developed.

To open and drain a cold abscess is to commit a surgical crime. Dr. Rollier put the matter thus—he labeled such a proceeding “catastrophic,” and said it was “almost a condemnation to death, not at once, but in two or three years,” and added, “we cannot struggle too much against it.”

In conclusion. A tuberculous focus in a bone or a joint is the obvious part of a deep-rooted disease, serious in itself, crippling if there is delay, disastrous if there is neglect; but it is also evidence of tuberculous infection of the body which pre-existed but is now gaining the upper hand. On the other hand, modern treatment with its artistic use of rest, food and weather, if started in good time and kept up long enough, will almost always bring about a cure.

ARTHUR T. LAIRD.

THE RELATION OF BLOOD PRESSURE TO THE AMOUNT OF RENAL TISSUE: Hilding C. Anderson (*Jour. of Exp. Med.*, May 1, 1924). Dr. Anderson presents his experimental work on rabbits, in which he produces renal insufficiency by removing or destroying approximately 70% of kidney parenchyma.

Estimation of urea-nitrogen and creatinine and blood pressure readings were made. The kidneys were examined in those rabbits which died. The feeding of the rabbits was taken into consideration.

These experiments indicate that a marked reduction of kidney substance in rabbits does not result in hypertension, even where prolonged insufficiency results.

MAYO CLINIC, ROCHESTER

THE ETIOLOGY AND TREATMENT OF NON-TUBERCULOUS PULMONARY ABSCESS: W. Whittemore (Surg., Gyn. and Ob., April, 1924). Most cases of non-tuberculous pulmonary abscess follow the administration of general anesthesia in operations on the upper respiratory tract, in which material of some kind is aspirated into the lung. Pneumonia comes next in frequency and septic infarction next. There are many other less frequent causes.

The treatment in these cases consists of the following:

1. Expectant.
2. Artificial pneumothorax.
3. Bronchoscopy.
4. Operation.

Expectant treatment means general measures and gravity drainage by postural means two or three times a day. The number of cures effected by expectant treatment varies from 7 per cent to 51 per cent. This treatment can be safely continued so long as the patient improves, but surgery should be considered if improvement ceases or if the patient's general condition becomes worse.

Artificial pneumothorax may be employed in conjunction with postural drainage and should be continued over a period of from three months to a year. The presence of strong adhesions contraindicates and makes this treatment of little avail. Artificial pneumothorax is very valuable in determining whether or not adhesions are present and where. The dangers attending artificial pneumothorax are air embolism and rupture of an abscess with resultant empyema.

Aspiration through a bronchoscope in the hands of a specialist in early cases is sometimes successful, especially if a foreign body which was the primary cause of the condition is removed. Suggestion is made of this method of treatment in surgical cases which do not do well after operation.

In general, if there is a large amount of foul sputum, marked general sepsis and the abscesses are situated in the periphery of the lung with a demonstrable fluid level by x-ray, operation is indicated and is usually attended by favorable results. In cases in which no improvement occurs in 4 or 5 weeks, or if the general condition becomes worse, operation is indicated. The operative procedures in cases in which adhesions are present should all be done under local anesthesia and consist of opening into the abscess with the finger and instituting drainage with a very soft rubber tube. In cases in which there are no adhesions, the pleural cavity is explored to locate the abscess by palpation and the area is fixed to the chest wall with sutures, leaving a gauze pad over the abscess itself. This is done under some form of differential pressure anesthesia. The one preferred by the author is gas and oxygen through a

snug mask. In five days the wound can be reopened and the abscess opened as described.

Acute abscesses should be drained four or five weeks or longer and the chronic cases may have to be drained from three to six or more months.

From 60 to 70 per cent of the cases operated on can be permanently improved or cured. Five per cent die from hemorrhage after a few months.

W. P. HERBST.

SURGERY OF THE THORAX: D. B. Phemister (Surg., Gyn. and Ob., April, 1924). The factors that bring about expansion of a collapsed lung in acute empyema with drainage, where stabilization of the mediastinum has occurred are:

1. The pull of the contracting granulations on the visceral pleura at its reflection onto the parietal pleura as the two layers fuse, and the cavity is gradually obliterated.
2. The positive pressure within the collapsed lung produced by the entrance of air from the opposite side during forced expiration.
3. The negative pressure in the empyema cavity present during inspiration, when the diameter of the drainage opening is smaller than that of the main bronchus on the affected side.

The first factor is the most important. The creation of the most favorable conditions for wound healing should receive first consideration in treating this condition. Simple drainage is essential and the tube cannot be left in too long. Fibrin in the pleura is objectionable only in that it is partly replaced by granulations which thicken the pleura. Irrigation in acute empyema is only indicated when there are sloughs and where there is a large amount of fibrin.

X-RAY TREATMENT OF PERTUSSIS: R. R. Struthers (Canadian Medical Association Journal, February, 1924), (Arch. of Ped., May, 1924). Struthers reports a series of 45 cases treated in Montreal in three months. The first cases were treated by short exposures every other day for two or three treatments; most cases were treated by a large single exposure. Of the 48 cases, 7 showed prompt cure, the whooping and vomiting ceasing usually within 24 hours and not returning. Twenty cases or 45 per cent were relieved, showing amelioration of symptoms, within four or five days. Eighteen cases or 40 per cent were not improved appreciably. Conclusions are: 1. The larger the dose of the ray the greater the apparent improvement; all the prompt cures except one received the larger dose. 2. The earlier in the paroxysmal stage the treatment is given the greater is the probability of relief.

R. N. ANDREWS.

CAUSES AND TREATMENT OF OTITIS MEDIA, OBSERVATIONS ON TWO HUNDRED AND THIRTEEN CONSECUTIVE HOSPITAL ADMISSIONS: David T. Smith (*Amer. Jour. of Dis. of Child.*, July, 1924). In 613 admissions, 33.4 per cent of the children either had otitis media when they came in or developed it while in the hospital. The race and sex of the patient seemed to have no relation to the incidence of the disease. There was a definite seasonal variation. In February, 47.3 per cent of the patients had otitis media; in July only 23.6 per cent of the children were attacked. The most susceptible period was between the ages of 3 and 15 months. In this group more than 50 per cent of the children had otitis media. Patients with pneumonia, dysentery, nasal diphtheria, pertussis and pyelitis developed otitis media in 50 per cent or more of the cases. Those with the condition of prematurity, nephritis and the noninfectious diseases showed ear infections in less than 21 per cent. Hemolytic streptococci were isolated from the aural discharge in 56 per cent of the fifty cases cultured.

Practically all the gram-negative bacteria found in the ears of patients suffering from otitis media, except pyocyanus bacilli, are killed by an 0.5 per cent solution of sodium hydroxy-mercuri-benzophenone sulphonate. One of the difficulties with the ordinary method of treatment is the fact that only the external canal is treated; the organisms in the middle ear are not reached. After trying a number of solutions it was found that ordinary commercial hydrogen peroxid diluted one-half with water was the most efficient irrigating fluid. An ordinary medicine dropper with a good stout rubber bulb is the most useful and practical instrument to use. The peroxid liquefies the pus and at the same time serves as an indicator of the presence of more pus. So the mothers and nurses were instructed to irrigate the ears until the peroxid no longer frothed. After the irrigation, the excess of fluid in the external canal was removed by swabbing with a little cotton. After this the antiseptic penetrates into the middle ear and attacks directly the organisms responsible for the discharge. Not a single case of mastoiditis developed in a series of seventy-five acute and chronic cases which were irrigated with this solution.

Pyocyanus bacilli are readily eliminated by treatment with 2 per cent acetic acid, or preferably with 0.5 per cent of the sodium solution which contains 2 per cent acetic acid. It was found that acetic acid could be combined with the sodium solution. Enough glacial acetic acid was added to the 0.5 per cent sodium solution to make a 2 per cent solution of acetic acid. This solution was just as efficient in killing bacteria of the colon group as the sodium solution alone, and it killed pyocyanus in higher dilutions than acetic acid.

All the gram-positive bacteria found in otitis media are readily killed by gentian violet except streptococci. Neutral acriflavine has been proved more potent in the treatment of otitis media associated with streptococci, but even this drug is not entirely satisfactory. Twenty cases of chronic otitis media were cured by local chemotherapy in an average of seven days each. Sixty cases of acute otitis media were cured in an average of thirteen days each.

R. N. ANDREWS.

THE CLINICAL VALUE OF THE ROUTINE EXAMINATION OF BLOOD SMEARS IN THE DIAGNOSIS OF PERTUSSIS: A REPORT OF 300 CASES: Henry Heiman (*Arch. of Ped.*, June, 1924). Thus far but little has been accomplished in diminishing the incidence or severity of whooping cough. Pertussis vaccines have proven to be of little value either in the prevention or cure of the disease. The intracutaneous reactions for testing immunity have not been successful. One of the chief obstacles at present in preventing the spread of whooping cough is the difficulty of early diagnosis. From this viewpoint, the author presents the results of the examination of blood smears in 300 cases of pertussis and pertussis suspects from private practice, observed during the past five years.

Frohlich found a constant leucocytosis and lymphocytosis but concluded that the blood examinations were of no great value because the changes did not appear early enough in the disease. Churchill, from blood examinations of 35 patients, concluded that there was a lymphocytosis in 85 per cent of the cases. Ashby studied 100 cases of whooping cough and says: "Thus if a child who has been known to have been exposed to the infection of whooping cough starts with a cough, a blood examination will very likely show whether it is going to be whooping cough and then isolation can be undertaken early."

In the author's study of 300 cases of whooping cough and whooping cough suspects, his aim was to perform the simplest, most rapid blood examination in order to make it a more general routine procedure in private practice. He based his test only on a relative lymphocytosis. No total white blood counts were done to determine the leucocytosis present. A blood smear was taken in each case and stained with Jenner's dye. One hundred white cells were counted and for practical purposes a simple division, including only polynuclear cells and lymphocytes, was made. The eosinophilic leucocytes were included in the polynuclear and the transitional cells in the lymphocyte counts. Small and large lymphocytes were grouped together. The entire procedure takes but a very few minutes and can be performed in the course of routine office examinations on all suspicious cases. The common "cold," nasopharyngitis, bronchitis and laryngitis do not show this lymphocytosis.

The results of the examination of blood smears in 300 cases of pertussis have been presented, not to demonstrate any new and positive method for diagnosis, but to emphasize the almost constant occurrence of lymphocytosis as a very useful aid in the early detection of this serious infection of childhood. The procedure is simple and rapid and may be employed in the routine examination of all suspicious cases.

R. N. ANDREWS.

MENINGEAL HEMORRHAGES IN THE NEW-BORN AND THEIR REMOTE CONSEQUENCES: Alfred Gordon (*Am. Jour. of Dis. of Child.*, April, 1924). The cause of meningeal hemorrhages is, principally, the tearing of the membranes due to their overstretching, which leads to rupture of the blood vessels. To produce a tear, there must be cranial stress. Since the latter is frequently the result of protracted, difficult labor, with instrumental delivery, the obstetrician should bear in mind that the force used in the application of forceps should not be excessive,

or should not be applied to the wrong diameter of the head, as, for example, the anteroposterior diameter. Forceps are useful, and in many instances have been responsible for saving lives, but they may also be responsible for injuries in the fetus leading to consequences which have a direct bearing on the later physical and mental development of the child.

The preventive aspect lies in the consideration of all forces that are liable to lead to tearing of the meninges and the blood vessels. Wrong presentation and position of the fetus and other causes of difficult labor, such as prolapse of umbilical cord, the use of instruments or various manipulations in the delivery of the fetus, are all factors that cannot be overestimated in the production of cerebral hemorrhages and the tearing of the meninges.

Besides the preventive phase, consider briefly the therapeutic aspect of meningeal hemorrhage. With a certain degree of possible errors, supratentorial hemorrhages, generally speaking, present a somewhat different clinical picture from the infratentorial type. In the former, the blood spreads over the hemispheres of the cerebrum; in the latter, over the hemispheres of the cerebellum but also into the medulla. In the former, the blood cannot go beyond the lower surface of the tentorium; in the latter, the blood reaches the subarachnoid space and may extend into the spinal canal.

For these reasons, in the supratentorial hemorrhage at birth, one finds a bulging fontanel and a group of nervous phenomena, such as sleeplessness and great restlessness and convulsive seizures. In infratentorial hemorrhage, there is considerable depression, apathy, somnolence, early cyanosis, vasomotor and respiratory manifestations and rigidity of the neck muscles. In view of the anatomic differences, respiratory and other bulbar disturbances will not be observed in the cases of supratentorial hemorrhage.

Cyanosis is late in appearing and, when it does appear, is not pronounced in the supratentorial hemorrhages, but is early and very pronounced in the infratentorial cases; the anterior fontanel is at once bulging and early in appearance in the supratentorial, but slowly distending in the infratentorial cases. For anatomic reasons, in infratentorial cases lumbar puncture may be of considerable benefit. In the supratentorial cases lumbar puncture does not avail much, as the blood cannot reach the subarachnoid cavity easily.

Cushing, who obtained four complete recoveries in nine cases, is of the opinion that no hesitation should exist in operating on such young infants, in view of the fact that the new-born can withstand cranial operations better than any other operation and that much less traumatism is created by an operation than by the passage of the head through the pelvis during birth.

R. N. ANDREWS.

HEMORRHAGE OF THE NEW-BORN: Floyd Clarke (Arch. of Ped., May, 1924). Schloss and Commiskey have classified hemorrhage in the first few days of life as follows:

- (1) Traumatic—from obstetrical or surgical procedure.
- (2) Accidental—illustrated by insecure tying of the cord.
- (3) Spontaneous—without apparent cause.

Frequency:

Warwick, in a series of autopsies on new-born infants, found cerebral hemorrhage in 50 per cent of one series, and 42 per cent in another. She also found hemorrhagic disease of the new-born accompanying cerebral hemorrhage in 20 per cent of her series. In the Boston Lying-In Hospital, cerebral hemorrhage occurred once in every 300 deliveries.

Cause:

Trauma, due to a faulty application of forceps, or to some complication of a difficult labor, is well recognized. Another factor is intrauterine asphyxia, thereby raising the fetal blood pressure. There exists also a definite disease, viz., hemorrhagic disease of the new-born. In this peculiar disease, limited to the first few days of infancy, there occurs a deficiency of prothrombin, in the blood, and a prolonged coagulation and bleeding time.

Diagnosis:

These infants have a peculiar sharp cry, the fontanel is frequently bulging, they are spastic, disinclined to nurse, and occasionally have convulsions. In hemorrhagic disease of the new-born, the blood is usually apparent, the baby exsanguinated and in shock.

Prophylaxis:

The author believes that the mortality from hemorrhagic disease of the new-born would be less if every new-born babe were given a routine test as to his blood coagulation and bleeding time.

Treatment:

Repeated lumbar punctures may be done to help in decreasing the intracranial tension. Depending on the location of the hemorrhage and its extent, surgical procedure should be resorted to. In hemorrhagic disease of the new-born, the injection of whole blood is curative. Thirty c.c. of blood should be injected at one time and repeated as evidenced by coagulation and bleeding time tests, or by the appearance of blood. Rodda asserts that if the injection of blood from one donor is not curative, a second donor's blood should be used. It can be injected intramuscularly, intravenously or intraperitoneally with complete success.

About a year ago Dr. G. F. Still of London made the statement to a number of us that he considered gelatin given by mouth as valuable in the treatment of hemorrhagic disease of the new-born as the injection of blood. His opinion is of value.

ROENTGENOLOGY

SUPERVISORS:

LEO G. RIGLER,

MPLS. GEN'L HOSPITAL, MINNEAPOLIS

A. U. DESJARDINS,

MAYO CLINIC, ROCHESTER

THE ROENTGENOLOGIC DIAGNOSIS OF DIA-PHRAGMATIC HERNIA WITH A REPORT OF SEVENTEEN CASES: Carman and Fineman (Radiology, v. 3, p. 26, July, 1924). Seventeen cases are reported in considerable detail.

The following conclusions are derived from this study:

1. Ordinarily diaphragmatic hernia may be easily demonstrated on roentgenologic examination but failure occasionally occurs on the first examination. This may be explained on the basis of the following factors: (a) that it develops as a sequel to paradiaphragmatic purulent processes, trauma, or lacerations; (b) that spontaneous temporary reductions may occur; (c) that only one of a double hernia may be demonstrated; (d) the opaque medium may not pass through the opening due to strangulation or position; (e) solid viscera may be the only contents of the sac so the administration of opaque media will not reveal it.

2. Hernia of the kidney may be demonstrated by pyelography.

3. Diaphragmatic hernia must be distinguished from mechanical elevation and true eventration of the diaphragm, hour-glass stomach, and esophageal diverticula.

4. It is important to determine the length of the oesophagus to rule out the cases of congenital short oesophagus which are inoperable.

5. Chest symptoms often lead to roentgenologic studies but frequently the condition is mistaken for other chest diseases before the use of the opaque medium.

6. An attempt should be made to ascertain the exact site of the hernial opening in order to direct the surgical approach.

Numerous illustrations are given, particularly to demonstrate the roentgenologic appearance of the chest in diaphragmatic hernia, without the use of the opaque medium, and to compare it with other chest conditions.

The bibliography is of great value.

LEO G. RIGLER.

SOME CONSIDERATIONS IN THE TREATMENT OF CARCINOMA OF THE ESOPHAGUS: Quick (Am. Jour. Roent. and Radium Therapy, May, 1924). Carcinoma of the esophagus up to the present time is fatal in practically 100% of the cases. This may be partially due to failure to recognize the disease in its early stages, and partially to the resistant character of the tumor and its inaccessibility. Dysphagia is one of the earliest symptoms. Frequently growths are overlooked in the roentgen examination and early esophagoscopy is urged.

The treatment is only palliative. Torek's successful surgical removal is the only one on record. Lilienthal's direct exposure by surgery may aid in the treatment by permitting direct radiation to the tumor.

The author has observed 196 cases in the past seven years. The first of these were treated by direct application of small doses of radium through the esophagoscope, which are very effective in controlling ulceration and hemorrhage. The growth of the tumor is not affected. Intraesophageal application of larger doses causes swelling and obstruction. External uses of massive doses by means of the radium pack is impractical. The best method is high voltage roentgen ray, which in his experience adds years to the patient's life. Direct application of small doses of radium is used in combination.

Quick advocates very emphatically external gastrostomy at the very onset of symptoms. Gastrostomy late in the disease is usually fatal. He believes it should be done at once even if obstruction is minimal, as it is imperative to keep up the patient's nutrition. In their last cases the combination of early gastrostomy and high voltage roentgen therapy has resulted very favorably.

BOOK REVIEWS

BOOKS RECEIVED FOR REVIEW

MANUAL OF DISEASES OF THE EYE. Charles H. May, M.D., Director and Visiting Surgeon, Bellevue Hospital, N. Y., etc. Eleventh edition, revised. 374 illus. including 23 plates, with 73 colored figures. Cloth, \$4.00. New York: William Wood and Company, 1924.

GOITER: NONSURGICAL TYPES AND TREATMENT. Israel Bram, M.D., Instructor in Clinical Medicine, Jefferson Medical College, Philadelphia. New York: The MacMillan Company, 1924.

CIRCULATION IN HEALTH AND DISEASE. Carl J. Wiggers, M.D., Professor of Physiology in the School of Medicine, Western Reserve University, Cleveland, Ohio. 641 pp. Second edition, 1923. Cloth, \$7.50. Philadelphia and New York: Lea and Febiger.

This very comprehensive and scholarly book deals with the physiology and pathological physiology of the heart and circulation.

The first portion of this work deals with the normal physiology of circulation. The properties of the heart, cause of the heart beat, nervous enervation, sequence of events, and blood pressure are gone into in a most searching and thorough analysis. Physiology of the pulmonary and peripheral circulation complete the first section.

"Graphic Methods for the Clinician" are considered next. These include the sphygmograph, phlelogram, electrocardiogram and the interesting but not so well known photokymograph. The questions of venous and capillary pressure are also included here. Apparatus, technic and clinical interpretation are very explicitly handled.

The last section, "Diseases of Heart and Circulation," applies the foregoing in a thorough review of symptomatology and diagnosis. The classification of abnormal cardiac rhythms is simple, clear cut and seems to us to be the most understandable of the classifications of this disorder.

Many graphs make even more attractive this extremely worth-while book.

BURTON ROSENHOLTZ, M.D.

PHYSIOTHERAPY TECHNIC: A Manual of Applied Physics. C. M. Sampson, M.D., formerly of the Physiotherapy Service, Walter Reed U. S. Army General Hospital, Washington, D. C., etc. 443 pages. 85 illustrations. Cloth, \$6.50. St. Louis: C. V. Mosby Co., 1923.

In reviewing this book one is impressed by the author's sincere enthusiasm for this comparatively young field of therapeutic medicine. His experience has been extensive, his results as claimed in his book and lectures most astonishing. The book contains many helpful suggestions and is indeed instructive; however, one must not lose sight of the fact that there are still other therapeutic agents equally important.

The chapters dealing with high frequency and diathermy give one a good working foundation for this special therapeutic agent. A thorough description of the apparatus and its application is discussed in a manner that is easily understood. In our experience converse heat (diathermy) has a distinct place in therapeutic medicine. It is of great value in the after-treatment of fractures and sprains and wherever heat is indicated. It has a great advantage over other types of heat in that it will heat most distant parts. The author gives in detail a description of stimulative and sedative diathermy technic. Knowledge of the agent one is using is of primal importance to accomplish the best results.

Ultra violet light is a second great agent described in this book. It is very important and has a very definite place in medicine. More space in this chapter might well have been devoted to case illustrations, and the application of ultra violet ray in some of the more common diseases. The chapters on hydrotherapy and massage are important although somewhat abbreviated. The use of the various electrical modalities such as static, faradic and galvanic currents are described in some detail.

The book serves a definite purpose in that it brings before our profession the importance of physiotherapy and its agents. It emphasizes the fact that to accomplish results one must be familiar with the apparatus, its proper application and its limitation. It does give one a better knowledge of the material one is using.

NASAL DEFORMITIES*

GORDON B. NEW, M.D.

Section on Laryngology, Oral and Plastic Surgery,
Mayo Clinic

Rochester, Minnesota

I am reporting six cases to illustrate the method of treatment of certain types of nasal deformities, including saddle-back deformities, humps, angiomas, the use of full thickness skin grafts, and the reconstruction of part of the lower third of the nose.

Fig. 1 (Case A455091). Saddle-back nasal deformity.

CASE 1 (A455901). *Saddle-back deformity.*—The patient came to the Clinic February 9, 1924, for the correction of a nasal deformity following an accident ten years before. He had had no treatment or operation since then (Fig. 1). A lead pattern was made of the size of the cartilage that would be necessary to fill the deformity. Under block and local anesthesia, a piece of cartilage from the eighth rib was removed. Then an incision was made in the columella below the tip of the nose, and by means of small, curved, blunt-tipped scissors a pocket was made over the bridge of the nose, care being taken to stay close to the nasal bones. The piece of rib cartilage, after being shaped to the correct

size, and the perichondrium being removed, was inserted to elevate the deformity, and the incision closed with dermal sutures. Figure 2 shows the patient after operation.

Comment.—Saddle-back nasal deformities are best treated by the insertion of rib cartilage, which can readily be taken from the seventh or eighth rib, under local anesthesia. It may be inserted either through an incision across the bridge of the nose, or one just below the tip in the columella. The latter incision is less noticeable, and the results in this group of cases are very satisfactory.

CASE 2 (A454026). *Nasal hump.*—Ten years before examination at the Clinic, the patient had bumped the bridge of the nose, and the nose had always been a little larger at this point. Ten months before, a similar accident occurred and after this, an enlargement of this part of the nose was noticed. Examination January 29, 1924, revealed a bony thickening over the lower end of both nasal bones. The thickening was quite hard, but did not feel like a neoplasm (Fig. 3). January 31, 1924, under local anesthesia, the bony hump was rasped off. The incision was made inside the left nostril about 1.25 cm. above the vestibule.

Fig. 2 (Case A455091). Saddle-back nasal deformity corrected by inserting a piece of rib cartilage through an incision in the columella just below the tip of the nose.

Through this incision, by means of small, blunt-tipped, curved scissors, the skin and subcutaneous tissue was elevated over the bridge of the nose. The bony hump was then rasped off by means of specially made rasps of varying coarseness, which are carried up through the incision, and the bone removed. Following the removal of the hump, gauze pressure was applied by means of adhesive plaster on

*Read before the Southern Minnesota Medical Association, Mankato, Minnesota, May 19, 1924.

the bridge of the nose. At the same time a vaseline pack was inserted into the left nostril, thus preventing the formation of a hematoma. The intranasal gauze pack was removed after twenty-four hours, and the pressure removed from the outside of the nose after three or four days (Fig. 4).

Fig. 3 (Case A454026). Nasal hump.

Fig. 4 (Case A454026). Postoperative picture. The hump was rasped off through an incision inside the left nostril by specially shaped rasps.

Comment.—While there are various methods of removing bony nasal humps, the method of rasping them off through an incision inside the lateral wall of the nose is most satisfactory, as it eliminates entirely any external scarring. Infection has occurred in only one case; this was readily taken care of with hot dressings and did not interfere with the cosmetic result.

CASE 3 (A118722). *Angioma of the nose and cheek.*—The patient was brought for examination November 7, 1914, for an angioma of the left side of the nose and cheek. It had been noticed at the age of two weeks. The child had had multiple operations, silk-worm sutures being used outside the cheek in an attempt to scar down the angioma. At the time of examination, there was an extensive angioma of the left cheek, bulging the left side of the nose and extending into the inner canthus. It was impossible to make out the complete outline of the nose. There was marked scarring over the tumor, the result of the repeated operations (Fig. 5). Radium treatment was advised, most of which was given by inserting radium directly into the tumor. A small incision was made into the normal tissue, either inside the mouth or outside the cheek, at some distance from the tumor, and then by means of a curved, small forceps, a channel was made into the center of the tumor, and a radium tube attached to a silk thread inserted directly into the tumor. These treatments were repeated no more often than every three months, the usual dosage being in a 25 mg. tube, left in place for from five to ten hours. September 16, 1919, a pedicle flap was brought down from the left temporal region to correct partially the ectropion of the lower lid, the angioma having been entirely destroyed by the radium (Fig. 6).

Fig. 5 (Case A118722). Cavernous angioma of the nose and cheek. Note the scarring over the surface from previous operations.

CASE 4 (A218918). *Angioma of the nose.*—The child came to the Clinic January 11, 1918, because of an angioma of the tip of the nose, 2.5 cm. in diameter; she was perfectly well otherwise. The angioma affected the entire tip of the nose, causing marked deformity (Fig. 7). January 15, 1918, a 25 mg. tube of radium was inserted directly into the angioma through a small incision at the juncture of the nose and left cheek. The radium was left in place for twelve hours. No other treatment was given. Figure 8 shows the patient six years later, nothing further having been done for the condition.

Comment.—Radium is specific for cavernous angiomas. In 1917 I reported a group of cases illustrating this fact. Previous to this time, Abbe and others had used it in this type of condition with good results. In infants and young children the results are much more satisfactory than in

adults. The most satisfactory method of treatment is inserting a small radium tube directly into the center of the tumor through a small incision in the skin or mucous membrane, some distance from the tumor. This allows a valve-like action of the skin between the incision and the tumor, which prevents bleeding. The results in all of this group of cases have been very satisfactory.

CASE 5 (A454995). *Full thickness graft replacing basal-cell epithelioma of nose.*—The patient came for examination February 11, 1924, with a lesion over the bridge of the nose, of five years' duration. Various types of treatment had failed to afford relief. There was a thickened lesion over the bridge of the nose about 5 by 3.75 cm. The skin was movable. The condition was a basal-cell epithelioma of rather a low grade type (Fig. 9). February 14, 1924, the lesion was widely excised and the skin replaced with skin from the back of the right side of the neck. Gauze pressure was applied for ten days and the entire area of the

Fig. 6 (Case A118722). The same patient five and one-half years later. Tumor was removed by means of repeated radium treatment. The scarring of the cheek is the result of previous operations.

graft adhered, except for one small area over the bridge of the nose, apparently the result of too much pressure. This, however, epithelized quickly (Fig. 10).

Comment.—This case illustrates the value of full thickness grafts in replacing low grade, basal-cell epitheliomas. It should not be used in cases of active basal-cell epitheliomas if there is any likelihood of recurrence. It is much more satisfactory than the use of a pedicle flap, and saves the patient at least six weeks' time in the hospital. The graft being taken from the back of the neck is practically the same color as the rest of the skin about the nose, so that the cosmetic result is exceptionally good. Keller, Parce, Blair and others, have called attention to the value of such grafts.

Full thickness grafts are used on the face and neck wherever there is sufficient supporting tissue to allow of firm pressure after operation, as in

Fig. 7 (Case A218918). Cavernous angioma of the tip of the nose.

corrections of ectropion of the lips, the excision of scars about the face, following the removal of an inactive basal-cell epithelioma where a plastic closure is impossible, in correcting the scarring of the chin and neck, and in grafting the distal end of pedicle flaps where a double epithelized flap is required. The graft is cut from the neck or leg, the same size as the area to be grafted. This is done by using a pattern. The grafts are used without fat, and sutured in place with dermal sutures. Gauze is applied evenly over the graft and firm pressure applied with adhesive plaster. The part is kept absolutely immobile for at least ten days, and the dressing is not removed before that time. It is best to use the grafts on fresh, clean wounds. The grafts may be made up to 7.5 cm. in diameter; I do not believe it advisable, as a rule, to use the

Fig. 8 (Case A218918). The same patient five years later, following one radium treatment.

grafts much larger than this on account of the difficulty of keeping them under even pressure. It is best to make repeated grafts rather than to at-

Figs. 11 and 12 (Case A445324). Loss of part of the lower third of the nose following lupus, and the use of a plaster.

Fig. 10 (Case A454995). The postoperative result after excising the basal-cell epithelioma and replacing it with a full thickness graft from the neck.

Figs. 13 and 14 (Case A445324). Nose built up by means of a pedicle flap from the forehead with a full thickness graft on the distal end. Note the fact that the vestibules of the nostril are open, owing to the use of the full thickness graft.

tempt to use too large ones. It is not advisable to try them on the neck in very young children on account of the difficulty of keeping the part absolutely quiet for the required period. If it is attempted, it is best to keep the child in a Bradford frame, with lead shot bags on either side of the head to prevent movement. I believe that the essential points are: to cut the graft free from fat, to have the area to be grafted dry, to apply firm, even pressure over the graft, and to keep the part absolutely immobile, not disturbing the dressing for at least ten days.

CASE 6 (A445324). *Loss of part of lower third of nose.*—

The patient came to the Clinic October 23, 1923, for reconstruction of the nose, which had been destroyed by a plaster and by lupus. The lupus had started three years before, and she had had various types of treatment, including x-ray. She obtained a plaster from a peddler and applied it herself; this caused most of the deformity (Figs. 11 and 12). The patient was well otherwise. October 29, 1923, a pedicle flap with the pedicle just to the right of the median line of the forehead, and the flap extending up to the left forehead, was outlined and elevated, under local anesthesia, and a full thickness graft inserted underneath the distal end. About two weeks later, the full thickness graft having taken perfectly, the flap was elevated. Three days later, it was brought down in place over the nose, and after the margins had been freshened, and sutured in place

over what was left of the columella, was attached laterally to what remained of the ala. December 10, 1923, after a preliminary cutting off of the pedicle in stages, this cutting off was completed, the distal end of the flap sutured back in place on the forehead, and the flap over the nose sutured in place. The patient was then allowed to go home for three months as the nose appeared quite large. She returned March 8, 1924, and the superfluous part of the flap was trimmed down in three stages, to improve the appearance. Figures 13 and 14 show the patient April 4, 1924, shortly after removal of the sutures. Note the fact that the use of the full thickness graft underneath the distal end of the flap has maintained a good right nostril (Figs. 13 and 14).

Comment.—By far the most satisfactory place to secure a pedicle flap for reconstruction of part of the nose is from the forehead. Taking the flap from the cheek causes unnecessary scarring, and the color of the flap from the neck is not as satisfactory as that obtained from the forehead. In order to obtain an open nostril in these cases, the use of full thickness grafts underneath the distal end of the flap is very essential. The full thickness grafts are more satisfactory than the Thiersch grafts for this purpose. It is best to delay the final shaping up of the nose for at least three to six months after the flap has been sutured onto the nose, on account of the shrinkage that takes place.

An Anesthetic Monopoly.—U. S. patent 1,491,740 was issued April 22, 1924, and was assigned by the patentee to the S. S. White Dental Manufacturing Co. The specifications of the patent describe a process for making a nearly anhydrous nitrous oxid. The patentee claims patent rights, not only on his process for reducing the moisture-content and in nitrous oxid manufactured by that process, but on all nitrous oxid whatsoever conforming to the arbitrary standards stated in his claims, no matter how manufactured. The process, if novel, is presumably worthy of patent protection. But nitrous oxid has been recognized as a chemical entity since 1776, and it has long been possible to reduce by various processes the moisture-content incident to its manufacture. By what process of reasoning the patentee claims to have "invented" nitrous oxid of low moisture-content and how the patent office came to concede his claim, are beyond the comprehension of persons not versed in the mysteries of patent logic and patent law. It would not be to the public interest for any concern to obtain a monopoly on nitrous oxid free from moisture. It is to be hoped that the S. S. White Dental Manufacturing Company will not be able to secure a monopoly on dry nitrous oxid (Jour. A. M. A., July 26, 1924, p. 287).

THE CONDUCTION MECHANISM OF THE HEART*

OLGA S. HANSEN, B.S., M.D.

Minneapolis

The change observed in titles of papers on conditions of the heart and circulation in the last few years is most striking. Instead of being concerned with the purely structural changes of the muscle and valves of the heart and writing about valve lesions and their results in the pumping power of the heart, physiologists, anatomists and clinicians are thinking and investigating in terms of the origin and spread of the impulse that makes the heart act as a pump. The strides that have been made in overtaking the truths of the physiology and pathology of the heart-beat are enormous when it is noted that the condition of auricular fibrillation with which all clinicians are now familiar was first analyzed and explained by Lewis in 1909, and that the electro-cardiograph was first used by Einthoven in 1903.

In order to understand the conduction mechanism of the heart as it has been proved to exist, and to realize the relation of the different parts to each other, it is well to trace its development from its fetal beginning.

Early in embryonic life the large veins, called the Ducts of Cuvier, or common cardinal veins, bringing the blood from the head and the body, unite, and in uniting form the sinus reuniens, which in turn empties into the primitive one-chambered auricle. This sinus corresponds closely to the sinus venosus of the frog, which is a chamber into which the large veins empty and is separated from the auricle by the venous valves. Later, as the auricle is divided into two chambers and the heart grows in size, the sinus reuniens does not grow but is incorporated into the body of the right auricle at the point of junction with the superior vena cava. It is thought that the remains of this primitive tissue form the pacemaker of the mammalian heart. In harmony with this view is the fact that in the frog a ring of specialized tissue is found about the bases of the venous valves (between the sinus venosus and the auricle), and incomplete portions of such a ring are found in the higher animals at the points

*Read by invitation before the Consulting Medical Staffs of the Lymanhurst School for Tuberculous Children and the Parkview Sanitarium, November 27, 1923.

corresponding to the remains of these valves. In the frog the contraction of the heart originates in the sinus venosus, giving more force to this theory of origin of the pace-maker of the mammalian heart.

In the human and other mammalian hearts a small collection of peculiar muscular tissue, arranged in a complicated network bound together by connective tissue, is found at the junction of the superior vena cava with the right auricle and corresponds in location to the right branch of the embryonic veins. It is known as the sino-auricular node, or node of Keith and Flack, after the workers who described it. A second similar collection is found in the wall of the auricle at the base of the septum, in the neighborhood of the coronary sinus, and represents the left branch of the embryonic veins. This is known as the auriculo-ventricular node, or node of Tawara, and is the beginning of the connection between the auricle and ventricle.

From this auriculo-ventricular node a heavy band of specialized tissue known as the bundle of His, or the auriculo-ventricular bundle, passes down the ventricular septum and forks to the right and to the left ventricles. The fibres branch out into a complicated arborization which lines the ventricular cavities, and end in a network of Purkinje fibres, consisting of cells without striation and with large pale nuclei, lying just below the endocardium.

The bundles and fibres are covered with connective tissue sheaths, and the nodes in the auricle are richly supplied with blood-vessels and nerves.

In brief the conduction mechanism of the heart consists of remains of embryonic tissue collected in dense nodes held together by connective tissue, in the auricles, and of strands of specialized muscle fibres arranged in a parallel manner passing from auricle to ventricle and then branching out as a network into the ventricular muscle. It is thought that the primitive muscular tissue acted without nerves in the beginning but, as the nerves were supplied during fetal growth, they took over more and more control of the mechanism. The function of these collections of specialized tissue is to originate and transmit impulses, although it must be noted that any part of the heart muscle can perform these functions, with some degree of success.

The sino-auricular node, corresponding to the

remains of the right embryonic vein, is known as the pace-maker of the heart. Each normal heart-beat originates here and travels through the auricular muscle as an excitation wave, causing contraction of this chamber. The rate at which these impulses are sent down depends on the influence of the vagus and accelerator nerves in modifying the intrinsic rate of the node. The impulse spreads through the auricular muscle at the rate of 1,000 millimeters per second, in a circular motion, which has been likened to the widening circles made when a stone strikes water.

It is then carried by the auriculo-ventricular node and bundle to the ventricles and from here the impulse spreads from within outward, by means of the Purkinje fibres, which carry the impulse at a rate of 5,000 millimeters per second, five times as fast as the rate of spread through the auricle and ten times as fast as the rate of conduction through the ventricular muscle if stimulation is applied to the pericardial surface, instead of to the endocardial surface where the Purkinje fibres are located. These fibres carry the impulse so rapidly that the contraction of the ventricle is practically simultaneous, whether in the thickest or the thinnest parts of the ventricle. It is of interest to note that the conduction rate is most rapid through the parts of the conduction system richly supplied with glycogen, that is the Purkinje fibres, and that the breadth of these fibres is greater than that of any others. The glycogen content is less in the auricle, the ventricle, and the auriculo-ventricular node, in the order named, and the breadth of fibre is correspondingly less. At the same time the rate of conduction is slower in the auricular muscle than in the Purkinje network; in the ventricular muscle than in the auricle; and there is evidence that the auriculo-ventricular node has the lowest conduction time of all.

The nerves affect the action of the heart through the nodes in the auricle. The right vagus influences the sino-auricular node. The sino-auricular node is the pace-maker and so stimulation of the right vagus slows the heart. The left vagus influences the auriculo-ventricular node. This node is the beginning of the junction between the auricle and the ventricle, and so stimulation of the left vagus causes blocking of conduction between the chambers. Actually fibres from the vagi are so mingled that the action is not quite so clear-cut as the embryonic origin might indicate. Experiment-

ally stimulation of the left vagus affects both nodes about equally although the right nerve seems to be more specific in its action. The accelerator nerves have the same distribution of effect. Many physiologists have found that stimulation of the right accelerator nerve causes an increase of rate, while when the left nerve is stimulated contractions occur simultaneously in the auricle and ventricle, because of the overaction of the auriculo-ventricular node. Again this can be traced back to the distribution of the right nerve to the embryonic region, corresponding to the right vein in the embryo, and of the left to the auriculo-ventricular node corresponding to the embryonic left duct of Cuvier. Experimental heart-block is then produced by a change in the conducting power of the main neuro-muscular tract uniting the auricle and ventricle, by injury, by disturbed innervation, or by poisons.

In summary, the cardiac contraction originates with an impulse from the pace-maker, the sino-auricular node, passing as an excitation wave through the bands of auricular muscle. Then it is carried through the junctional tissues, the auriculo-ventricular node, the bundle of His and its branches to its arborization in the interior of the ventricle. The Purkinje fibres beneath the endocardium transmit the impulse to the ventricular

muscle, and so rapid is their rate of conduction that the spread through the ventricles is almost simultaneous, resulting in a contraction of the ventricle as a whole.

Once the contraction wave has passed and systole has occurred the heart muscle settles down to a diastolic period of refractoriness, and is then ready to respond to the next impulse which arises when sufficient contractile energy has been stored up. The vagus acts as the inhibitor and keeps the rate slow enough to bring about effective contractions. The balance between the vagus and the accelerator nerves maintains the rate best suited for the organism under all circumstances of rest and of exertion.

THE RISING TIDE OF BUREAUCRACY

A direct and immediate consequence of the over-multiplication of regulatory and inquisitorial laws is a corresponding increase in the number of offices and office-holders.

It is a profound mystery why the people of the present generation should so violently run after the very things which their forefathers so violently ran away from in 1776.

One of the chief indictments of King George set forth in the Declaration of Independence reads:

"He has erected a multitude of new offices and sent hither swarms of officers to harass our people and eat out their substance."

Can we believe that the signers of that historic Declaration would have been so ready to pledge their "lives," their "fortunes" and their "sacred honor" to its defense if they could have foreseen that a later generation would voluntarily consent to the creation of bureaus and commissions and to the appointment of officers a hundred-fold greater in number than King George and the British Parliament ever thought of imposing upon the Thirteen Colonies?

A recent authority has estimated that within the period in which the population of the United States increased ten per cent the number of persons holding civil office increased forty per cent, that the amount paid in salaries increased one hundred and fifty per cent, and that of males

old enough to hold a job one in every forty-seven is now in some kind of government employment.

The same authority estimates that of the total revenue collected by the U. S. Government, one dollar in every five is paid out in salaries, and that the total salary list of the Federal Government is now approximately equal to \$10.00 for each and every man, woman and child of the entire population, without including the sums paid to the immense army of state and municipal employees. At the present rate of increase, two more decades will see one adult in every ten holding some kind of public office, and paid from taxes collected from the other nine.

The growth of bureaucracy, like the growth of every other governmental evil, has been insidious. Always it has been concealed under the cloak of *pro bono publico*. Always the movement is alleged to be in the interest of public health, public safety, public morals, or is designated by some other fine sounding title. Most of those who advocate and those who assent to the creation of new offices are animated by the best of motives. The road to bureaucracy, like the road to perdition, is abundantly paved with good intentions.—*From an address delivered at the 24th annual Convention of the National Association of Retail Druggists, Detroit, Sept. 26, 1922. Reprinted from the Midland Druggist and Pharmaceutical Review.*

THE CLASSIFICATION OF THE IRREGULARITIES OF THE HEART*

HARRY OERTING, M.D.

St. Paul

Irregularities of the heart are so frequent, and their presence is so readily detected, that it is necessary to differentiate the various forms and to know their significance. An irregularity may be of no importance or it may mean a grave heart condition, and unless the underlying cause is recognized the patient may either have a serious heart lesion overlooked or he may be unnecessarily worried and subjected to a regime that will prevent him from living an otherwise useful normal life.

In order to readily arrive at a diagnosis it is essential to have some method of classification. Several classifications have been suggested by various authors but it is not within the scope of this paper to consider all of them and I have arbitrarily chosen the classification as suggested by Lewis in 1911 as the most practical for the present purpose.

The various irregularities of the heart will be taken up under the following headings:

1. Sinus Arrhythmia.
2. Premature Contractions. (Beats of ectopic origin or extra-systoles.)
3. Paroxysmal Tachycardia.
4. Auricular Flutter.
5. Auricular Fibrillation.
6. Heart Block.
7. Alternation of the Pulse.

1. *Sinus Arrhythmia*. — Sinus arrhythmia is that almost universal and relatively unimportant acceleration and slowing of the heart rate that accompanies normal respiration, being most marked in young individuals. Sinus irregularities are produced by interference with the rhythmic impulses at their origin and discharge. Normally the stimulus to contraction arises in the sino-auricular node, which lies in the upper anterior end of the sulcus terminalis. The sulcus terminalis runs from the junction of the right auricle and superior vena cava toward the inferior vena cava. This node consists of a specialized network of muscle cells and is richly supplied with the nerves of the heart. The contraction which starts in this node spreads

through the walls of both auricles to the auriculo-ventricular node and is then transmitted by the auriculo-ventricular bundle of His to the ventricles. The normal heart rate averages about seventy-two beats per minute and is under control of the vagi or inhibitory nerves of the heart. Many times the vagi act with excessive inhibition either persistently or spasmodically and the result is a uniform slowing or an intermittent slowing.

2. *Premature Contractions*. — Premature contractions, or extra-systoles as they are better known, and which terms will be used interchangeably in this symposium, are the results of impulses arising from a new site which may be located in the auricles, ventricles, or conduction system. Normally the impulse begins at the sino-auricular node, travels down the auricles to the A-V node and then through the bundle of His and its branches and is distributed simultaneously to the musculature of both ventricles. In premature contractions, or extra-systoles, the impulses are named according to their point of origin, as auricular extra-systoles, ventricular extra-systoles, etc. Extra-systoles occur before the regular time and disturb the normal rhythm of the heart, except in the interpolated forms. The contraction starts abruptly and travels quickly and in general does not tend to repeat itself. *Etiology*: This condition occurs in any cardiac disease where the walls of the heart are dilated or the heart is working against a high pressure; also in toxemic conditions due to digitalis, gastro-intestinal infections and the bacteria of the acute infectious diseases.

3. *Paroxysmal Tachycardia*. — Paroxysmal tachycardia is a condition of sudden acceleration of the heart rate. The abnormal focus is usually situated in the auricle and the normal sequence of contractions is maintained. A paroxysm may last a few beats and recur from time to time or it may last for hours or days. The attack begins and ceases abruptly. *Etiology*: Attacks occur at all ages and excitement or emotional disturbances are the chief excitants of an attack in those predisposed.

4. *Auricular Flutter*. — In auricular flutter the normal beats of the auricles are submerged by contractions of this chamber in response to a series of new impulses varying in rate from 200 to 350 per minute. "Our knowledge of clinical auricular flutter is too incomplete to permit of more than

*Presented before St. Paul Clinic Week, St. Paul, January, 1924.

speculation as to its exact nature. Reasons for believing that heterogenetic impulses stand to it in the relation of a causal factor have been adduced. It has to be borne steadily in mind that the condition is closely connected with fibrillation. It possesses a curious quality, namely, a tendency to persist in circumstances where the exciting cause appears to be no longer at work. In this it resembles fibrillation" (Lewis). Flutter is comparatively rare, is seen for the most part in the sixth and seventh decades of life and is always associated with heart block. *Etiology*: There is no apparent relation to the infectious diseases, but at times there is association with arteriosclerosis.

CONDUCTION SYSTEM OF HEART.
(Diagrammatic)

THE SINO-AURICULAR NODE(PACEMAKER) LOCATED IN THE RIGHT AURICLE AT THE JUNCTURE OF THE VENA CAVA, INITIATES EACH NORMAL IMPULSE TO CONTRACTION. FROM HERE THE IMPULSE SPREADS OVER BOTH AURICLES ARRIVING, BY THE SHORTEST ROUTE, AT THE AURICULO-VENTRICULAR NODE(BETWEEN AURICLES AND VENTRICLES). THIS IN TURN BECOMES ACTIVATED AND SENDS AN IMPULSE ON TO THE VENTRICLES THRU THE BUNDLE OF HIS. A BRANCH OF THIS BUNDLE GOES TO EACH VENTRICLE, AND SUB-DIVISIONS PROVIDE FOR THE SPREAD OF THE IMPULSE SIMULTANEOUSLY TO ALL PARTS OF BOTH VENTRICLES

5. *Auricular Fibrillation*.—Auricular fibrillation is a condition of total irregularity in rate, force and rythm of the heart, formerly referred to as delirium cordis or pulsus irregularis perpetuus, caused by stimuli from multiple foci in the auricles. There is no auricular systole, the

auricles being in diastole and fibrillating. The ventricles react only to a portion of the stimuli starting down the conduction system. *Etiology*: There are two general classes of cases where this condition is noted, i e., in mitral stenosis and when myocardial damage has occurred. Syphilis is not an etiological factor per se.

6. *Heart Block*.—In this condition there is a delay in or absence of response by the ventricle to impulses from the auricle. In the normal heart the auricular systole sends an impulse along the bundle of His to the ventricle. The bundle of His starts in the right auricle near the coronary sinus and proceeds forward and downward to the membranous septum of the ventricles, where it divides into two main branches, one on either side of the septum. The main branches then subdivide and are connected to the musculature of the ventricles through the complicated network of cells named after Purkinji. Whenever there is a disturbance of function in the bundle of His there is a disturbance in the normal beats of the heart. There may be a simple delay in the conduction time through the bundle of His. If the delay is prolonged sufficiently the ventricles fail to respond to some of the auricular impulses and we have the so-called dropped beats. The dropped beats produce a pause that breaks the normal rythm of the ventricle. As the degree of heart block increases the ventricular silences become more frequent and relatively simple ratios are established between the auricular and ventricular rates. With half the auricular impulses coming through we have a 2:1 heart block. This ratio may reach 4:1. In complete block no impulses from the auricles reach the ventricles, and each take up their own rate, which is 72 for the auricles and 33 for the ventricles. *Etiology*: This condition occurs at any age, predominating in males. It follows severe damage from rheumatic fever, chorea, and senile affections. The condition is not infrequent during the course of acute infectious disease. Syphilis is also one of the outstanding causes of heart block. The great bulk of the cases can be placed either in the rheumatic or the syphilitic group and in either case they are an expression of a deep seated and widespread affection of the heart muscle. In elderly people the condition often cannot be attributed to the above causes and is due to senile changes in the heart muscle itself. Block is also sometimes associated with metastatic car-

cinoma of the bundle of His. Digitalis is one of the prominent causes of heart block. Pathologically the main bundle of His or its branches or its auricular attachment are the seat of the lesion.

7. *Alternation of the Pulse.*—Alternation of the pulse is a condition in which the left ventricle while beating regularly expels larger and smaller quantities of blood. There is alternation of the pulse beats so that every other one is smaller or larger than the one just preceding. This condition is of obscure origin and the disturbance is dependent upon some unexplained anomaly of the ventricular systoles. The contractions of the ventricle are regular and each is preceded by a regular auricular contraction. *Etiology:* This condition is seen in two classes of patients: where the heart rate is unduly accelerated as in paroxysmal tachycardia, and in normal rates in elderly subjects. Males show a distinct preponderance. Pathologically there are no typical lesions. The condition has been noted in angina, hypertension, renal disease and fibrotic myocarditis.

"We must return to the basic idea that the granting of the degree of Doctor of Medicine means that a student is capable of handling the ordinary problems of general practice. This is certainly necessary before he can be safely trusted to advance in any special field. In the ordinary small community we find the general merchandise store. One can obtain here the essentials of human life in ordinary existence. If one wants any special appliance or something unusual it takes time to obtain delivery and one must either send or go to a larger field. This illustrates general practice and also the requirements for every medical man. In our larger centers we have the department store, where there is a marked extension of everything represented in a general merchandise store with experts in charge of each department. Medicine likewise is handled in this way where specialists in various lines are available. In the general merchandise store the proprietor knows everything that he has on hand and how to guide his customer to get promptly the essential things that he needs. In the general department store much is left to the customer himself. Without guidance he may over-purchase in a single department when his real needs lie in another. It is inevitable that there shall be these two forms of organization. One of the ways to protect the person who deals largely with specialists is to have the specialist understand thoroughly the essentials of general medical practice."—Extract from address by Dr. Ray Lyman Wilbur, President-elect of the A. M. A., at annual meeting of the California State Medical Society, May 16, 1922.

THE INSTRUMENTAL RECOGNITION OF CARDIAC IRREGULARITIES*

HAROLD E. RICHARDSON, M.D.

St. Paul

It has only been through the instruments of precision, the electro-cardiograph and the polygraph, that we have been able to determine the true nature and variety of the cardiac irregularities. We are all familiar with the terms "delirium cordis" and "extra-systole," which are remnants of our early clinical knowledge and which as the result of the use of these instruments are now more accurately recognized as "auricular fibrillation" and "premature contraction" respectively.

Because of its extreme delicacy and accuracy of definition, the electro-cardiograph stands in a class by itself in the study of the heart, particularly of the irregularities of this most vital organ. In this regard also, its co-partner, the polygraph, occupies a secondary, but very important, position, and is used by us to supplement the information obtained by the electro-cardiograph. The polygraph, being a portable and relatively simple instrument, readily lends itself to wide-spread clinical use.

THE ELECTROCARDIOGRAPH

Modern electrocardiography was made possible by (1) the discovery of Kölliker and Müller in 1885 of the fact that an electric current was generated by each beat of the frog's heart; (2) the observation of Ludwig and Waller in 1887 that similar currents generated by the human heart could be recorded by means of a capillary electrometer; and (3) the construction by Einthoven in 1903 of an extremely sensitive modification of Ader's instrument which made possible such experimental work as placed the electrocardiograph in the clinical field and justified the manufacture of commercial instruments.

Gradually a few instruments came into use in this country, and in 1912 Dr. Charles Lyman Greene, then head of the Department of Medicine at the University of Minnesota, secured the installation there of the first electrocardiograph in the North-

*This paper combines the essential points of two papers. The first, on "Practical Electrocardiography," was presented before the Ramsey County Medical Society, November, 1923; the second, on "The Instrumental Recognition of Cardiac Irregularities," was presented at the Ramsey County Medical Society Clinic Week Symposium on "Cardiac Irregularities," January, 1924.

LEAD III LEFT ARM TO LEFT LEG.

Normal Electrocardiograph

No arrhythmia. The "P" and "T" waves are all of good height and upright in all leads. The conduction time is 0.16 seconds (normal limits 0.12 to 0.18 sec.). No ventricular preponderance.

west. At present there are five in the Twin Cities available to all members of our profession.

The high initial cost (about four thousand dollars) together with the heavy expense of upkeep and operation, limits the number of purchasers of this instrument to the individuals or groups who have a sufficient demand for it. Fortunately neither possession of the instrument nor familiarity with its operation is necessary inasmuch as it is the completed, permanent, photographic record *alone* that is of importance to the physician, the actual process of registration revealing nothing.

Interpretation of an electrocardiographic record is a relatively simple matter. I shall demonstrate to you later that no atmosphere of mystery need envelop the instrument or its records. Their mysterious qualities disappear under the application of quite simple interpretative formulæ. One cannot doubt the great interest that has been aroused in the profession as a whole by the tremendous advances in the effective and timely diagnosis and treatment of heart disease by this indispensable instrument of precision, and it is only to be regretted that this interest has been curbed by the lack of a knowledge so easily obtainable.

I purposely omit a detailed description of the complicated, delicate instrument itself, as that would involve a departure from the direct purpose of this paper. With respect to the actual production of an electrocardiogram, one may say that it is a moving picture of the deflections of a microscopic filament, suspended between the poles of a

powerful electro-magnet, said deflections being caused by the conduction of the electric currents accompanying and reflecting the phases of the heart cycle. To each end of the conducting filament, an electrode is connected, and between these two electrodes the patient is placed, completing the circuit. The "so-called" action currents can be *led* across different portions of the heart and off from the body, according to the placing of the electrodes, hence the term "lead," of which there are three in regular use, indicated always by the Roman numerals I, II, III. Lead I gives the electrical activity of the heart as viewed from the top, i.e., across the auricles, and to obtain it the electrodes are placed on the forearms. Lead II gives the electrical activity of the heart through its main diagonal and necessitates placing the electrodes on the right arm and left leg. Lead III gives the electrical activity of the left side of the heart, the electrodes being placed on the left arm and left leg. You will see the necessity and importance of these three leads in following with me the lantern slides which are now to be shown.

No one should be permitted to get the idea that an electrocardiogram represents a complete, ready-made diagnosis of a heart condition. The electrocardiograph, like the x-ray, is a vital necessity in all careful and accurate studies of the heart. While it, like the x-ray, is absolutely indispensable to a complete cardiac examination, it in no way displaces or lessens the value or necessity of the classical clinical methods, but is, rather, an adjunct to

Right Ventricular Extrasystoles

In this case they follow each normal heart cycle. Evidence of the normally occurring auricular contraction is wholly buried in the diphasic extrasystolic wave as is usually the case. The "regularity" of the "irregularity" as reflected in the pulse is very confusing.

them. The information it supplies is exact and precise, and while it may at times simply confirm and amplify the clinical conclusions, it goes much further, giving vital facts such as are impossible to obtain by any other means. It shows not only the

Misleading Type of Auricular Fibrillation (lacking delirium cordis)

The "P" wave is absent. Multiple coarse undulations (fibrillatory waves) fill the diastolic period. Note that the ventricular rate is only 66 and that the "R" waves occur almost rhythmically. Lacking an electrocardiogram, this type of fibrillation is often unrecognized clinically, or is interpreted as a mere Sinus Arrhythmia. Pulse likely to be termed "regular," but a curious hesitant quality is apparent to one familiar with this not uncommon type. Strikingly good compensation may be attained without abolition of the auricular fibrillation in such cases.

exact heart rate and rhythm, but *exactly defines* any arrhythmia present, reveals the existence of ventricular preponderance, asynchronism of the ventricles, auricular hypertrophy, auricular pathology, auricular fibrillation no matter how masked or obscure clinically, ventricular fibrillation, auricular flutter, paroxysmal tachycardia with its point of origin, and sometimes the presence of the "drop" type of heart and alternation. It also shows the presence of hypotonus of the heart muscle, suggests the presence of chronic myocarditis and hyperthyroidism, and offers certain aids in evaluating heart muscle strength. It gives its most valuable information in its revelation of the presence of: (1) delayed conduction; (2) heart block of the ordinary type whether partial or complete; (3) sino-auricular and branch-bundle block; (4) defects in the arborization fibers; and (5) over-digitalization. It helps greatly in prognosis. It often unmasks silent, insidious heart lesions of middle age, otherwise undetectable, by unveiling branch-bundle block, arborization defects, and certain specific "T" wave inversions indicative of a grave heart condition. Our routine use of the polygraph has long since demonstrated its great value, but both in scope

and exactitude it is distinctly inferior to the electrocardiograph.

The electrocardiograph gives no direct information concerning the heart size, the valvular lesions, murmurs, the nature of heart tones, blood pressure, or decompensation. These are to be determined and evaluated by the other clinical methods. On the other hand, those conditions within the heart which are most obscure and least readily revealed by the usual diagnostic methods constitute the field par excellence of the electrocardiograph. Not only does this instrument give us a means of rounding out a diagnosis, but again and again it reveals the presence of a dangerous and wholly unsuspected heart lesion, unrecognizable by other methods of cardiac investigation.

In closing I would summarize as follows:

1. Interpretation of an electrocardiogram and a polygram is a relatively simple matter.
2. Both electrocardiogram and polygram are permanent records, giving within their scope most valuable and exact information concerning the heart's action.
3. Neither instrument furnishes a complete, ready-made diagnosis of a heart condition.
4. They do give vital information concerning the heart, of a sort that cannot be obtained by any other means.

It is obvious that both of these instruments make possible more accurate, scientific diagnosis, more intelligent prognosis, and more timely and effective treatment.

The writer wishes to express his grateful appreciation to Dr. Charles Lyman Greene for his careful

AURICULAR FLUTTER WITH FOUR TO ONE HEART-BLOCK

Auricular rate 244. Ventricular rate 61 (four "P" waves to each "R" wave), case of auricular fibrillation under Quinidine, passing to "flutter" (here shown), then to normal rhythm, and later relapsing into fibrillation.

criticism of this paper and his many helpful suggestions in its writing.

THE POLYGRAPH

This instrument consists of a double clockwork device which drives a narrow strip of paper under

the recording pens at a uniform rate of speed and simultaneously records the time in fifths of a second. One writing pen records the radial pulsations, the other the pulsations of the jugular vein,

Complete Heart Block

The auricles and ventricles are contracting regularly but entirely independently and at totally different rates. Note that the "P" wave, indicating auricular contraction, occurs at regular intervals and that the "R" and "T" waves, indicating ventricular activity, also occur regularly, but there is complete dissociation between them and the rate of the former is 75, while that of the latter is 66, an unusually rapid idio-ventricular rhythm. Usually the ventricular rate in complete block is 40 per minute or less.

Accurate diagnosis is possible only with instrumental methods of investigation.

as the record is usually taken. The normal tracing of the radial pulse consists of a series of single waves corresponding to the ventricular contractions. The normal jugular record is made up of a series of three chief waves for each radial pulsation, these waves being called the "a," "c" and "v" waves respectively. The "a" wave is produced by the systole of the right auricle; the "c" wave is due to the contraction of the ventricle, and the "v" wave reflects the distention of the large veins due to the accumulation of blood after the right auricle has become completely filled in diastole. The "v" wave is an evidence of stasis and is increased by all factors which tend to increase the amount of blood in the right auricle, such as high arterial tension, tricuspid regurgitation, etc. Variations from the normal in the character, time of occurrence and the sequence of the various waves readily defines any and all cardiac irregularities. Thus with an auricular premature contraction all waves of the normal cycle are present in their usual sequence, but all occur prematurely. With a premature contraction of ventricular origin, where the rhythm of the auricle is undisturbed, we find a premature and immature radial thrust, and in the corresponding jugular cycle the "c" wave precedes or occurs with the regularly occurring "a" wave. In a premature con-

traction of nodal origin, where the impulse arises in the auriculo-ventricular node between the auricles and ventricles, these two chambers contract at the same time and there is found in the jugular record an exaggerated wave, representing a fusion of both the "a" and the "c" waves, corresponding in time to the premature beat in the radial record.

In complete block there is no relation between the "a" waves of auricular contraction and the "c" waves of ventricular contraction and as in this condition the auricles contract more often than the ventricles, there are many more "a" waves than "c" waves in the jugular record. With partial block, where the ventricles respond to every second, third, fourth or more auricular contractions, in the first case or two-to-one block there are two "a" waves to each "c" wave; in the second case or three-to-one block there are three "a" waves to each "c" wave; and so on. In sino-auricular block where there is simply a temporary arrest of the heart action, we find normal heart cycles preceding and following the unusually long period of diastolic rest.

In auricular flutter the "a" waves occur at the rate of two hundred or more per minute, corre-

Right Branch Block

A grave condition which can be diagnosed accurately only by the electrocardiograph. Characterized by (1) exaggerated first and third leads; (2) notched and widened "R" and "S" waves; (3) the direction of the "T" waves in first and third leads, which is opposite in direction to that of the dominant wave of each.

The side through which the impulse passes is determined exactly as ventricular preponderance is determined. The block, therefore, must be in the opposite ventricle. (Third lead shows a left ventricular extrasystole.)

sponding to the excessive rate of contraction of the auricles, and as there is usually some degree of heart-block present, there are two, three, four or more "a" waves to each "c" wave. Paroxysmal

tachycardia in which there is characteristically a sudden outburst of rapid action of the whole heart with an abrupt ending, reveals itself in the polygram by these same features. The paroxysm begins and ends with a premature contraction, usually of auricular origin.

In auricular fibrillation the radial shows the total irregularity in rate, force and rhythm. The jugular record characteristically shows no definite "a" wave, but is completely over-run by coarse fibrillatory waves. The "c" waves, being due to ventricular contraction, also show a total lack of rhythm.

It should be said also, that in addition to its value in the accurate differentiation of the cardiac irregularities, the polygraph aids greatly in evaluating heart muscle strength, in showing the various grades of venous stasis, and in demonstrating variations in the conduction time of the heart. Again and again polygraphic findings are determining factors in the proper management of a heart case.

HOW TO CHOOSE A DOCTOR

Replying to an inquirer who wants to know how to be governed in the selection of a physician, Dr. Wm. A. Brady, in the *Chicago News*, gives the following pointers for the guidance of the layman in choosing his doctor:

First, the name of the good doctor is rarely seen in print.

Second, in making examinations he requires the patient to remove clothing which may interfere with the detection of signs and symptoms.

Third, when he is out of town he is attending a medical meeting or taking a brief postgraduate course.

Fourth, he asks frequently for consultations or refers patients to colleagues for special examinations, and when his patients die asks for autopsies, all because he never gets through studying medicine. This is why he buys so many books and subscribes to so many first class medical journals.

Fifth, he prescribes simple medicines to meet particular indications at the particular time, and not "ready-made" stuff with which he has recently been "sampled." Or, perhaps, he prescribes no medicine at all, but merely lays down some common-sense rules for the guidance of his patient.

Sixth, he never guarantees or promises a "cure," because to do so would be to be dishonest.

Seventh, he is invariably a stickler for the observance of the rules of ethics.

Eighth, being an honest laborer, he deems himself worthy of his hire and demands payment.

Ninth, he does not put a patient off with the evasion, "weak lungs," nor does he perpetrate the near diagnosis, "catarrh." He makes a definite diagnosis or frankly admits his inability to do so.

Tenth, "he will do anything short of murder for a loyal patient."

IRREGULAR ACTION OF THE HEART: ITS CLINICAL RECOGNITION*

CHARLES N. HENSEL, M.D.
St. Paul

Twenty-five years ago the chief interest in heart disease centered on valvular lesions and septic endocarditis. During the succeeding ten years the center of interest shifted to the heart muscle, and the capacity and integrity of the myocardium was stressed in all cases of heart disease. The last ten to fifteen years has witnessed an increase in our knowledge of the anatomical structure and physiological function of the heart. This knowledge has been manifest in a better understanding of the *conduction system* of the heart. By conduction system is meant that nervous mechanism lying within the heart itself which transmits contraction stimuli. It includes the sinus node in the wall of the right auricle where stimulus matter keeps accumulating and is discharged at regular intervals, causing contraction waves to spread over the auricles, as ripples spread from a pebble dropped into a still pool. These waves reach and stimulate a second node of nerve tissue, the auriculo-ventriculo- (or A-V node), lying on the floor of the right auricle. Impulses from the A-V node travel to the bundle of His (lying in the interventricular septum), down the bundle of His to the right and left branches which go to the right and left ventricles, the branches ramifying into a fine network of nerve fibres to all parts of the ventricles, called the arborization fibres, and ending in sensitive bulbous ends called the Purkinje system.

The vagus nerves join the heart largely in the sinus region and act as a curb to stimulus formation and discharge, in the sinus node.

The normal cardiac cycle consists of a definite sequence of events, namely, stimulus production and discharge, auricular contraction, ventricular contraction, diastolic pause.

Systole requires three-tenths of a second while diastole occupies five-tenths of a second. During all of systole and the early part of diastole all the functions of the heart except tonicity are in abeyance, therefore the heart is in a refractory state and cannot respond to stimuli. But as diastole progresses these powers return and by the time

*Read in Symposium on Irregularities of the Heart at St. Paul Clinic Week, January, 1924.

sufficient stimulus matter has accumulated at the sinus node to cause another contraction, excitability, contractility and conductivity have been restored.

Regular action of the heart depends therefore upon the normal balance between stimulus production at the sinus node, and *excitability*, *conductivity* and *contractility* of the heart muscle. Depression or exaltation of one or more of these functions will interfere with the normal sequence of events in the cardiac cycle and thus produce irregular action of the heart.

Schematic Drawing of Heart.
Showing Conduction System.

It is evident therefore, from the foregoing remarks, that the conduction system ranks equally with the myocardium in interest and importance to the cardiologist. The wider use of the electrocardiograph is the means by which there has come a better understanding of the conduction system and has made possible a more accurate differentiation of abnormal rhythms. The use of this instrument in the recent Great War with opportunity for the study of large groups of soldiers under constant supervision and control, has given a splendid correlation between instrumental and clinical findings. Subsequent observations in civil life have largely confirmed these observations, so that today in the majority of instances we are able to accurately differentiate *clinically* the various types of cardiac irregularities. This is particularly true

of the commoner and more important types under discussion.

Sinus Arrhythmia.—This type of irregularity is frequently seen while making an examination of an excited child. There is a rhythmic variation in heart rate, the heart speeding up with inspiration and slowing down with expiration. Probably unstable vagus control is responsible for this variable rate. Occasionally with the slow heart of convalescence following a severe illness we note this same rising and falling rate associated with respiration.

A rare form of sinus arrhythmia must be mentioned which occurs independent of respiration and in which there is a slowing and acceleration of the whole heart occupying ten to fifteen seconds and occurring at variable intervals. During the long pauses no abnormal heart sounds are heard. Anything which accelerates the heart (exercise, atropine, fever) abolishes this irregularity.

While sinus arrhythmia is found chiefly in childhood and adolescence it is also observed occasionally in adults of nervous or emotional temperament and is probably due to imbalance between sympathetic accelerative influences and vagus slowing influences. Sometimes it appears to be due to heavy indulgence in tobacco.

Extra-Systolic Irregularity.—Isolated extra-systoles are not difficult to recognize. The examining finger on the pulse detects a small beat occurring too soon in diastole, followed by a longer pause than usual. On listening to the heart with the stethoscope one hears three to four sounds, namely, the first and second sounds of the normal beat plus the sounds produced by the extra beat. If the extra-systole has not sufficient force to open the aortic and pulmonic valves then only three sounds are heard.

Patients may be unconscious of the occasional extra beat but frequently when extra beats become numerous they cause distress and anxiety, particularly in young, nervous, high strung individuals. These people experience a fluttering of the heart associated with momentary dizziness, and a sensation as though the heart had turned over and then stopped sometimes associated with precordial pain. During the diastolic pause they complain of a weird sensation of emptiness in the chest. If the extra-systoles are numerous and occur at short intervals the patients may feel ill and depressed.

Extra-systolic irregularity when marked may

have to be differentiated from auricular fibrillation and to do this a few short rules will suffice.

1. In extra-systolic irregularity there are always periods of normal rhythm.

2. The total heart rate is rarely above 120 beats per minute. An irregular rate greater than this is suggestive of fibrillation.

3. Exercise causes extra-systoles to disappear or to be greatly reduced in number.

4. In auricular fibrillation exercise increases the irregularity and causes the rate to rise.

Patients who are susceptible to marked extra-systolic irregularity occasionally experience times when the extra-systoles are not relieved or reduced by exercise, but instead the rate seems to rise, the heart to slam violently and a sensation of weakness and exhaustion supervene. This history is suggestive and if the patient is examined at this time he will, in all probability, be found suffering from an attack of transient auricular fibrillation.

Paroxysmal Auricular Tachycardia.—This consists of bursts of rapid regular action of the whole heart of sudden onset and sudden offset, due to an abnormal focus of impulse formation arising somewhere in the auricle outside the sinus-node. During the attack the new center dominates the movements of the whole heart, the influence of the pace-maker being temporarily lost. The heart at this time is but slightly under vagus control and such factors as emotion, exertion, rest or sleep, which materially affect the normal heart rate, do not modify the rate during an attack. Attacks may last seconds, minutes, hours, days, and may occur at varying periods for many years, the heart, during the free interval, in most cases showing no abnormalities. The rate during an attack may be anywhere between 110 and 200 per minute, the usual levels running between 140 and 190 per minute. Often paroxysmal tachycardia must be differentiated from the high rates in such affections as goiter, alcoholism and tuberculosis, but the presence of these diseases can be ascertained and the reaction of the heart to posture, exercise, and rest observed in differentiation.

Summary of Clinical Recognition.—If we find a patient in an attack of palpitation with (1) a history of previous attacks of palpitation of sudden onset and sudden offset; (2) with a heart rate of about 180 per minute and regular; (3) the rate unaffected by held breath, swallowing, change

of position, rest or exercise; (4) the rate unaffected or suddenly terminated by vagal pressure; and (5) the minute count constant from minute to minute, then in all probability we have a case of paroxysmal tachycardia. The minute count is obtained by counting the heart rate with the stethoscope over the apex for a full minute and repeating in five to ten minutes. In paroxysmal auricular tachycardia the minute count should not vary more than one or two beats, one beat where the second hand crosses the line at the start and one beat on the last second of the minute.

In borderland hyperthyroid states we sometimes observe attacks of palpitation of sudden onset but the offset is gradual, the rates dropping from around 160 beats per minute to 130 beats per minute to 120 beats per minute and thus resuming the patient's usual rhythm. In true paroxysmal auricular tachycardia the rate jumps abruptly between two beats to 180 or 190 or whatever the rate may be, stays at that rate for the duration of the attack and as suddenly between two beats resumes the usual rhythm.

Auricular Flutter.—This irregularity has been defined as that condition in which the auricles, due to new impulse formation outside the sinus node, are beating regularly at rates, varying in different cases, from 200 to 350 beats per minute. Flutter bears some resemblance to paroxysmal auricular tachycardia, but whereas in tachycardia each auricular contraction is followed by a ventricular contraction, in the high rates of flutter it is impossible for the ventricles to respond to all the auricular impulses so that some degree of block occurs, usually a 2 to 1 ratio obtaining, which means that two auricular beats occur to each beat of the ventricles. This degree of block is not always constant, but may vary from 2 to 1, to 3 to 1, or even 4 to 1 block. At times these ratios change from one rhythm to another, giving the heart an irregular action which might cause the condition to be confused with auricular fibrillation. However, this need not cause much trouble since in flutter there are always periods of regular rhythm, which rarely obtains in fibrillation.

Usually when flutter is first seen and especially should the attack come on in a paroxysm, the degree of block is a 2 to 1 ratio.

Certain fundamental points should be in mind when considering the possible presence of flutter,

namely, that while auricular tachycardia is relatively common and may occur all through life, flutter is a rare disturbance occurring in the middle and later years of life and is associated with signs of serious myocardial damage.

These patients with flutter usually give a history of previous attacks of palpitation of sudden onset for months or years, the present attack persisting. Examination reveals a regular ventricular rate between 130 and 160 beats per minute, which rate is unchanged by posture, rest, or exercise; is temporarily slowed by vagal pressure, but never stopped. The minute count is surprisingly constant from minute to minute.

Should there be any irregularity of the ventricular rate due to changing ratios of block, then a little exercise, namely, raising arm or leg from the bed, accelerates the ventricular action, induces perfect regularity of ventricular response (2 to 1 block) and then differentiation can readily be made. Should there still be any doubt clinically as to the presence of flutter then the total apex count is helpful.

Rates at the apex of 180 beats per minute or above must be auricular tachycardia, for to be flutter the auricles would have to be beating at least twice the counted rate or 360 beats per minute. This is so rare as to be negligible, the upper limits of auricular rate being as previously stated 350 beats per minute.

Finally, the termination of flutter is never sudden as in auricular tachycardia, but the condition is relieved by flutter merging into fibrillation and so back to the usual rhythm.

Auricular Fibrillation.—This is perhaps the commonest and most important of all the types of cardiac irregularity. It is marked by a disturbance in three of the fundamental functions of the conduction system, namely, impulse formation, irritability and conductivity.

The sinus-node, where normally stimulus matter regularly accumulates and is regularly discharged causing regular auricular contractions, has lost control, and from multiple areas over the auricular surface come rapid and minute twitchings and undulatory movements, but no definite systole of the auricle occurs, the auricles staying in diastolic standstill. These fibrillary twitchings of the auricular walls give rise to new pathologic impulses for contraction, similar to those shown to cause

single premature beats in extra-systolic irregularity. These numerous and haphazard impulses reach the A-V node, causing a profound disturbance in ventricular rhythm. The ventricular rate rises and contractions follow each other in a completely irregular manner. There occur short runs of small beats followed by large or small beats or by long or short pauses. This total lack of any dominant rhythm reminds one of the uneven gyrations of a freshly landed fish on the bottom of a boat.

The rate of ventricular response to these new stimuli depends on the soundness of the myocardium and the integrity of the conduction system. While the ventricles may, by excessive impulses, be stimulated up to 200 beats per minute, the usual rates in fibrillation, due to myocardial damage and conduction defects, lie between 90 and 140 beats per minute.

Many of the ventricular contractions have not sufficient force to open the aortic valves, so that these beats do not come through at the wrist, thereby producing a pulse deficit, namely, a difference in the number of beats counted over the apex of the heart with the stethoscope and the pulse rate at the wrist, the discrepancy often being 20 to 50 beats. For example, the rate at the apex might be 140 beats per minute while the rate at the wrist would total only 90 beats per minute.

While a pulse deficit does occur on other rapid rhythms, it is one of the suggestive differential points in auricular fibrillation. Due to the lack of auricular systole the ventricles are not completely filled, and this inadequate filling is further aggravated by the irregular diastolic pauses. Thus the systolic output of the heart is reduced and the flow and pressure in the coronary arteries is lessened, which latter further increases the myocardial debility.

The Murmur.—With fibrillation the presystolic rumble of mitral stenosis (the usual murmur) disappears, to be replaced by a long, low-pitched murmur beginning after the second sound. Because of the continual variation in the force of the heart there is variation in the intensity of the murmur, the murmur sometimes being absent because some of the beats are too weak to produce a murmur. While fibrillation, when once established, was formerly considered a permanent condition, now we have abundant clinical and instrumental proof that fibrillation may be of transitory nature, attacks

often coming on in a paroxysm, lasting a short time, followed by return to normal rhythm.

To summarize, the differential diagnosis is based on the following points:

1. A grossly irregular heart rhythm.
2. A heart rate moderately elevated from 90 to 140 beats per minute.
3. The presence of a pulse deficit is helpful but not pathognomonic.
4. The minute count varies at least three to five beats or even more per minute.
5. Vagal pressure slows the rate temporarily, but never stops fibrillation.
6. Change of posture accelerates the rate.

From the above points therefore it is generally not difficult clinically to differentiate fibrillation from auricular flutter and auricular tachycardia except where the heart rate is slow, namely, around 100 to 120 beats per minute. At these rates it may be confused with extra-systolic irregularity.

To differentiate these two we have only to remember that extra-systolic rates rarely rise above 120 beats per minute, that exercise reduces or abolishes extra-systoles, while it increases the irregularity and raises the rate in auricular fibrillation.

Before leaving this type of irregularity I wish to call attention to the association of fibrillation with goiter. This may be an accidental occurrence, since the fibrillation may have existed before goiter symptoms developed. But not infrequently fibrillation seems to develop as a result of the toxic action of the goiter and exists either as a continual state or occurring in transitory attacks preceding or following operation.

If the myocardium is healthy, relief of the goiter causes relief of the fibrillation in many instances.

Heart Block.—In this disturbance the conduction system is at fault. Impulses for contraction continue to be regularly formed as usual at the sinus node and regularly discharged at the normal rate. But after reaching the A-V node some or all of these impulses fail to be carried across the bridge of nervous tissue connecting auricles and ventricles, and there results *dropped beats*, *partial block*, or *complete block*, as the case may be.

The *dropped beat* is the first sign of incomplete conduction. When in a pulse previously regular

there is a long pause and one finds on listening to the heart that there is no sound nor movement during this pause (as occurs in extra-systole), nor any association with respiration as occurs in sinus arrhythmia, then the pause is probably due to a dropped beat from a failure of ventricular response.

As the degree of block increases, more and more beats fail to get across to the ventricle till finally the ventricle responds to only one-half the auricular beats and a 2 to 1 block is present. This is the usual type of partial block; while ratios of 3 to 1 and 4 to 1 do occur, they are uncommon. Suspect a 2 to 1 block when the ventricle beats regularly at rates between 40 and 50 beats per minute. If there is a sudden halving of the usual ventricular rate, suspect 2 to 1 block.

Complete Block.—In this condition *no* impulses get across to the ventricles and a complete dissociation occurs between auricles and ventricles. The auricles may beat as usual about 72 per minute, while the ventricle builds up a slow, regular, independent rhythm of its own at a rate of about 30 to 33 beats per minute. While not audible at normal rhythms sometimes the systole of the auricles can be heard during the long pauses of block as faint, muffled sounds. Also additional evidence of the contracting auricles can be seen by observing the regular rapid pulsations in the vessels of the neck.

Where heart block has become established some degree of ventricular hypertrophy is obligatory in order to obtain complete ventricular emptying. The diastolic blood pressure usually is low, due to the squeezing of the blood from the arteries into the veins during the long diastolic pauses. The systolic blood pressure is likely to be elevated to 160 to 200 mm. if the heart muscle is reasonably healthy to permit this adjustment.

Adams-Stokes' Syndrome.—In mild grades of block there often occurs giddiness, fainting or momentary loss of consciousness. These symptoms apparently may be caused by periods of temporary marked slowing of the ventricular rate, which may be reduced to a total of 20 beats per minute or even to 8 beats per minute. At times there may be single prolonged periods of from 3 to 15 seconds duration in which no ventricular systoles occur.

When either of the above conditions occurs, un-

consciousness supravenes, the patient's face and neck become livid, breathing becomes stertorous while twitching of the muscles of the face and upper limbs occur; but the tongue is not bitten nor urine voided. The above attack is called Adams-Stokes' syndrome. In apparent epileptic seizures with a ventricular rate constantly at about 30 beats per minute, one should always suspect heart block and Adams-Stokes' syndrome rather than epilepsy.

Alternation of Pulse.—This type of irregularity, characterized by a pulse regular in rate but uneven in force, and indicative of a myocardium overstressed nearly to the limit, is in the majority of instances impossible of recognition except by instrumental means. Rarely can the finger, palpating the pulse, detect the unevenness of alternate beats. If, however, the blood pressure cuff be applied and the radial pulse carefully palpated as the pressure in the armlet is increased, an alternation in the force of the beats, which was not appreciated before, becomes obvious as the smaller beats drop out and only the larger beats which are able to send an impulse to the wrist are detected.

There are no subjective sensations in this condition except those referable to the disease in which alternation occurs, namely, angina pectoris, senile hearts especially when associated with hypertension, and in some severe acute septic processes such as pericarditis and pneumonia.

In conclusion I wish to state that this endeavor at *clinical* recognition is in no sense an effort or desire to supplant such valuable aids as the electrocardiograph and polygraph, but disturbances of cardiac rhythm are often emergencies and sometimes serious, requiring immediate treatment when instruments may not be available.

Therefore, since, as has been shown above, the *clinical* recognition of many disturbances of cardiac rhythm is possible in the majority of instances, we should be prepared to differentiate these irregularities at the bedside or the operating table, leaving till later their exact verification.

Finally, I wish to acknowledge my indebtedness to the works of Doctors Thomas Lewis and John Hay, and to the writings of Doctors Samuel Levine, H. A. Willius and B. E. Hamilton, in the preparation of this paper.

TREATMENT OF THE CARDIAC ARRHYTHMIAS*

ERNEST T. F. RICHARDS, M.D.
Miller Hospital Clinic
St. Paul

We have seen from the preceding papers in this symposium that the frequently encountered irregularities of the heart-beat can be sharply defined and clearly recognized one from the other if all the agencies at our command are called upon in their investigation. As some of the arrhythmias are of the gravest significance and tax our therapeutic efforts to the utmost, while others are of little moment and do not require any special management, obviously, in the treatment of an irregular heart strict classification and correct interpretation are of the most fundamental importance. When these have been determined, the management of an arrhythmia is based on fairly well defined principles of treatment, the essentials of which only, of course, can be discussed here.

SINUS ARRHYTHMIA

This simple disturbance of rhythm need not detain us in a therapeutic discussion except to point out that its chief practical importance lies in its recognition in order that it may not be confused with one of the important irregularities. Depending on vagal tone, increased by deep breathing, and abolished by exercise, this type of arrhythmia obviously calls for no treatment. Unfortunately, though, it is not always correctly interpreted, and it is by no means uncommon to see children and young adults seriously cautioned against overdoing because of an "irregularity," when the rhythmical disturbance present is merely a heightened physiological response in a perfectly healthy heart.

EXTRA-SYSTOLES

Although frequently toxic or neurotic, the true cause of premature beats may often be in doubt, and the possibility of a damaged myocardium must always be kept in mind. For example, tobacco may in a given case be the exciting factor, but careful observation over a long period, together with electrocardiographic studies, may be necessary in order to determine whether the myocardial irritability is merely temporary and of little significance, or, on the other hand, is a permanent dis-

*Presented in symposium at St. Paul Clinic Week, St. Paul, January, 1924.

ability indicative of grave cardiac impairment. Again, the age factor, together with the incidence of acute infections and other intoxications, should always be given considerable emphasis in weighing the importance of extra-systoles.

Extra-systoles may, therefore, be of minor significance, requiring only the removal of the exciting cause, or, on the contrary, they may represent a seriously crippled heart. Thus, the premature beat of the student undergoing his final examination requires only reassurance and the completion of the ordeal; whereas, extra-systoles in the arteriosclerotic man of affairs demand an easing of the load on an impaired myocardium, a strict curtailment of the patient's responsibilities and activities, a régime of properly balanced rest, diet and exercise, and the eradication of all possible foci of infection.

Drugs play little or no part in the management of extra-systoles, but occasionally mild sedatives, such as the bromides, by inducing more relaxation and rest, are of distinct value. Quinine and quinidin, through their depressing effect on the myocardium, may abolish a troublesome premature beat which intrudes itself unpleasantly on the patient's consciousness, but we must not allow these agents to lull us into a false security, nor postpone a searching analysis of probable causes and of the true state of the myocardium. It is hardly necessary to add that a heart exhibiting extra-systoles should not have its irritability increased by the administration of digitalis unless, of course, its use is necessitated by a failing compensation.

In spite of the occasional presence of serious myocardial damage, as in elderly individuals and in those carrying a hypertension, our attitude toward this common type of arrhythmia may well be a decidedly optimistic one, as fortunately the great majority of hearts showing extra-systoles are structurally intact. One so frequently sees men in their prime condemned to a constant worry, either from being told by their physician that the heart is irregular, or from being conscious themselves of the irregularity, when reassurance and removal of the cause are all that are necessary to abolish the extra-systoles. Let me illustrate by citing one of numerous similar examples: An important business man of fifty, who showed numerous extra-systoles during a period of great mental strain with attendant loss of sleep and heavy smoking, was refused life insurance. Fear of sudden death from

heart disease added to his troubles, and incidentally to his extra-systoles. A short trip abroad returned him thoroughly rested and absolutely free from the arrhythmia. Now over a period of four years his heart has maintained a perfectly normal rhythm, he has been accepted as an excellent risk by the insurance companies, and he is pursuing a life of great activity in which physical exercise and relaxation share their proper proportion with the day's work.

PAROXYSMAL TACHYCARDIA

There is unfortunately no uniform treatment for this remarkable phenomenon. A slight paroxysm may terminate suddenly following some simple procedure such as tipping the patient up, or some other abrupt change in posture. Induction of vomiting, friction of the chest wall, or pressure on the vagus, may likewise terminate an attack. As, however, rapid cessation is an outstanding feature of this disorder, cause and effect are often in doubt.

Severe, prolonged paroxysms may resist all efforts and tax our resources to the utmost. Hypodermics of morphine, strophanthin intravenously, digitalis by mouth in full doses, quinidin sulphate intravenously, and chloral by rectum, are amongst the many procedures resorted to, but from the very nature of the disturbance one must always anticipate that results from any of these measures will be uncertain.

The experience of different observers varies widely in the results obtained by treatment in paroxysmal tachycardia. Digitalis usually has no appreciable effect, but Bernstein has reported a paroxysm of fourteen and a half days' duration which responded to full digitalization after resisting all other forms of therapy. Price believes that strophanthin, 1/100 grain intravenously, is the most useful remedy. Quinine has a strong advocate in Wenkebach, but in two recent cases in which we gave it in large doses during the paroxysms there was no effect. My personal observation has been that hypodermics of morphine, together with, if necessary, chloral by rectum, offer the most relief, probably by placing the patient in the most favorable condition for a termination of the paroxysm.

Paroxysmal tachycardia is compatible with long life. Death during an attack is infrequent, although it may occur if the duration of the paroxysm is greatly prolonged. Unfortunately, we

have no means by which we may correctly forecast the frequency of recurrences. There may be only one attack or, on the other hand, there may be several paroxysms in the course of twenty-four hours. It is, as a rule, a recurring disturbance but the intervals between paroxysms are extremely variable.

Between attacks diligent search should be made for possible exciting causes. Any existing gastrointestinal disorder should especially receive attention.

AURICULAR FIBRILLATION AND FLUTTER

Both of these conditions require full digitalization. In fibrillation, digitalis must be pushed to a point where the excessive impulses coming through the auriculo-ventricular bundle are sufficiently blocked to enable the ventricles to rest. In flutter, full digitalization is sought in the hope of converting the rapid, regular auricular rate into fibrillation and thence to a normal rhythm.

The brilliant results obtained in auricular fibrillation by digitalis have given to this drug its unequaled pre-eminence in the therapy of cardiac disorders. If enough of it is given to saturate the fibrillating heart, digitalis blocks auriculo-ventricular conduction and secures adequate rest for the ventricles. Similarly, in auricular flutter if digitalis is administered in amounts sufficient to profoundly depress conduction, thereby increasing the heart block, fibrillation of the auricles may follow and may be succeeded by a normal rhythm.

In securing adequate digitalis dosage a great advance has been made by Eggleston, Robinson and others, by using the body weight as a guide, but Withering's original directions are still true that "it should be given until it either acts on the kidneys, the stomach, the pulse, or the bowels." Eggleston has suggested 0.15 gm. of the leaf, equivalent to 1.5 c.c. of the tincture, for every ten pounds of body weight. Thus, by this method a man weighing 150 pounds would require 22.5 c.c. of the tincture for full digitalization. The experience of many, however, is that 0.1 gm. of the leaf, equivalent to 1 c.c. of the tincture, is sufficient for every ten pounds of body weight. Thus, in the 150 pound man, where rapid digitalization is required, as in auricular fibrillation, my usual practice is to administer a total of 15 c.c., given as follows: one-half of the total amount at the first dose, one-fourth after six hours, one-eighth in six

more hours, and the remaining one-eighth at the end of another six hours. The method is perfectly safe, as after the initial dose, succeeding doses may at once be discontinued if saturation is shown by a marked reduction in ventricular rate, or by the electro-cardiogram, or by toxic symptoms or coupled beats.

It is, I have found, more true of digitalis than of almost any other drug that the great mistake made in its administration is in giving it in too small and therefore ineffective doses. The great value of large and sufficient dosage is that complete saturation of a fibrillating heart can be obtained within a few hours, thus securing adequate rest for the ventricles. Furthermore, after saturation has been reached it must be maintained. The rate of excretion of digitalis in the adult amounts to 0.1 to 0.2 gm. of the leaf daily, the equivalent of 1 to 2 c.c. or 15 to 30 minims of the tincture. Therefore, it is necessary to administer at least this amount every day in order to maintain saturation when once it has been properly secured. Too much emphasis cannot be laid on this point, as by this means a fibrillating, badly crippled heart may carry on with a fair degree of efficiency for years.

Not since its introduction by Withering over 100 years ago has any drug been found which can surpass, or even approach, digitalis in the treatment of auricular fibrillation. Great interest, however, has recently been taken in the possibilities which quinidin sulphate possesses of bringing about a return to normal sino-auricular rhythm in some cases of auricular fibrillation. Almost a thousand cases of auricular fibrillation treated with quinidin sulphate have been placed on record since Frey, in 1918, advocated its use and recommended it in preference to quinine, which had been introduced into the therapy of auricular fibrillation by Wenkebach in 1914. While some observers are most enthusiastic over the results obtained, others issue serious warnings against the use of quinidin. When Lewis and his co-workers in 1921 showed that quinidin lengthens the refractory period of the heart muscle and slows conduction time, MacKenzie pointed out that the danger from the drug would lie in emboli following sudden restoration of sino-auricular rhythm. The report by Orr of embolic infarction of the brain occurring when normal rhythm was restored in a case of flutter, and several other cases now on record of embol-

ism following the administration of quinidin, have emphasized the importance of MacKenzie's warning. In spite of this possible danger, the majority of observers are agreed that in selected cases of fibrillation the employment of quinidin is justifiable in an attempt to bring about a restoration of normal rhythm. Its indiscriminate use is most certainly to be deplored, and especially in cases of long-standing fibrillation, or in fibrillation associated with decompensation, I feel most strongly that we are not justified in taking the risk of a possible fatal embolus through its administration. On the other hand, in fibrillation of recent origin, preferably of less than six months' duration, and in paroxysmal fibrillation, provided that the cases are kept under strict observation, I believe we have in quinidin a drug of unquestionable value. Numerous reports attest its merits. Thus, in twenty cases of auricular fibrillation reported by Clark-Kennedy, seventeen returned to a normal rhythm under quinidin. In Hay's fifteen cases, fibrillation was arrested in seven. Hewlett and Sweeney secured a return to normal rhythm in four out of eleven cases. In Hamburger's eighteen cases a normal rhythm was established by quinidin in eleven. These and similar reports show that normal rhythm has been restored by quinidin in 50 per cent or more of the cases in which it has been used. Such encouraging results, therefore, have in a selected case to be carefully weighed in the light of the known untoward results which have occasionally followed the employment of this drug.

When, after careful consideration, a case has been selected for quinidin therapy it is always advisable to test the individual reaction to the drug by first giving two doses of 3 grains each, from two to four hours apart. If these test doses have been well tolerated, from 15 to 30 grains a day, in divided doses, may then be administered until the rhythm becomes regular or until toxic symptoms appear. My experience has been that in the successful cases response to the quinidin usually occurs early, and that if by the fifth day a normal rhythm has not been established it is advisable to discontinue the drug. When a normal rhythm has been secured it may remain regular without the further administration of quinidin, other cases will require daily doses of 3 to 6 grains to hold the rhythm regular, while still others return to fibrillation in spite of the continuance of the drug.

Finally, in the management of these serious ar-

rhythmias, general measures, such as rest in bed, regulation of diet and restriction of fluid intake, are now procedures of such recognized value that they no longer need be emphasized.

HEART BLOCK

As arteriosclerosis plays such an important part in the production of bundle lesions, the treatment of most cases of auriculo-ventricular, branch, and intra-ventricular block is chiefly a question of rest and the enforcement of all protective measures which will relieve the crippled heart and arteries of unnecessary strain. Where, however, the existence of syphilis can be established, or in any case where there is the slightest chance of syphilis being a factor in the block, vigorous inunctions of mercury with large doses of the iodides should be pushed to the limit of tolerance. Under these measures a block may be abolished by the clearing up of a gumma or syphilitic infiltration in the bundle. Unfortunately, however, the outcome from such treatment is by no means certain and many cases which we have every reason to believe are due to syphilis fail to respond to even the most active treatment. Neosalvarsan in the syphilitic heart should, I feel, always be used with caution. Chief dependence should rest upon mercury and the iodides, but in a favorable case a small test dose of neosalvarsan may be administered and if unattended by any ill-effect may then be followed at intervals by other small doses. In cases of partial auriculo-ventricular block, especially where digitalis is suspected as a factor, atropin, by releasing the tonic action of the vagus, may be of decided value.

PULSUS ALTERNANS

The temporary alternation in the volume of the pulse occasionally seen in rapidly beating hearts, as in paroxysmal tachycardia and auricular flutter, is usually of slight significance. When, however, the contractile power of the ventricles has been so exhausted by myocardial degeneration that a persistent pulsus alternans is the result, the outlook is extremely grave and our chief concern must be to protect and relieve the heart in every way possible. Rest is the main essential in treatment. By lessening the exhaustion of the heart and relieving it from all strain, rest may sometimes restore a considerable degree of contractility even to a badly degenerated myocardium. Therefore, all measures to secure this end, including the free use of sedatives, must be sought.

In conclusion, let me emphasize again that a correct interpretation of its cause and significance constitutes the main platform upon which the treatment of an irregular heart is to be built; and that, although in some of the cardiac arrhythmias our therapeutic efforts are limited, there are others in which active measures of treatment, if carried out with sufficient thoroughness, lead to extremely satisfactory and even brilliant results.

EPSOM SALT PROTECTS AGAINST MOTHS

Epsom salt sprinkled in trunks, cupboards and other closed spaces is a great protection against moths, cockroaches and vermin and is considered preferable to the commonly used naphthalene by Dr. Paul Mitchell, Australian quarantine officer, whose recent investigations are told to us in the September *Hygeia*, popular health magazine (Chicago).

Dr. Mitchell noticed that on opening passengers' baggage for fumigation magnesium sulphate (Epsom salt) was sometimes used by travelers for the prevention of vermin. He determined to test its value as contrasted with naphthalene in the linen cupboards of the quarantine station, which was considerably troubled by the presence of moths, cockroaches, silver fish and a species of ant.

The cupboards were carefully cleaned out, the linen replaced and magnesium sulphate crystals scattered over the linen and shelves in one block, while naphthalene was used in another block. Weekly observations were made. At the end of three months traces of vermin were found in the cupboards where naphthalene was used, while those sprinkled with Epsom salt were free and the crystals of the salt as crisp as ever.

The difference in favor of magnesium sulphate was more noticeable at the end of five months, and by the end of a year the cupboards were still quite free from vermin, although the magnesium sulphate had deteriorated slightly, about a third of the crystals having turned to powder. These observations were confirmed by other trials. When tried in the open wards of the hospital, however, on mattresses, for example, the magnesium sulphate was found to deteriorate to a powder.

Dr. Mitchell concludes that Epsom salt is of far greater efficiency than naphthalene for the protection of linen and other fabrics against moths, cockroaches, silver fish, etc., but that on account of its rapid deterioration in the open it can only be employed in closed spaces.

STIGMAS OF LATE CONGENITAL SYPHILIS

PAUL A. O'LEARY, M.D.,

Section on Dermatology and Syphilology, Mayo Clinic,
 Rochester, Minnesota

My remarks will be limited to the characteristic changes in the structure of the body, which, when taken alone, warrant a diagnosis of syphilis, or should arouse suspicion leading to a diagnosis, irrespective of serology or history. Lawrence, in a statistical summary of the congenitally syphilitic children seen in New York State (exclusive of New York City) has called attention to the frequency with which these stigmas are overlooked, and confirmed the impression that the majority of the diagnoses are made because of the suspicion aroused by a history of parental infection or by the positive Wassermann report on parent or child.

The signs and symptoms which will be enumerated are those seen particularly in the child or adult who has passed through the early stages of syphilis acquired in utero, and who has managed to survive the acute phase of the infection. Such children may have had the "snuffles," or they may have had active cutaneous syphilis shortly after birth; but due either to their resistance or the low virulence of the invading organism, they have managed to survive this period, and may have reached puberty or adolescence before noting any serious effects from the infection. Many of these signs and symptoms are not manifested until later in life, when some accident, such as severe trauma, or a complication, such as pregnancy, or a superimposed infection, such as influenza, typhoid fever, pneumonia, or the exanthemas, lights up the latent syphilis. Fournier found that the average age at which the first subjective symptoms of late congenital syphilis appeared was twelve years, the ages ranging from three to twenty-eight years.

A discussion as to the mode of infection will be omitted, also as to whether the infection is paternal or maternal, whether the syphilis is acquired in the birth canal, and whether the spirochete itself, or some period in the life cycle of the spirochete, is the cause of the latency. It should be emphasized that in this series of cases 30 per cent of the patients had negative reactions prior to receiving treatment, and 60 per cent became Wassermann negative under treatment. More than half of the 30 per cent

showed clinical evidence of active syphilis in spite of the negative Wassermann reaction.

THE HUTCHINSON'S TRIAD

Perhaps the best known evidence of inherited syphilis is in the so-called Hutchinson's triad, the symptoms being eighth nerve deafness, interstitial keratitis, and Hutchinson's teeth. This triad was described by Hutchinson in 1863, and the symptoms are definitely pathognomonic. In various reports it is estimated that only 8 per cent of congenitally syphilitic children have the three manifestations, although a combination of either two, or one alone is often seen.

Fig. 1. a—Normal tooth, b, c, d—non-syphilitic serrations and notchings, e—Hutchinsonian incisor, converging edges (screw-driver shape), f—the Hutchinsonian incisor is a truncated cone, g—Typical Hutchinsonian tooth, pegged and notched, h—sagittal section showing anteroposterior thickening and notching.

Eighth nerve deafness.—Gradually increasing deafness in a young patient who has no local disease of the ear should arouse a suspicion of syphilis. The eighth nerve is one of the first to show clinical evidence of a syphilitic involvement, and it should be borne in mind that not only is the nerve itself the site of the reaction process, but that more frequently the appearance of the deafness means an active neurosyphilis with secondary eighth nerve involvement. The meninges are involved first, then the eighth nerve, and finally the labyrinth. Eighth nerve deafness may also be secondary to periostitis of the auditory osseus system. The number of congenitally syphilitic children examined who are deaf, varies, according to different observers, from 5 to 30 per cent. The deafness may appear early in life or not until maturity or puberty; it usually begins at the age of fourteen years, although cases have been reported at the age of forty-four years.

The onset may be gradual, with associated tinnitus, dizziness, and vertigo. Some consider a lowered bone conduction with a loss of the high tones of diagnostic value, although Goeckerman and

Barlow have shown that its value is questionable because 49 per cent of non-syphilitic patients examined had a definite reduction. If deafness develops late in life, labyrinthitis is commonly associated. Eighth nerve deafness may be the only involvement manifested in a family of congenitally syphilitic children.

The prognosis as the result of treatment is not very favorable unless treatment is started while the process is acute. Occasionally, in disease of this type the advance will be arrested and result in impaired hearing rather than in total deafness.

Interstitial or parenchymatous keratitis.—Interstitial or parenchymatous keratitis, which is seen in from 20 to 30 per cent of syphilitic children, is also an associated condition in from 2 to 10 per cent of patients with acquired syphilis. Zimmermann noted that interstitial keratitis was a symptom in 33 per cent of white male children, in 61 per cent of white female children, in 35 per cent of colored male children, and in 75 per cent of colored female children, with congenital syphilis,

Fig. 2. Typical Hutchinsonian upper central incisors.

although other reports vary from 6.5 to 96 per cent. Greene observed that nineteen of 100 patients had evidence of past interstitial keratitis. That girls

are more likely to have keratitis has been pointed out by several authors, and de Schweinitz mentioned the association of the onset of keratitis with menstruation. The onset, usually between the fifth and fifteenth year, is insidious, with ciliary congestion, photophobia, lachrymation, pain, and the appearance of a cloudy patch within the center of the cornea. Iritis, choroiditis, and retinitis may be associated. The two latter conditions are similar to those associated with acquired syphilis. Blood vessels derived from the ciliary vessels appear in the layers of the cornea, and produce the dull red color, or so-called salmon patch of Hutchinson. The presence of the minute straight blood vessels in the corneal scar, and the deposits in the retina and choroid after the acute process has subsided, may be a means of recognizing the inherited syphilis as the etiologic factor.

Fig. 3. Pseudo Hutchinsonian teeth. Examples of notching (traumatic) in a congenital syphilitic whose teeth are not of the true Hutchinsonian type.

The appearance of interstitial keratitis should be a warning that eighth nerve deafness may occur if vigorous antisyphilitic treatment is not given. The differential diagnoses of syphilitic interstitial keratitis and other types are based largely on the rec-

ognition of the associated stigmas and other clinical evidence.

Optic neuritis, optic atrophy, and extra-ocular paralysis are seen in association with congenital neurosyphilis, and present a picture similar to that

Fig. 4. Mulberry molar.

seen in acquired syphilis. Solomon quotes various statistics to show that between 0.4 and 0.63 per cent of all patients between the ages of eight and fifteen years with diseases of the eye have interstitial keratitis. Bilateral dacryocystitis may often be attributable to congenital syphilis.

Hutchinson's teeth.—These are one of the most valuable single diagnostic signs. The changes noted are in the permanent teeth only. According to various statistics, between 10 and 48 per cent of syphilitic children have one or more such teeth. The typical Hutchinson's tooth is peg or "screw-driver" shaped (Fig. 1, e), it is thickened anteroposteriorly (Fig. 1, f and h), is notched or grooved (Fig. 1, g), and the teeth are widely spaced. These characteristics are named in the order of their importance. The pointed tooth is not diagnostic unless among the upper central incisors (Fig. 2). The anteroposterior thickening is demonstrated in (Fig. 1, f and h). The grooving or notching is by no means as valuable a diagnostic aid as either of the two characteristics just described, but unfor-

tunately is the one so diligently searched for by those seeking to make a diagnosis of congenital syphilis. The most common change in the cutting surface of the tooth is the upward arching or grooving, the degree being dependent on the degree of pegging and anteroposterior thickening (Fig. 1, g). In other words, the more narrow the tooth, the more acute the arch or the grooving. The serrations and grooving noted in Figure 3 and Figure 1, b, c, d, may be seen in children who do not have syphilis, as well as in the congenitally syphilitic child. The spacing between the upper and lower central incisors is an additional diagnostic aid when associated with the other three characteristics. Single Hutchinsonian teeth are not uncommon, and may be of material aid in the diagnosis. Alapasia of the teeth, and particularly absence of the incisor teeth, should arouse suspicion. Stokes and Gardner have called attention to the value of x-ray examination of the teeth of children in whom the eruption of the permanent incisors is delayed. They demonstrated the unerupted Hutchinsonian tooth in a child who had been under anti-syphilitic treatment for four years before the x-ray examination was made.

Various other abnormalities in the incisors are seen occasionally, such as dwarfed or pointed lateral incisors, and loss of enamel on the lower third of the tooth, but these have no diagnostic value unless found in association with other clinical signs of the disease.

Besides the characteristic changes in the upper central incisors, sixth year molars may show similar changes. Attention was called to these teeth in 1870 by Moon, of England, and recently by Wall, of this country. The cutting surface of the tooth is worn, pitted and excavated. In this country it is called the mulberry or honey-combed molar, and is as common as the Hutchinsonian incisor (Fig. 4). An extra cusp, or the tubercle of Carabelli, on the inner side of the sixth year molars has been emphasized repeatedly by Sabouraud. In our experience it has been found not only in syphilitic children, but also in many normal healthy persons.

CUTANEOUS AND OTHER MANIFESTATIONS

The solitary gumma and the nodular syphiloderma.—The most common cutaneous manifestation of late congenital syphilis is the solitary gumma, and the typical nodular or tubercular syphiloderma, noted so often in patients with acquired syphilis,

may be seen occasionally in the congenitally syphilitic patient. The cutaneous gumma is usually the result of the extension of any underlying syphilitic process to the skin, but may be a solitary cutaneous involvement. The nodular syphiloderma with its characteristic, indurated, arciform border, and a tendency to peripheral extension, residual pigmentation, and atrophic scarring, is identical with the late syphiloderma of acquired syphilis. The so-called copper colored spots, supposedly the residue of an active syphilid, are of little diagnostic aid because, as a rule, such spots are not a result of syphilis.

Fig. 5. Classical facies of lues hereditaria tarda.

Scarring.—The scarring noted at the mucocutaneous junctures, known as rhagades, are valuable adjuncts. They are to be found most often about the mouth, eye, anus, and nares. The "spoke-like" character of the scarring is one of its salient points.

Lesions of the mucous membrane.—The lesions of the mucous membrane are of two types: the acute infectious mucous patch, and the late nodular gummatous ulceration. The former is seen in

the very young patient; the latter may be noted at any period of the disease. Syphilitic leukoplakia is rarely seen in these patients.

Visceral involvement.—The visceral involvement does not differ essentially from that of acquired syphilis, except in its insidious onset and slow progression. Hepatic syphilis, with which 14 per cent of our patients were affected, is the most common visceral complication, and cardiac syphilis among the rarest.

Facies.—Not all congenitally syphilitic children present the classical textbook facies characteristic of congenital syphilis, but when they exist, they are usually recognized at sight. In fact, there is an erroneous tendency to attribute to syphilis all conditions that cause a "saddle-back nose," the paramount change in the congenital syphilitic facies. The characteristics of the pronounced facies seen in Figure 5 are due to the destruction of the septum, the prominence of the frontal bosses, the high forehead or so-called Websterian dome. The prominence of the lips and peg-shaped head are also contributory. When the nasal septum is intact there may be either no deformity or only a slight depression of the nasal bridge. In this type the forehead and prominent frontal bosses are sufficient to stimulate one to search further for other stigmas.

Lesions of the bones.—The lesions of the bones in congenital syphilis are valuable aids in its diagnosis. The most common lesions noted are saber-shin, periostitis, osteochondritis (epiphysitis), dactylitis, osteitis, and lesions of the joints.

The so-called saber-shin, or the anterior bowing and lateral thickening of the tibia, is a valuable sign (Fig. 6). The underlying process, which may be either a bone blister or a subperiosteal gumma that has become calcified, is, as a rule, symptomless, although occasionally an acute process may light up with symptoms of pain, particularly at night, swelling, heat, and marked tenderness. The distinction between the anterior bowed tibia of syphilis and the lateral bowed leg of rachitis must be borne in mind. The former is associated with definite lateral thickening of the tibia besides other evidence of syphilis, while the latter is associated with lesions of the tibia and fibula, and clinical evidence of rickets.

Congenital syphilitic periostitis, when acute, presents essentially the same findings as acquired

syphilitic periostitis: pain, tenderness, swelling, and nocturnal pain, but in the chronic type, thickening and bowing are the only signs, the roughening of the anterior edges of this tibia not having much diagnostic value.

Fig. 6. Saber tibia.

Osteochondritis or epiphyseal enlargement is a common complication. When it occurs in the wrist it is the cause of ulnar deviation or the spreading of the fingers to the ulnar side when fully extended. Enlargement of the elbow and knee-joints may be noted also.

Dactylitis, the fusiform swelling of the shaft of the phalanges, may be noted in syphilitic and tuberculous children. The pathologic process, according to the x-ray, may be either osteitis or osteomyelitis. Syphilitic dactylitis is usually single, most often involving the index finger, while tuberculous dactylitis is invariably multiple.

Osteitis and osteomyelitis, with or without associated periostitis, present no particular characteristics, and other stigmas of the disease must often be sought before the causative factor can be determined.

Hydroarthritis, or glutton's joints,^{4, 5} is a painless bilater hydrops due to inflammation of the synovial membrane, involving as a rule only the knee-joints. The von Gies joint, or osteoarthritis, is a progressive multiple chondritis occasionally encountered in the syphilitic child.

Graves called attention to the scaphoid or winged scapula, in which there is a convex curvature of

the vertebral side of the angle. Syphilitic Pott's disease has also been observed not infrequently.

Lesions of the nervous system.—The nervous system is involved in much the same way as in acquired syphilis. The more common forms of neurosyphilis are epilepsy, tabes dorsalis, paresis, taboparesis, paraplegia, diplegia, hydrocephalus, and cerebrospinal sclerosis. Parker, in a report of seven cases of juvenile tabes, noted that the clinical findings were quite similar to those recorded in cases of the acquired type of neurosyphilis, differing, however, in the insidious onset and latent course of the disease, the frequency of incontinence, and optic atrophy. He observed that ataxia, girdle pains and lightning pains were very rare.

In this group of late congenitally syphilitic children only 14 per cent had definitely positive spinal fluid findings, whereas Jeans has reported 32.7 per cent, and Kingery 28.8 per cent. The difference may be attributable to the fact that in my series, the borderline or questionably positive spinal fluid findings were not regarded as positive. The average age of onset of clinical symptoms of congenital neurosyphilis is about fifteen years. Hydrocephalus, paraplegia, and diplegia due to syphilis are rare. Mental retardation and idioey are often met with as complications. Higgins reports that 42 per cent of mentally defective children had positive Wassermann reactions, and Jeans found that twelve of twenty-five neurosyphilitic children were mentally defective. In spite of these figures we frequently see the congenitally syphilitic child who is decidedly precocious and above his age average mentality. Hypertrichosis in the brunette, and the "syphilitic mop" are contributory findings. Leontiasis ossei, chronic peritonitis, intestinal bands and kinks, pulmonary lesions, nephritis, both acute and chronic, Raynaud's syndrome, Banti's disease, and aleukemic lymphadenosis have all been reported by various writers as attributable to congenital syphilis.

CONCLUSIONS

1. The classical stigmas of congenital syphilis are described, Hutchinson's triad being the most prominent.

2. Statistics are given as to the frequency with which certain of the stigmas are found. However, any deduction drawn from the percentages given would be misleading because it is not uncommon to find but one diagnostic stigma in a congenitally syphilitic child.

3. The serologic findings in this group have been particularly emphasized in order to impress on the reader the fact that, if only the Wassermann test of the blood is depended on for the diagnosis, only 70 per cent of the cases of late congenital syphilis will be correctly diagnosed.

4. Neurosyphilis was revealed in only 14 per cent of the children examined serologically, in contrast to 32.7 and 28.8 per cent as reported in the literature.

5. Attention is called to the need of corroborative aids, such as examinations of the eye and ear, x-ray examinations, and serologic tests in certain of these patients.

INTRAPERITONEAL TRANSFUSION WITH CITRATED BLOOD: A FURTHER CLINICAL STUDY*

DAVID M. SIPERSTEIN, M.A., M.D.

With the technical assistance of
Miss Anna L. Kvenberg

Minneapolis

INTRODUCTION

The therapeutic benefits to be derived from blood transfusions are well recognized. The introduction of sodium citrate solution, with the consequent development of our present-day technique, has made transfusion a fairly common and relatively simple procedure. Until recently the importance of blood transfusions in infancy has not been fully appreciated. The introduction of the sinus route by Helmholz in this country, opened a new field in pediatric therapeutics.

However, an important period of life, during which the anterior fontanelle is closed and direct exposure of a vein difficult or impossible, was overlooked. Furthermore, while sinus puncture to the trained and well equipped man is a relatively simple procedure, it is not without inherent dangers. Many men have pointed out the difficulties frequently encountered, due to anatomical variations, to previous trauma, or to technical considerations of the moment. Under these conditions, and especially during the first period of childhood, a method of transfusing blood became essential.

Direct intravenous transfusion is obviously impractical, except through the jugular vein. The introduction of blood through the jugular vein is, however, limited in its scope to a comparatively few men of sufficient experience and training. Individual aptitude for any special technical procedure cannot apply to the profession at large.

The only other route that affords any possibility of success is the intraperitoneal one.

REVIEW OF PREVIOUS DATA

a. Animal Experimentation.

Since the work of Von Recklinghausen, in 1862, numerous investigators have shown that the peritoneal cavity of animals is capable of marked absorptive powers. All of the work was done with whole blood or defibrinated blood. Ponfick, in 1875; Poncet, in 1879; Arloing and Tripier, in

1880; Hayem, in 1884; Wm. Hunter, in 1887; Southgate, in 1897; Lesage, in 1900; Buxton and Torrey, in 1906; and Zimmerman in 1921,[†] are among the outstanding observers who have carried on investigations in this field. These men showed, through various more or less ingenious methods, that blood is absorbed from the abdominal cavity.

In a previous communication, Siperstein and Sansby² have shown the value of using citrated blood. From a study of a fairly extensive, controlled series of experiments, we were able to show that freshly citrated blood is absorbed very rapidly from the peritoneal cavity of rabbits. We concluded from our study on animals that the intraperitoneal route for blood transfusions was a justifiable procedure, safe in application, practical in results, and deserved a clinical trial.

b. Clinical Experimentation.

As far as we have been able to determine, Ponfick, in 1875, was the first one to inject defibrinated blood into patients. His results were apparently favorable. Buresi, Golgi and Raggi, Scottini, Giovanni, Liegl, and others, used this method, about the same time, without striking effect. The intraperitoneal injection of defibrinated blood then fell into disuse.

Our own studies, however, with citrated blood encouraged us to attempt its clinical application. Complete data and results obtained have been published elsewhere³. It may be stated, in brief, that we felt justified, from the therapeutic effects obtained, in continuing this procedure in other cases.

MATERIAL AND METHODS

It is our purpose in this paper to discuss intraperitoneal blood injections in general and to present other clinical cases. Furthermore, we are able to report several cases showing the limitations of this method.

Our clinical diagnoses in the cases to be presented are:

- Case 5. Secondary anemia. Hemolytic anemia.
- Case 6. Purpura hemorrhagica.
- Case 7. Athrepsia.
- Case 8. Streptococcic meningitis.
- Case 9. Pyloric stenosis.
- Case 10. Prematurity. Lues.

A routine method of procedure is followed. The recipients' and donors' bloods are grouped before

*From the Department of Pediatrics, University of Minnesota. Read before the Consulting Medical Staff of the Lymanhurst School for Tuberculous Children, Jan. 23, 1923.

[†]A complete review of available literature was given in a former paper.

every transfusion. The usual precautions regarding the donors' blood are always taken.

On the morning of the transfusion the patient is not given any breakfast. Freshly prepared 2 per cent citrate solution is used in the customary proportion of 10 c.c. of citrate solution to 100 c.c. of blood. The donor's blood, kept at body temperature and strained through gauze, is *immediately* injected into the peritoneal cavity of the patient. The abdominal puncture is performed in the usual manner.

It is necessary to emphasize only two points in the entire procedure. The citrate solution must be fresh and the donor's blood must be injected immediately.

For forty-eight hours following each transfusion all specimens of urine and feces are tested for blood. Benzidine and guaiac tests are used. In addition, the temperature of the patient is taken every two hours until the reaction, if any, has subsided (Figs. I and II). Hemoglobin estimations, red blood cell counts and blood smears are in some instances taken every hour on the day of transfusion, then at least once daily during the subsequent stay in the hospital. Unless otherwise stated, all hemoglobin determinations are made with the Fleischl-Miescher hemoglobinometer. All the blood counts are made by the same person, ruling out individual variations in technique.

Fig. 1. Graphic presentation showing temperature reactions following intraperitoneal transfusions.

CASE REPORTS

CASE 5. (H7356)—Secondary Anemia (?) Hemolytic anemia. Patient, five months old, admitted to the hospital Dec. 11, 1922, complaining of pallor, listlessness and poor appetite. When two weeks old, the baby suddenly "turned yellow" and commenced to vomit. A doctor was called, who found a marked secondary anemia (hemoglobin 20 per cent; red blood cells 1,472,000). The baby was given whole blood subcutaneously several times without marked effect. The sinus route was then resorted to with

better result. A third attempt at sinus transfusion was unsuccessful. Direct exposure of a vein in the arm was also unsuccessful. The baby was then given citrated blood intraperitoneally a number of times with apparent success. The transfusions were discontinued when the hemoglobin reached 59 per cent.* Two weeks after the last transfusion, the hemoglobin began to fall. Medical advice was not requested until December 9, 1922. At that time, the hemoglobin was 28 per cent.

Physical examination showed a well developed, well nourished infant, apathetic, irritable, with a marked pallor and slightly yellow tinge to skin. The spleen was palpable 6 cm. below the costal margin.

Fig. 2. Graphic presentation of temperature reactions following intravenous transfusions.

Laboratory Data on Entrance.—The urine examination was negative and there was no urobilin or urobilinogen present. The stools were repeatedly negative for blood. The blood picture showed a hemoglobin of 35 per cent (Von Fleischl-Miescher); red blood cells 1,300,000; white blood cells 31,200 with a differential count of polymorphonuclears, 24 per cent; lymphocytes, 88 per cent; transitionals, 6 per cent; and eosinophiles, 2 per cent. The Wassermann reaction was negative. The parent's blood test was also negative. The bleeding and clotting time was within normal limits. The fragility test was normal. The patient was in Group IV. Morphological examination showed deeply stained red cells; marked anisocytosis, many nucleated erythrocytes; polychromatophilia—evidence of active bone marrow stimulation.

Subsequent Notes.—Dec. 11, 1922. Intraperitoneal transfusion with 100 c.c. of citrated blood. Temperature reaction—103 degrees. (Fig. 1.) No occult blood in urine or feces.

Dec. 13, 1922. Intraperitoneal transfusion with 100 c.c. of citrated blood. Slight temperature reaction. Gradual improvement in blood picture.

Dec. 15, 1922. Color of skin and general condition is improved. No urobilin or urobilinogen in the urine.

Dec. 18, 1922. Intraperitoneal transfusion with 100 c.c. of citrated blood. Blood picture apparently normal mor-

*This case was reported in detail in a previous communication.

phologically. No change in size of spleen. Urine and feces negative for blood.

Dec. 29, 1922. General improvement with gain in weight. Spleen barely palpable. Duodenal contents shows no urobilinogen and 2,816 degrees urobilin.

Jan. 2, 1923. Duodenal contents shows no urobilinogen and 1,720 degrees urobilin.

Jan. 7, 1923. The blood picture has remained fairly uniform since the last transfusion. There has been a steady gain in weight.

Jan. 11, 1923. Blood values have dropped the past few days. The hemoglobin is 63 per cent; the red blood cells—3,450,000.

Jan. 12, 1923. Intraperitoneal transfusion of 150 c.c. citrated blood. Donor and recipient were cross-grouped. No occult blood in urine.

Jan. 15, 1923. Physical examination shows patient in good condition. Spleen palpable 3 cm. below costal margin.

Jan. 29, 1923. Dispensary note: Examination negative. Patient is active and contented. Weight 6,950 grams.

Subsequent course and treatment are given in Table III, and in an earlier communication.

Dr. H. S. Lippman was requested to examine the blood smears of this patient. As a result of his study, he allows me to present the data obtained by him. (Table I.)

The following summary has also been prepared by Dr. Lippman:

"Throughout the case the bone-marrow is reacting well as evidenced by large groups of platelets, slight leucocytosis, and red cells which appear when bone-marrow is stimulated, anisocytosis, polychromatophilia, and nucleated red cells. Naked erythrocytic nuclei are also present in the first few smears and these are definite evidence of bone-marrow hyperactivity.

"The lymphatic hemopoietic tissue also shows evidence of increased stimulation by the plasma cells, Rieder cells, and increased number of lymphocytes."

Blood transfusion was urgent in this case. Evidently the efforts of the bone-marrow to regenerate a sufficient supply of cells could not cope with the apparent destructive process taking place simultaneously. Every method of giving blood had already been used. After the present admission into the hospital, three intraperitoneal transfusions at short intervals were sufficient apparently to restore the blood picture to normal (Table II). The rapid improvement of the general condition and of the blood picture in particular were very gratifying. It is interesting to note that this patient has received over 1300 c.c. of blood intraperitoneally. What is the fate of the injected blood? Any theory other than that of absorption is difficult to interpret. The rise in blood values and the clinical effect on the patient are indicative. The disappearance of evidence of bone-marrow stimulation following the transfusions also points to absorption of the cells. It has been shown that the bone-marrow ceases to function when the body possesses too much blood, for example in animals made plethoric by transfusions⁴.

CASE 6 (H6653).—Purpura hemorrhagica.

History.—A boy, three years of age, was admitted to the hospital Nov. 9, 1922, complaining of bleeding from the right eye and ear, nose and throat and small "bluish spots"

TABLE I
Comparative Data Showing Differential Blood Counts and Morphological Changes
(Dr. H. S. Lippman)

Date	Hgb. %	R.B.C.	W.B.C.	P.M.N.	Lymph.	Nucleated R.B.C.	Remarks
Dec. 11, 1922	35.0	1.3	31,200	40.5	49.0	9 per 100 W. B. cells	Occasional Rieder and plasma cell. Good bone marrow reaction.
Dec. 15, 1922	54.6	2.8	16,400	44.0	47.5	8 per 100 W. B. cells	Good rise in hemoglobin and erythrocytes. Less evidence of lymph-node irritation.
Dec. 18, 1922	54.6	3.2	11,500	24.5	71.0	12 per 100 W. B. cells	Bone-marrow reaction continues. Rise in lymphocytes probably relative.
Dec. 20, 1922	59.5	4.25	10,600	26.0	68.5	3 plasma cells.
Dec. 23, 1922	70.0	4.24	36.5	59.0	½ per 100 W. B. cells	Practically no nucleated red cells. Slight anisocytosis. Red cells almost normal.
Dec. 30, 1922	66.5	3.84	14,400	26.0	67.0	½ per 100 W. B. cells	No change.
Jan. 4, 1923	70.0	4.09	13,000	36.0	55.0	0 per 100 W. B. cells	Normal smear.
Jan. 10, 1923	66.0	3.97	12,600	24.0	70.0	0 per 100 W. B. cells	Normal smear.

over entire body. The mother had noticed blue spots all over the child's body on November 8, 1922. On the day of admission the patient began to bleed from the right eye and ear. There was also an active hemorrhage from the nose and mouth.

Physical examination showed a well developed, well nourished, very listless patient with purpuric spots over entire body and blood oozing from the eye, ear, nose and throat.

There was active bleeding from the mucous membrane of the throat. The heart showed a systolic murmur at apex and base, which was not transmitted. The spleen was not palpable.

Laboratory Data on Entrance.—The urine showed a trace of albumen, numerous hyaline, granular, and waxy casts and many red blood cells and pus cells. The blood examination showed a hemoglobin of 65 per cent (Tallquist); red blood cells, 3,900,000; white blood cells, 10,200—with a normal differential count. The platelet count was 35,000.

The patient was in Group III. The bleeding time was over three hours; the clotting time 30 min. (?).

Subsequent Notes.—November 9, 1922. Within two hours after admission to the ward the patient received 200 c.c. of citrated blood (Group IV) intravenously. The median basilic vein was exposed and transfusion performed. Immediately following the transfusion, the routine post-operative procedures were put into effect.

Nov. 10, 1922. Patient showed a slight temperature reaction, 102.2 degrees. Active hemorrhage started again at 2:30 A. M. and at 9:00 A. M. the pulse was barely perceptible. The median basilic vein of the other arm was exposed and 450 c.c. of citrated blood was introduced. Moderate hemorrhage followed the second transfusion. Bleeding stopped completely several hours later.

Nov. 11, 1922. No hemorrhage. Much improved.

Nov. 15, 1922. Intraperitoneal transfusion with 70 c.c. citrated blood. All specimens of feces were negative with

the benzidine and a negative guaiac reaction. Other specimens were negative.

Nov. 16, 1922. General condition good. Purpuric spots beginning to fade.

Nov. 18, 1922. Given 300 c.c. citrated blood intraperitoneally. Moderate temperature reaction. No subjective symptoms. Urine and feces specimens were negative for occult blood.

Nov. 21, 1922. Gradual improvement. Purpuric rash almost gone.

Nov. 22, 1922. Intraperitoneal transfusion with 200 c.c. citrated blood with no temperature or pulse reaction.

Dec. 6, 1922. The patient is improving daily. The blood picture is normal.

Dec. 12, 1922. The tonsils and adenoids have been removed with only a moderate reaction.

Jan. 25, 1923. Dispensary note. The patient is in excellent condition.

Upon entrance into the hospital, the only mea-

sure considered was an immediate intravenous transfusion. This was done twice to overcome the acute condition. The virulence of the infecting agent can be realized if one considers that, after the intravenous introduction of 700 c.c. of blood (the total blood volume of the patient is approximately 1000 c.c.), the blood values were 30 per cent hgb., 1,656,000 red blood cells respectively. After the hemorrhage was stopped, the intraperitoneal method was utilized to hasten recovery. Data available and results obtained are shown in Table III.

POST-MORTEM STUDIES

The opportunity to examine the peritoneal contents of patients who have received transfusions is limited. Evidence of blood absorption and of blood destruction through indirect methods are neces-

sarily subject to criticism. Methods available at the present time are not satisfactory. Consequently direct observation is the only certain way of determining whether blood is absorbed from the abdominal cavity. Observations of this character are few in number. Opportunities for study following injury of some organ in the abdominal cavity, while more numerous, present problems not directly comparable with those resulting from intraperitoneal transfusions. The following cases are reported in an attempt to gain more direct and accurate data upon this question.

CASE 7 (H7287).—Athrepsia.

A girl aged seven weeks was brought into the hospital Dec. 7, 1922. The complaint was undernutrition. The physical examination showed marked underdevelopment and dehydration. The weight on entrance was 2,060 grams. There was very little improvement in her condition during the week following her admission. She was given a sinus transfusion of 60 c.c. citrated blood, but there was no rise in blood values.

Dec. 18, 1922. Weight, 2,300 grams. Feeding changed from Czerny's butter-flour mixture to casein milk because of a developing diarrhea.

Dec. 20, 1922. Given 100 c.c. citrated blood intraperitoneally.

Dec. 23, 1922. Sudden cyanotic attack with labored respiration. Temperature 97 degrees F. There is evidence of bronchopneumonia in the right lower lobe. The patient died two days later.

Post-mortem findings showed 50 c.c. of thick, viscous blood in the peritoneal cavity. There were no clots, adhesions or evidence of peritonitis. There was a massive bilateral bronchopneumonia.

CASE 8 (I-33).—Streptococcic meningitis.

A girl aged ten months was brought into the hospital January 2, 1923, complaining of cough, fever, and fretfulness of four days' duration. The physical examination showed an apathetic infant with a markedly bulging anterior fontanelle; neck rigidity; median strabismus; *tâche cerebrale*; and a positive Babinsky and Kernig. The urine examination was negative. The leucocyte count was 18,000. The spinal fluid was milky and under increased pressure; the Nonne was positive; cell count 7,700 cells per cu. mm. and smears showed numerous streptococci.

Jan. 4, 1923. Spinal fluid shows 43,000 cells per cu. mm. The patient is moribund. She was given 100 c.c. of citrated blood intraperitoneally at noon and died twelve hours later.

Post-mortem findings showed apparently no absorption. The smears of the abdominal contents showed unchanged red blood corpuscles.

CASE 9.—Service of Dr. Max Seham. A boy, seven weeks old, admitted to hospital care Jan. 7, 1923, because of persistent vomiting and loss of weight. The present illness started January 1, 1923, with projectile vomiting. The fluid loss was replaced by rectal and intraperitoneal injections of saline. On January 19, the abdomen was

opened under local anesthesia and a Rammstedt operation performed.

Immediately following the operation, food was retained for longer periods, but vomiting continued. Intraperitoneal blood was given thirty-six hours before death (January 21, 1923).

The post-mortem showed approximately 80 c.c. of fluid and clotted blood in the peritoneal cavity.

CASE 10 (I-3997).—Prematurity athrepsia, lues.

A two months' premature baby girl was admitted to the hospital because of failure to gain in weight and constipation. The baby had been breast fed the first two weeks of life and then placed on Borden's Eagle Brand condensed milk without showing any gain. On entrance, the weight was 2,170 grams. Physical examination showed an extremely emaciated, dehydrated infant.

The laboratory findings showed an essentially negative urine. The blood picture was 38.5 per cent hemoglobin; 2,600,000 red blood cells; 23,200 leucocytes with 46 per cent polymorphonuclears and 50 per cent lymphocytes. The Wassermann reaction was repeatedly positive.

For two days after the entrance the baby received normal saline intraperitoneally (125 c.c. b.i.d.). On the third day, it was given 75 c.c. of citrated blood intraperitoneally. There was no reaction. Its weight gradually increased to 2,790 grams and she appeared somewhat improved. On the third day, the course became rapidly worse. The patient died six days after the transfusion.

At the post-mortem the peritoneal cavity was perfectly clean and showed no trace of blood. There were no clots, adhesions, or evidences of peritonitis.

An analysis of our post-mortem results is of interest. In order to present them more clearly we have tabulated the data obtained (Table IV).

These results indicate clearly, in our opinion, that, in these cases, we may have a contraindication towards the intraperitoneal injection of blood. While the post-mortem findings have failed to show any evidence of harm resulting from the procedure they have shown that its value is questionable in this type of case. The clinical condition of these patients must be considered. At the time of the transfusion all physiological processes were undoubtedly slowed. However, if absorption does not take place within a reasonable period in cases of athrepsia, the intraperitoneal route is not justified. Its value, we believe, is directly proportional to the rapidity of absorption of the blood from the peritoneal cavity.

DISCUSSION

a. Puncture of the Peritoneal Cavity.

The introduction of a needle into the abdominal cavity, while theoretically fraught with danger, has been shown by numerous observers to be safe practically. With the proper training and precautions,

abdominal puncture is harmless. The introduction of saline and glucose solutions into the peritoneal cavity is done almost routinely in many pediatric centers without ill effects. The popularity of the method and its harmlessness are attested to by the abundant literature on this subject. We recently had the opportunity of observing two cases at post-mortem, who had received 25 to 50 intraperitoneal injections of normal saline respectively. There was

no evidence of peritonitis or adhesions in either case.

b. Value of Blood in the Peritoneal Cavity.

In a previous paper we have shown, in some detail, the importance of blood in the abdominal cavity. We pointed out that patients suffering internal hemorrhages recover much more rapidly than others who lose an equivalent amount of blood externally. We also emphasized the significant fact

that auto-transfusion and retransfusion of blood obtained from the peritoneal cavity is being used successfully.

Free blood in the abdomen has been shown to be harmful because of the danger of clots with the subsequent formation of adhesions. For obvious reasons, the presence of citrated blood has not been, as yet, proved harmful. Available data obtained at post-mortem would tend to show that its presence in the peritoneal cavity is without ill effect. We are at present engaged in a histological study of available clinical cases and hope to report the results obtained later.

c. Absorptive Power of the Peritoneal Cavity.

We realize that the application of animal experimentation to human beings has its limitations. However, it is felt that a thorough discussion and a careful clinical application may be of practical importance.

A careful review of the literature shows that we have undoubtedly under-estimated the absorptive capacity of the abdominal cavity and, furthermore, have to a large extent failed to avail ourselves of this property, and utilize this knowledge.

The mechanism involved is of considerable importance. Von Recklinghausen, Notkin, Beck, Muscatello, Meltzer, MacCallum, and others support the lymphatic theory of absorption. On the other hand, men like Starling and Tubby, Hamburger, Mendel, Dandy and Rowntree favor the blood-vessel theory of absorption.

Later evidence favors the lymphatic theory. It has been shown repeatedly that the lymphatics of the diaphragm play a very important rôle in the process of absorption. Cunningham⁵, in a very thorough and conservative paper, has recently made the following statement: "The results of my own experiments indicate that most, if not all, of the transfer of granular material from the peritoneal cavity into the diaphragmatic lymphatics, during the first 30 min., takes place by means of a type of phagocytosis. That later on leucocytes do bring in loads of granules is undoubted, but it seems very likely that the large inflow of free granules continues so long as any remain free in the peritoneal cavity."

Rate of absorption, for obvious reasons, can only be estimated by indirect methods. We have shown that rabbits can absorb one-fifth of their total blood volume in approximately three hours. It may be assumed for the present that many factors are involved. The general condition of the patient; the amount of blood transfused; the number of transfusions already given; the interval between transfusions; the condition of the donor's and recipient's blood; the rate and depth of respiration; the movements of the diaphragm; the intra-abdominal pressure; and possibly many other factors are of importance. Bolton⁶ has shown that movements caused by artificial respiration were sufficient to force materials from the peritoneal cavity into the lymphatics of the diaphragm of animals dead for

TABLE IV

several hours. The possible importance of auto-agglutinins and isoagglutinins in the blood may deserve consideration.

At the present time, the only means of estimating rate of absorption are the temperature curve and the repeated blood examinations. Their value is of course doubtful from a scientific standpoint. However, we are inclined to think from the available data that the rate of absorption of citrated blood from the peritoneal cavity of the child is at first very rapid, then gradually slows down until the process is completed. Further research along this line is needed. The ultimate question is not one of absorption, but rate of absorption.

d. Comparative Reactions and Results Following Intraperitoneal and Intravenous Transfusions.

Careful observations of temperature reactions show more or less characteristic curves. It has been noted that, in our cases at least, both intraperitoneal and intravenous transfusions are followed, in most instances, by some degree of reaction. Most careful attention to technical details has been unable, in our hands, to obviate this reaction.

In Figures 1 and 2 there have been gathered together a series of typical reactions following blood transfusions. It can be seen at once that we are dealing with two types of curves. The sudden sharp rise with the sharp fall seem to be characteristic of the intravenous transfusion.

The slower rise, plateau, and gradual drop are apparently as characteristic of the intraperitoneal transfusion. It may be noted that fairly severe reactions may occur from the use of either route. However, the intravenous injection of blood seems to give the more severe temperature rise. It needs to be emphasized, though, that the reactions were, in all instances, only transitory, and had apparently no deleterious effect upon the patient.

As might be expected, the pulse rate as a rule goes hand in hand with the rise in temperature. It apparently returns to normal sooner than the latter. At no time were the pulse rates alarming and no irregularity of heart-beat discernible.

General symptoms, such as malaise, headache, pain, etc., were noted in a minor degree in a few cases. They applied equally well to both forms of

transfusion. These symptoms also were transitory, and cannot justly act as contraindications.

In Tables V and VI, we have summarized, for purposes of comparison, the results obtained after intraperitoneal and intravenous transfusions.

It can be seen that six out of eight cases receiving intraperitoneal transfusions were apparently benefited. In eleven other cases, receiving intravenous transfusions (Case 6046 died too soon for comparison), seven appeared to be improved. It is realized that direct comparisons, due to different etiological and clinical factors, cannot be made. Tentative conclusions are, however, justified.

The occasional limitations of even direct intravenous transfusions are shown. Any explanation, due to our present lack of knowledge concerning blood physiology⁸ is necessarily uncertain. Blood destruction may apparently take place very rapidly without showing any evidence obtainable by routine laboratory procedures. Hoover and Blankenhorn⁹ have demonstrated that bilirubin may be present in marked concentration in the plasma and yet not appear in the urine.

SUMMARY

We have discussed the general theoretical and practical considerations concerning the intraperitoneal transfusion of citrated blood. Based upon a considerable amount of laboratory and clinical data obtained from all available sources, we have pointed out the practicability of this method of giving blood during infancy and childhood. The necessity for such a method of approach, its simplicity of technique, its apparent harmlessness, and the beneficial results have all been discussed. We have tried to emphasize both in the present paper, and in previous communications that this method is proposed, not as a substitute for other methods already in use, but as an addition, of possible merit, to our pediatric armamentarium.

Laboratory experiments have preceded our clinical trials. Our clinical attempts have, we believe, met with a fair measure of success. Clinical results are especially striking in cases of anemia, that is, in cases requiring blood transfusions, not primarily as stimulative agents, but as restorers of blood loss.

The limitations of the intraperitoneal route, its possible dangers, and its ultimate value remain to be seen. Only carefully conducted laboratory and

clinical investigations will tell us ultimately what we may expect from the abdominal cavity as a source of communication with the rest of the body.

The importance of the rate of absorption has been emphasized. Upon this may depend the future use of various other medications, for example, antitoxin.

CONCLUSIONS

1. The intraperitoneal transfusion of citrated blood has apparently given good results in clinical cases of anemia.
2. Its value in severe nutritional disturbances (athrepsia) is questionable.
3. Reactions following intraperitoneal transfusions are comparable to those following intravenous transfusions, but are apparently not as severe.
4. In over 50 clinical applications we have seen no harmful effect following the use of this procedure.
5. Carefully controlled clinical studies are essential to determine its possible future status.

It is again a pleasure to acknowledge Dr. E. J. Huenekens' kind permission to utilize and report the cases reviewed.

THE TREATMENT OF NON-TUBERCULOUS PULMONARY SUPPURATION*

CARL A. HEDBLUM, M.D.

Section on Thoracic Surgery, Mayo Clinic

Rochester, Minnesota

Non-tuberculous pulmonary suppuration includes abscess, bronchiectasis, and suppurative pneumonitis. Pulmonary abscess may be acute, chronic, simple, multilocular, or multiple. Bronchiectasis may be localized or diffuse. Suppurative pneumonitis may involve a localized portion of a lung or a whole lobe. Bronchiectasis, as observed clinically, is usually chronic and of long standing. Suppurative pneumonitis is essentially acute. In chronic conditions abscess and bronchiectasis often co-exist, and either may be secondary to the other. The treatment of pulmonary suppuration, to be rational, must be based on the nature, localization, and clinical course of the disease in the given case.

1. In cases of pulmonary abscess, expectant treatment, bronchoscopic lavage, pneumothorax collapse, drainage, and partial or complete lobectomy have their advocates. In many acute cases there is secondary pleuritis of such an extent that localization, either by physical findings or x-ray, is impossible. Expectant treatment, in my opinion, is indicated in the early stages of the lesion, but before liquefaction has taken place drainage would probably be of no immediate benefit. In a considerable proportion of cases spontaneous cure results. Most cases, however, when observed at the Mayo Clinic had lasted long enough for a definite abscess to form. I believe that expectant treatment in such cases is indicated, only if patients show definite evidence of improvement, or at least if they hold their ground during a few weeks of observation. To continue expectant treatment indefinitely, unless there is such improvement, will allow the condition to become chronic, the patient will come to operation in relatively poor condition, and the results following operation will be much less satisfactory, because of the changes characteristic of a chronic process. Bronchoscopic lavage may be of some benefit in cases in which the abscess is located centrally, but such abscesses are likely to heal spontaneously. Pneumothorax collapse is probably of value in cases in which

the abscess is located centrally because it promotes collapse of the abscess walls and this facilitates healing. In peripheral abscesses, on the other hand, the nearest exit for the pus is through the chest wall, and not through a bronchus, with perhaps a relatively narrow sinus opening which allows imperfect drainage. If the abscess is in the periphery, adhesions may be present which prevent collapse of the portion of the lung involved, or, if collapse is achieved, there is danger of rupture into the pleural cavity and of secondary empyema. Peripheral abscesses should be drained by a two-stage operation because of the protection afforded against infection of the pleural cavity, unless it can be shown definitely at the first operation that the pleura is adherent over the area involved. This point can usually be determined by inspection; if there are extensive adhesions, a marked thickening of the pleura underneath the endosteum of the excised rib or underneath the intercostal muscles will be found. In any case in which there is doubt as to the presence of extensive adhesions a two-stage operation is the safest course. In some cases, however, drainage is so urgently indicated that it may be safer to suture the pleura and to establish immediate drainage.

I have usually found it possible to localize the abscess definitely by means of the aspirating needle. With the needle in place, a tract is then burned to the abscess, affecting a wide open drainage of the abscess cavity. In a few cases in which it was impossible to localize the abscess by this means, a tract was burned to the area suspected and the drainage tract packed. In such cases the abscess is likely to break into the drainage tract later, or the tract may be further cauterized at later sittings. If the abscess is fairly large and there is severe coughing and much sputum, it is a distinct advantage to leave the ribs in place after separating the periosteum. The lung can then be sutured to the parietal pleura underneath the ribs; the ribs act as a splint, preventing pain and difficulty in raising sputum during the interval before the second stage of the operation, which is usually performed about a week later, when the abscess is localized with the aspirating needle and the ribs are resected. In cases of chronic abscess of long standing, in which the x-ray and physical findings show definite localization, cautery lobectomy according to the method of Graham, offers the best chance of cure. In my experience, however, hemorrhage has been a fatal complication in two

*Read before the meeting of the Southern Minnesota Medical Association at Mankato, Minnesota, May 19, 1924.

cases following cautery. In many chronic cases drainage is ineffective because of extensive sclerosis of the portion of the lung involved. A combination of drainage and cautery, particularly in cases of multiple abscesses, seems a rational procedure. Very large cavities ultimately heal, provided all the secondary pockets are widely drained.

2. Bronchiectasis is usually diffuse but may be localized. In the latter type, in which the *x*-ray shows a definite, sharply circumscribed shadow at the base, drainage has, in my experience, produced very marked improvement so long as the drainage opening has been kept patent. In the diffuse type of bronchiectasis, however, drainage is obviously contra-indicated. This condition has been generally considered practically incurable except by lobectomy; this operation has yielded a prohibitive mortality except possibly in a small group of selected cases in which the mortality has been about 50 per cent and the proportion of complete cures relatively low.

In cases of diffuse unilateral bronchiectasis, I have in the last few years performed a graded, extrapleural thoracoplasty. This operation, when sufficiently extensive to produce massive collapse of the involved portion of the lung, has resulted in improvement in all cases, and approximates a symptomatic cure in a considerable proportion. The operation has been performed typically in five stages: resection in two stages of the ribs posteriorly, including usually the third to the eleventh, resection of the remaining lower lateral segments, resection of the upper anterior segments, and resection of the remaining median segments of the upper ribs. Combined local and gas and oxygen, or ethylene anesthesia is used. After the resection of the posterior segments the nerve trunks are isolated and injected, under direct vision, with 95 per cent alcohol. The convalescence in these cases is relatively painless, and thus the patients do not object to a several stage operation. Coughing is also relatively painless, which is important in the prevention of retention of sputum, as the patient voluntarily inhibits the coughing reflex if coughing is painful. The third advantage in the injection of the nerve trunks is that the operative field for the resection of the anterior and lateral segments of the ribs is relatively free from pain. The anesthetic effect of the injection lasts for several months. Drainage is instituted for from twenty-four to forty-eight hours following each operation. Practically without exception, healing occurs

by primary intention, and the patient is up and about usually within twenty-four or forty-eight hours. The operations are performed at intervals of about one week. Such treatment is obviously indicated only in cases of unilateral bronchiectasis. It may be difficult to determine whether the condition is unilateral or bilateral. It was unilateral in 28 per cent of 400 cases studied at the Mayo Clinic. There was a question as to whether it was unilateral or bilateral in 35 per cent. In this second group it may be impossible, by physical findings or by the *x*-ray or bronchoscopic examinations, to determine the extent of the involvement. A pneumothorax collapse of the side chiefly involved has been used as a therapeutic test. If, following complete collapse of the lung, the symptoms have largely disappeared, extrapleural collapse is indicated. If, on the other hand, the symptoms continue in large measure, the condition is regarded as probably bilateral, and operation is not advised.

3. In certain cases of pulmonary suppuration the patient's chief symptoms are a chronic cough and large amounts of purulent sputum. The physical findings and the *x*-ray show typical signs of a unilateral involvement, but owing to thickened pleura and shadows produced by pulmonary lesions it may be impossible to determine whether the condition is abscess or bronchiectasis, or a combination of the two. Drainage obviously is not to be considered. A question of lobectomy would have to include the possibility of resecting a whole lung. Extrapleural collapse is a relative indication. If there is a history of frequent exacerbation of fever, leukocytosis, and a poor general condition, it is probable that the primary condition was multiple abscess. Extrapleural collapse is ineffective because of the failure to produce better drainage, and in such cases the mortality will be considerable. If, however, the clinical course is essentially that of bronchiectasis alone, very marked improvement may be expected following extrapleural collapse.

Suppurative pneumonitis is a condition which usually occurs as a complication of multiple abscesses or of abscess secondary to bronchiectasis, and often is fatal. If the process is localized to one lobe, and the patient's general condition is satisfactory, a lobectomy seems the operation of choice.

Footnote: A large number of slides, illustrative of the various types of pulmonary suppuration and of operative technic, were shown.

CONCLUSIONS BASED ON THE STUDY OF 433
HAND INJURIES*

HAROLD E. HULLSIEK, M.D.
Miller Hospital Clinic
St. Paul

An attempt has been made in this paper to enumerate the methods used and conclusions arrived at through the investigation and study incident to the treatment of 433 hand injuries.

The reason, I believe, for lack of better functional results in a large percentage of injuries of the hands is to be found, not so much in the lack of knowledge of anatomy and pathology of these conditions, as it is in the indifference and lack of respect for the various tissues and their occasionally complicated and delicate mechanisms, together with a profound disregard for the formation of scar tissue and the resulting deformities. A tendon, with its extremely delicate gliding mechanism, cannot be grasped in a forceps as one grasps the fascia in an abdominal wound, without causing tissue death and hemorrhage, either condition being sufficient to put to naught an otherwise skillful repair. A finger that is incised longitudinally on its palmar aspect will not fold at its horizontal flexion crease nor will its tendon gliding mechanism function perfectly if the tendon slings are severed. An infection which is seen once in three or four days can advance until it is quite out of control, whereas very little progress in the wrong direction is made in twenty-four hours, and if the case is seen daily this can be arrested. Such omissions as the above are usually made not because of ignorance, but rather from the fact that the case is merely that of an infected finger or hand and therefore does not merit much consideration. In many fingers or hands partial or total permanent disability can be prevented simply by careful attention daily, and mere observance of ordinary surgical principles without any knowledge or technique, especial or peculiar to the hand itself.

Our series of cases were divided as follows:

Number of cases.....	433
Lacerations	171
Cases coming to us as infections...	99
Contusions	96
Fractures	54

Phalanges	36
Metcarpals	17
Carpals	1
Foreign bodies	36
Burns	12
Dislocations	4
Palmar space infections.....	5
Average period of disability for	
lacerations	5.3 days
Infections in primary wounds.....	4.8%

The lacerations were treated on the assumption that it is practically impossible to sterilize a traumatic wound and therefore (and this thought being of major importance) that the wound be not sutured or, in case sutures are used, a few widely separated ones loosely tied.

According to the accepted teaching if a wound is seen immediately or within a certain number of hours after its occurrence, it may be rendered aseptic as possible and closed tightly. There are at least two factors that may defeat our purpose in such treatment. The first is that of swelling due to the trauma associated with the injury. This, following the tight suturing, causes the suture to be put under still more tension, tending toward the cutting through of the sutures and increasing the likelihood of infection. Secondly, the ever present risk of infection in spite of attempts at cleansing. In the tightly sutured wound there is no chance for the escape of small amounts of serum or infectious material until these have increased in such amount as to be recognized and by that time caused serious damage.

A great many methods and solutions have been used in an attempt to render the surfaces of the wounds sterile: scrubbing with green soap and water, ether, iodine, saline, primary Dakinization and any one of these methods together with débridement. In extensive and deeply lacerated wounds a thorough débridement should be done, care being taken to remove all tissue irreparably destroyed, while being equally careful not to sacrifice any parts which aid in procuring a better cosmetic or functional result. Control of hemorrhage is not as important as it is in other regions due to the relative firmness of the part and the ability of moderate pressure to control bleeding. In primary tendon repair, however, the control of bleeding is very important as a small collection of blood in the tendon sheath may cause trouble-

*Read at the meeting of the staff of the Charles T. Miller Hospital, April 1, 1924.

some adhesions. In the repair of a tendon a thorough débridement is also necessary as any bruised or badly lacerated tendon is almost certain to slough. In wounds which are extensive, either lacerations or crushing injuries, or a combination of the two, the question of injury to tendons should be definitely settled insofar as it is possible before the patient is anesthetized, and then a careful investigation and the necessary repair done. It is very distressing to casually suture an apparently superficial wound and afterward find that an injured tendon has been overlooked.

In extensive wounds we follow the practice of cleaning the area about the wound with benzine, followed by alcohol or iodine. The gross dirt is cleaned out of the wound and all tissue which is hopelessly destroyed is removed. Not a great deal of attention is paid to the sterilizing of the wound itself; however, it seems to be of some value to wash out the wound with ether. The question of tetanus and the administration of antitoxin depend upon the conditions surrounding the patient's vocation. As most of our men were factory or shop workers tetanus antitoxin was used very rarely and we have no tetanus in our series.

Any of the stronger antiseptics which are caustics and therefore cause cell death, certainly diminish the regenerative power of the tissue and thus delay union. We have occasionally used blue ointment as a primary wound dressing with good results as a preventive of infection but this has the disadvantage of leaving a moist, soggy wound the edges of which do not adhere by primary union. A dry wound is usually a clean wound, hence the importance of daily attention. Twenty-four hours after dressing a lacerated wound which has been débrided, the dressings are very carefully removed, the wound inspected and if any minute collections of secretion are seen they are gently removed with dry cloths; a dry dressing is then re-applied. It has not been sutured tightly and a collection of infectious material does not have to increase to any large amount before forcing itself to the surface. If any reddening or pain is noted the edges of the wound are spread slightly. If on the third or fourth day the signs of infection are certain the wound is treated in an entirely different manner and as an infection. In fractures of the phalanges or metacarpals complicated with wounds on the flexor surface, the daily attention is especially important as the position of the hand over the roller

allows for moisture to collect on the palm. If not changed for thirty-six or forty-eight hours such a wound will almost certainly become infected with the possibility of the infection extending down to the bone. It is almost impossible to treat ideally a fracture and an infection in the same finger or metacarpal as the principles applied in the treatment of one condition are contraindicated in the other. The hand should be cleaned up and powdered daily and there is no danger of disturbing the fragments if the dressing is done carefully.

The idea of trying to save every available bit of finger in partial or nearly complete amputations in the distal half of the finger has been consistently carried out. Very often a finger tip which appears hopelessly severed from its blood supply may be saved by carefully placing it in position and holding it in place with adhesive or a suture to two. Where part of the distal phalanx has been lost and it is important either from the nature of the patient's vocation, or for cosmetic reasons, to increase the finger to as near normal length as possible, the celluloid cuff method of Davis may be tried. A celluloid cuff encircling the finger and extending one inch beyond the end is used as a mould for the granulations, which are allowed and encouraged, to build up the end of the finger. In our series this was tried on two fingers with the addition of about one-fourth of an inch in one case and enough in the other to prevent the necessity of shortening the bone to procure a painless stump.

In lacerations or contusions involving the nail where the nail is raised from its bed, usually at the base, the nail is left in place, but a small piece excised to allow for the escape of blood. In clipping out a piece of nail, care should be exercised not to cut into or traumatize the matrix, as such treatment will result in a deformed nail.

In the repair of tendons the most scrupulous care is to be used in an attempt at as perfect asepsis as possible. Only the gentlest handling of these very delicate tissues with the careful avoidance of even the slightest trauma. As has been mentioned above, it is a waste of time to suture together crushed or lacerated tendons, as owing to the comparatively poor blood supply the tendon is sure to slough. In primary tendon repairs the necessity for supplying a gliding mechanism is not usually present but occasionally a tendon is destroyed over such a distance as to leave a defect which can only be bridged by a tendon graft including the

sheath or paratenon. Depending upon the length of the defect a graft may be taken from the sublimus tendon of the same or another finger, the palmaris longus or various other locations. The ends of the tendon should be approximated as accurately as possible without ragged edges and the sutures applied very carefully. Considering the fact that the suture takes up the pull on working the tendon for several weeks, it is readily seen that a method must be used of firm and lasting application of the suture. The ordinary suture passed through the ends of the tendon and tied will pull out quite promptly and cannot be used. Several methods of suture have been devised, any of which is quite satisfactory.

A tendon is surrounded by a sheath or epitenon only where it changes its direction. In its straight course it is surrounded by loose, flexible long-fibered, fatty tissue called paratenon. This loose connective tissue shows a marked difference, histologically, from ordinary fatty connective tissue. This tissue is adherent to and slides back and forth with the movements of the tendon. In secondary tendon repair following an infection, a gliding mechanism must be furnished if the sheath is destroyed over any great distance if one expects any degree of motion. This means transplanting a tendon, plus its sheath or paratenon. If the tendon is planted directly without paratenon or sheath it gradually becomes adherent to the short-fibered, non-elastic connective tissue and finally is held immobile. Grafts may be obtained from the sublimus, palmaris longus, long extensors of the toes or other regions; paratenon fat may be obtained over the triceps tendon and planted in the sleeve about the tendon. If the injury necessitates suturing the tendon in the middle of the finger enough tendon should be removed to allow one end of the graft to be sutured to the distal phalanx, the other end sutured to the proximal fragment in the palm where limiting adhesions are of less consequence, thus having no suture line in the course of the tendon through the finger. It is not practical to attempt to replace both deep and superficial flexors in the fingers, the profundus only being used in the repair. To do a successful tendon repair and have any degree of function the joints must be quite freely movable as a repaired tendon obviously is not strong enough to loosen up stiffened joints. The limiting adhesions in the joint should be broken up by massage and baking and

put into a condition of maximum flexibility before attempting the repair. If the adhesions do not loosen up or if a chronic arthritis is present a repair is useless. The bed in which the tendon is to be received should be loose and succulent tissue with a good blood supply, not the hard, shiny, reddened, fibrous finger through which the storm of an infection has passed. If the finger is the seat of scars and contractures it may be necessary to make a whole thickness graft in order to prepare a proper tunnel for the new tendon. If this is necessary it may be advisable to amputate the finger rather than go through a prolonged series of operations which may easily result in failure. After the repair, motion should be started early, probably the fourth or fifth day, very carefully of course, but motion none the less, to prevent the organization of microscopic clots and resultant binding adhesions.

Fractures.—Because of the compensation and litigation aspect of our cases we are very anxious to have recorded every fracture, no matter how small and apparently unimportant. For this reason radiographs were made in all cases where there was the slightest possibility of a fracture being present. In spite of including in our series a great number of cases in which the chance for a break was comparatively slight the number positive for fracture was over 50 per cent of the total radiographed. I think this illustrates the fact that fractures of the bones in the hand occur a great deal oftener than are suspected or discovered. This may seem relatively unimportant but in addition to the fact that at least some of the fractures of phalanges or metacarpals unite improperly and with poor or painful function, if not discovered and treated, there is the additional knowledge that in industrial cases an unrecognized fracture, even though it be a trivial injury, can be made to assume gigantic and fearful proportions before a jury.

The fractures of the phalanges and metacarpals are treated in a like manner, simply by putting the hand up in flexion around a roller bandage about 1.5 inches thick and extending across the hand. In cases with much displacement we use nitrous oxide and flex the hand and fingers tightly over the roller bandage. This effectively approximates the fragments and in case of the metacarpals prevents inward or palmar knuckling with a painful callus in the palm. In the case of fractures of the

distal phalanges no splints are used at all unless the patient desires to continue working, when the finger is splinted in extension.

We had in our series thirty-six fractured phalanges and seventeen metacarpals with good results in all but four fractured phalanges in which the fracture extended into the joint, and one metacarpal which became badly infected and in which union was delayed for some time.

Infections.—The average period from the time of receiving the wound or abrasion causing the infection until first treated by us was five and three-tenths days. The number of infections was ninety-nine. The number of infections occurring in wounds treated by us as primary wounds was 4.8 per cent. The ninety-nine cases include only those which were diagnosed as infections at the time of the first visit. In these are included simple infections of the skin and subepithelium tissues, paronychia, infections of the sub-aponeurotic and subcutaneous spaces, tendon sheath infections, palmar space infections and lymphangitis when limited to the hand and forearm. In the entire series only three varieties of antiseptics were used, boric acid, saline and Dakin solution. I am quite firm in the opinion that there are three things of paramount importance in the treatment of hand infections and these are, drainage, heat and moisture. I believe it makes very little difference what the moisture consists of, boric acid, alcohol, bichloride, potassium permanganate, Ringer's solution, glucose, sterile water or any one of the various solutions which have been used, so long as the strength or character of the solution does not irritate the tissue. Salt solution was used in cases treated at home, as common salt is to be found in every home. This obviates the necessity of explaining to the men about boric acid. The cases treated with salt solution apparently did as well as those treated with boric acid. In an infection which is not serious enough to warrant hospitalization the man is advised to go home and put the hand in a vessel of hot salt solution in the proportion of 1 teaspoonful to a quart of water, leaving it immersed 15 minutes every hour. Between the saline baths he is instructed to wrap several wet towels about the hand and forearm and put the hand on a hot water bag.

Paronychia are treated in the mild and early cases merely by raising the epithelium at the edge of the nail, draining the small collection of pus

and packing in a small bit of gauze, followed by wet dressings. In the more extensive cases an incision is made through the skin parallel to the edge of the nail and extending well below the sulcus of the nail, the triangular flap thus made is raised, the portion of the nail which has been elevated by the pus is removed, care again being taken not to injure the matrix or the epithelial margin at the base of the nail and thus causing subsequent deformity of the nail. Wet dressings are then used and the inflammation and pain then usually subside quite promptly.

There are, according to Kanavel, six fascial spaces in the hand, viz.: the middle palmar, thenar, hypothenar, dorsal aponeurotic, dorsal subcutaneous and lumbrical. Three of these spaces are very important and the other three are relatively unimportant. Each space receives its infection along certain definite routes and each in turn passes the infection along through equally fixed channels.

Infections of the subcutaneous and sub-aponeurotic spaces are to be drained as promptly as the exact location of the pus can be determined. This may necessitate seeing the patient two or three times before incision but also prevents the possibility of making several incisions without finding pus. The localization of these abscesses can be aided by going over the involved area from the periphery to the center with a point or pencil or applicator until the tenderest area is found. In the majority of cases this will quite accurately locate the collection of pus. As to the incision it should be made with the resultant scar in mind and the degree of limitation of function which may result. We have ceased entirely making longitudinal incisions on the palmar surfaces of the fingers, as these result in longitudinal scars which are forced to bend in flexion of the fingers and which are more or less disabling. A great many flexor surface infections of the fingers have been opened by transverse incisions extending completely across the finger. These heal up rapidly and with a minimum of disability and although apparently contrary to the tenets of anatomy seem of practical value. A Mayo scissors is probably the ideal instrument for opening pockets in the hand, especially if there is a sinus in which to insert one blade of the scissors. Even where the skin is unbroken a small opening may be made through the skin and then the scissors used. By cutting the skin carefully with the scissors, using the closed points of

the scissors as a finder, there is less risk of harming important structures than when a knife is used.

I would like to emphasize again the advisability of delaying incision in fascial space infections until one is certain of the location of the abscess. I believe nothing is gained in premature incision made in the hope that benefit will be derived from relief of tension, even if pus is not found. I think no harm was ever done by waiting until a diagnosis can be made. This is in contra-distinction to the incision in synovial sheath infections, which should be made at the earliest possible moment, and in a lymphangitis, in which it should be delayed as long as possible.

As to the anesthetic used I do not believe there is any question. An infection that is of any extent or in an important place that is opened under a local anesthetic is accomplished more by luck than otherwise if done correctly. Nitrous oxide was used in fully 95 per cent of our cases. This or ether gives the operator sufficient time, a quiet field and is not painful to the patient.

Wide incision of the space involved followed by hot boric dressings without the use of drains has been our rule. Rubber tube drains are to be discarded because of the risk of pressure necrosis and a gauze drain soon becomes filled with coagulated secretions and blood, forming a plug which obstructs drainage rather than promotes it. If it is thought necessary to insert some sort of drain to keep the edges of the wound from falling together, thickly vaselined gauze acts very well. The dressing should be changed daily or oftener if the discharge is profuse. Moist dressings are very valuable but should not be used after they have outlived their usefulness as they promote excessive granulations and tend to macerate the tissues, keeping them boggy and soft. After the acute process has been controlled, a dry dressing is all that is necessary if adequate incisions have been made.

Synovial sheath infections are surgically important because of the destruction which occurs, the rapidity with which the process advances and the possibility of rapid spread of the infection if the condition is untreated. A tendon sheath may become infected directly through a crushing injury or laceration or from a slight abrasion or even a prick of a needle. The finger in such case is found to be edematous, both on the flexor surface and the dorsum, the patient complains of tenderness on pressure at all points but it will be found that

firm pressure applied over the tendon itself is quite out of proportion to pressure over the other areas. This extreme tenderness will be found to follow the course of the sheath. On passive extension of the finger the pain is very marked and usually most severe at the proximal phalanx, the finger is held in flexion and this differs from the flexion of a fascial space infection in that motion is much more painful. The three cardinal symptoms then of tendon sheath involvement, are: first, excessive tenderness along the course of the tendon; second, excruciating pain on extension; third, position of flexion. The diagnosis is often fairly easy and can usually be made without difficulty.

Incision should be made down to the distended sheath and then the sheath incised, as far as the infection has extended. The incision may be made at the sides of the fingers and not on the flexor surfaces, one side or both sides of the finger may be incised, and the incision may be continuous, but if possible may be interrupted opposite the middle of the shafts of the phalanges, thus avoiding slings which hold the tendon taut and also preventing prolapse of the tendon. The size of the opening is of prime importance and must be large enough to drain the infected area freely. It is better to have it too large than too small. If the entire finger is involved the proximal and middle phalanges should be opened, incision in the distal phalanx being usually unnecessary. The proximal end of the incision is carried down into the palm according to the amount of palmar involvement. If the lumbrical space is involved the lateral incision is carried down the lumbrical muscle. If this involvement has not occurred, incision is made in the midline over the palmar end of the sheath and extends from the flexion crease at the base of the proximal phalanx about three-fourths of an inch into the palm.

Infections involving the fingers traverse different routes and involve different areas depending upon the finger primarily involved and whether the infection is lymphatic, fascial or through the synovial sheath. Fascial space infection in the index finger may spread dorsally onto the back of the hand, into the webbed space between the first and second fingers or along the lumbrical muscle and thus into the middle palmar space. If the metacarpo-phalangeal joint of the finger is also involved with destruction the flexor space may be involved.

In the thumb fascial infection does not tend toward the thenar space but rather away from it. In the second and third fingers the route lies also toward the dorsum of the hand and toward the mid-palmar space. In the little finger it is uncommon but the infection may burrow into the middle palmar space.

As to the spread of synovial sheath infections: this also varies in the different fingers. In the index finger the pus, having ruptured from the proximal end of the sheath, lies in the loose connective tissue about the lumbrical muscle, along which it extends and finally ruptures through a thin sheet of fascia into the thenar space.

In the invasion of the flexor longus pollicis of the thumb the sheath ruptures, allowing the pus to come to the surface, or it extends down the radial bursa. From here it may find its way into the ulnar bursa through a direct communication which often exists, or by rupture. If the sheath ruptures in its distal part it may thus become a fascial space infection and pass to the thenar space.

In the second finger the extension is to the mid-palmar space and in the third finger the same. In the fourth finger in cases where the sheath connects with the ulnar bursa, this becomes involved. In this finger rupture at the proximal end of the sheath may take place, the pus then reaching either the bursa or the mid-palmar space.

Extension by means of rupture through the ends of the radial and ulnar bursa is the common cause of deep abscesses in the forearm. These may be drained by lateral incisions at the level of the flexor surfaces of the radius and ulna, communicating with one another under the tendon of the flexor profundis.

The importance and value of proper treatment of fascial space and tendon sheath infections, and thus preventing extension to the palmar spaces, is shown by the fact that we had only five cases in

ninety-nine infections in which the palmar spaces were drained. In three cases it was found necessary to amputate a finger either because of hopeless necrosis of tendons, combined with an extensive infection, or of involvement of the bone itself.

In our cases in which the mid-palmar space was drained the incision was made after the technique outlined by Kanavel. An incision is made on the flexor surface of the palm along the lumbrical muscle of the second, third and fourth finger, depending upon where the most marked involvement lies, preferably between the second and third finger. The incision is carried down to the tendons, the forceps is inserted between the tendons and the points spread apart in the space beneath and a small strip of vaseline gauze inserted. To open and drain the thenar space an incision is made opposite the middle of the index metacarpal on a level with its flexor surface.

The after-treatment of fascial space infections consists of hot, moist dressings, together with active and passive motion very early. Following the clearing up of the infection, massage, moist and dry heat and diathermy are very valuable. We have found that these procedures under our personal guidance, or of one trained in physio-therapy, are infinitely more beneficial than when left to the discretion of the patient, who does not realize that the valuable time he is spending waiting for the joints to become less painful, is also being spent in firmly organizing the exudate which later will permanently disable him.

In our burn cases, none of which were very extensive, we used 2 per cent salicaine ointment, which we believe has some anesthetic effect, thus rendering the injury less painful. The saline is used later to keep the tissues soft, remove the crusts and exudate and allow motion with less pain and thus prevent contraction. In two of the burns, grafts were used to hasten epithelialization.

SOME NEW PROBLEMS IN OBSTETRICS*

W. H. CONDIT, M.D.

Minneapolis

The scientific, economic, social and mechanical problems of the day are taxing the skill of the best minds to the extreme. Second to none is the problem of the automobile, which is influencing to no small degree all classes of society. The automobile as a means of transportation is with us to stay and is causing a marked increase in casualties to human life, antepartum as well as to those already on the way to the age of discretion and individual responsibility.

Accidents to intrauterine life and how to prevent them is a problem which daily confronts our profession. We are all asked the question by the antepartum and postpartum mother, "How soon can I ride in a motor car?" and almost as often, "When can I drive one?"

What are the factors incident to the accidents that present for consideration? I have classified them as (a) Mechanical, (b) Physical, and (c) Emotional.

Mechanical Factors.—The mechanical irritations are varied and in many ways cause abortions, miscarriages and premature labor, most often from direct violence to the mother. We have recently noted many more anomalies in the fetal cord, such as complex knots, coils about the neck and fetal extremities and, of much more moment, turns under the axilla over the shoulder and then around the neck, which predispose to strangulation of the cord against the bony parts in the last few moments of the second stage, thus stimulating the fetus to inspire in the lower canal or even causing death from direct strangulation of the cord. These observations have necessitated unusual care and caution in watching the fetal heart during the last of the second stage and in three cases I feel sure this concern saved the life of the fetus in each instance. The pulse becoming slow, irregular and arrhythmical, forceps were immediately applied and delivery hastened, resulting in a living child, which other-

wise would have been lost. I urge all who have not the aid of an assistant to watch the fetal heart-beat, to wear the head stethoscope and use it after every pain during the latter part of the second stage of labor. The three cases above mentioned were all cord complications.

This same mechanical stimulation can cause more abnormal positions and presentations, which always contribute additional hazards to a successful delivery. Again, we may have this factor causing premature rupture of the fetal membranes or premature separation of the placenta, which may be very slight, causing only a mild hemorrhage, contributing to placental infarcts and their complications, or producing any degree of hemorrhage to complete separation.

It has been my experience with these patients who drive motor cars and insist upon doing so up to or near maturity, to have premature or false labor, requiring absolute rest in bed for seven to ten days, in order that the uterine muscle may recover so that the contractions would have some muscular strength and efficiency. One patient in particular who had false pains for three days, with no progress, was put in bed and as long as quiet, would experience no contractions, but the slightest movement, as going to the toilet, would stimulate this irritable, tired muscle to contractions. Rest in bed for five days, use of small doses of morphine and chloral, brought about a recovery of the muscle strength of the uterus. Another test of labor resulted in irregular pains during the second stage, one intermission of one hour without a single contraction, then a precipitate delivery with one good pain. This patient was of special interest, as this was her fourth delivery, the second and third being precipitate following a very short labor.

Physical Factors.—The physical disturbances may not contribute so materially to complications of pregnancy as the mechanical, but still have no small share. Long journeys by motor contribute to general physical tiring, muscular pains, especially backache, particularly riding in the rear seat, which is set on the incline, causing more intra-abdominal pressure on and irritation to the uterus. Inability to empty the bladder and bowel when the call of nature demands is no slight irritation to the physical economy, especially if there be an unusual tendency to constipation or bladder irri-

*Read before the Southern Minnesota Medical Association, Mankato, May, 1924.

tation. Any interference with normal elimination and metabolism in the mother contributes to nutritional impairment in the embryo. Long distance motoring contributes to digestive disturbances in irregularity of meals and inability to secure the proper foods.

Emotional Factors.—Last but not least, is the emotional feature accompanying motoring—for example, riding at night in a storm or on uncertain roads, with apprehension of danger or accidents. I have had two patients abort at the third month of gestation from anxiety and fear attending a trip in a rain storm on slippery roads, without an accident or any mechanical disturbance. Again, sudden emotion on just missing running down an individual or the killing of an animal or fowl along the road is detrimental. Many pregnant women are so sentimental about their condition that they will not inform a driver of their delicate condition in order that more caution in driving be taken.

How are we to educate our patients on these points and impress upon them the gravity of the hazards attending motoring? I have anticipated presenting my patients with printed instructions. I always inquire whether they are accustomed to ride frequently in motor vehicles or whether they drive one. I instruct my patients to absolutely forego riding in a motor vehicle, especially the crowded, rough riding bus, during the first, third, seventh and last months of gestation, to avoid rough or long trips at any time and when riding, to choose the front seat, which has a right angle position and good foot support.

CONCLUSIONS

1. Without question transportation in an automobile very materially increases intrauterine complications of pregnancy and intrauterine death of the fetus.

2. We, as professional advisers and promulgators of prophylactic medicine, are in duty bound to warn our pregnant women of these hazards.

3. By intelligent instruction to our prospective mothers, we can no doubt diminish these accidents.

4. This new hazard, added to the many attendant on the pregnant state, is one that will add mortality and morbidity to the mother as well as the fetus. This subject doubly demands our attention in an effort to reduce the mortality which is still second only to that from tuberculosis.

PNEUMONIA AND ITS TREATMENT WITH PNEUMOCOCCUS ANTIGEN*

DONALD B. PRITCHARD, M.D.
Winona, Minn.

During and following the influenza epidemic of 1918 there has been a very great morbidity from pneumonia and the mortality has been very high. This is my excuse for burdening you with a paper at this time. I confess that I have hesitated to appear before a meeting of medical men to tell them of my experience with the use of pneumococcus antigen in the treatment of pneumonia because of the difficulty in evaluating the results of any form of treatment in this disease. To those who have had no experience with pneumococcus antigen in the treatment of pneumonia it may appear that I either do not know a pneumonia when I see it or that I am greatly exaggerating the results obtained. From October 6, 1918, to May 1, 1924, I cared for 124 cases of pneumonia, all but one of which was more or less thoroughly treated with pneumococcus antigen, a method developed by Dr. E. C. Rosenow.

This antigen consists of a salt solution suspension of partially autolyzed highly virulent pneumococci of the different types. The autolysis under ether at 37° is allowed to proceed until nearly all organisms have become gram negative and suspensions have lost their toxicity as determined by intravenous injection in guinea pigs, and subcutaneous injection in man. The dose for adults consists of 1 c.c. containing twenty billion partially autolyzed organisms, subcutaneously, daily until the temperature becomes normal and remains so for one or two days, or until it is apparent that it has no good effect. Rosenow has shown that the anti-bodies increase more rapidly, the local and constitutional reaction is much less marked than following injection of the ordinary pneumococcus vaccine and that, with the partially autolyzed dead organisms, animals can be protected against otherwise fatal doses of highly virulent pneumococci, if treatment is begun soon after inoculation of the test organisms.

In my review there has been a total mortality of nine, or slightly over 7 per cent, but the death rate tells only a part of the story. Of the 124 cases, forty were twelve years of age or under, eighty-

*Read before the Southern Minnesota Medical Association, Mankato, May, 1924.

four were over twelve, and six of these were over seventy-five years of age. There were fifteen lobar and twenty-four broncho-pneumonias in those of twelve years of age or under, and forty-one lobar and forty-four broncho-pneumonias in those over twelve years of age. Of the lobar pneumonias twenty-nine involved the left lung, fourteen the right lung, and in two cases both lungs. In the remaining eleven patients my notes do not specifically specify the area involved. The broncho-pneumonias were more or less generalized. In some only a comparatively small area was involved while in others it was very extensively scattered over both lungs.

First I will briefly detail the cases that died.

An old nephritic case developed in the afternoon a severe hemorrhagic pneumonitis. When I saw him a short time after, he had crepitation and râles all over both lungs. The temperature was 104.6, pulse and respiration were very rapid, he was decidedly cyanotic, coughing up great quantities of blood. I gave him a dose of pneumococcus antigen but he died in twenty hours.

A man, age thirty-six, weighing considerably over three hundred pounds, 5 feet 9 inches tall, had been sick for three days following a preceding attack of influenza. His temperature was 103, pulse 146, respirations 48, he was very cyanotic, and both lungs were involved in an extensive broncho-pneumonia. I gave him a dose of antigen and in eighteen hours he died.

A girl, age seventeen, with no preceding illness, developed a lobar pneumonia involving the lower lobe of the left lung and in two days after administration of pneumococcus antigen she apparently recovered, her pulse, temperature, and respirations having become normal. Four days later she complained of severe headache, was vomiting, and died of a cerebral meningitis in four days.

Two other patients, an uncle and a niece in the same household, both ill at about the same time with influenza, were attacked with broncho-pneumonia which gradually grew worse as they became intensely cyanosed, and in spite of antigen both died without its seeming to have the slightest effect.

A man of 74 years, who had a hemiplegia of the right side due to an arteriosclerosis and recent cerebral hemorrhage, sickened with broncho-pneumonia, from which he died on the fifth day.

A woman, aged 78, had influenza followed by a

broncho-pneumonia, from which she was apparently quite convalescent in three days. Two days later she developed an acute mania, and died in ten days.

A child, aged 4, seen when she had been ill for several days with a broncho-pneumonia following measles, died on the tenth day after I saw her, showing no response to treatment.

A little girl, aged 8, had been sick with influenza seven days when I called to see another member of the family and before leaving I asked how the little girl was. They said that she was still in bed but that she was better and that they expected she would be up the next day. I went into her room to greet her; her skin was cool and of good color, pulse not over 80, respirations not hurried, and she looked as if there was nothing much the matter with her. As I turned to leave the room, I thought I had better take her temperature, which I did, and to my surprise she had a mouth temperature of 103. I examined her chest and she had an extensive broncho-pneumonia that undoubtedly had been present for some time. On that day my supply of pneumococcus antigen was exhausted but the next morning (they lived some miles in the country) I called to see her. She was then practically pulseless at the wrist, respirations were rapid, she was very dull and apathetic, and cyanosed. I did not administer antigen and she was dead within three hours.

In none of the 124 cases treated did empyema develop, which I think is significant. I have included all the pneumonias seen by me from October 6, 1918, to May 1, 1924, and except the case noted all received more or less antigen. If you will bear with me for a few minutes more I will describe a few of the rather striking results obtained.

I have already spoken of the rather startling result in the first case in which I administered it. In a girl of seven, suffering from a sudden and very acute attack of broncho-pneumonia following influenza, with a very high temperature, rapid pulse, rapid respiration, crepitations, and râles generally distributed throughout the chest, in twelve hours after a dose of antigen the temperature, pulse and respiration had practically attained normal and in twenty-four hours she was convalescent. It is no wonder that I doubted my senses, as this was my first experience with it.

Early in the epidemic one of the pupil nurses

in the hospital came down with influenza and on the morning of the third day her temperature was normal and she seemed to be on the way to convalesce. In the early afternoon they telephoned me that she was very much worse. Her temperature had reached 104.6° , pulse 120, respiration 30, and she was coughing a great deal, raising a bright red sputum, and complaining of sharp pain in the chest, but the physical findings were not very definite. She looked anxious and she was a very sick girl. I at once administered pneumococcus antigen. The next morning she was very much better and there was a definitely dull area with blowing breathing in the lower lobe of the right lung. Another dose of antigen was given. The next morning she was apparently well. I had no more antigen to give her. Two days later she began running a temperature and on the third day she seemed to be as ill as when I first saw her. On the fourth day I gave her another dose of antigen, with results similar to the effect of the first. In two days she was again convalescent. This time she had three doses on successive days and made a prompt recovery.

At about this time I had a young man with a hemorrhagic pneumotitis, who coughed up great quantities of blood. He had been a brewery worker for years and was not a good subject for pneumonia. I gave him two doses, twenty-four hours apart, and as I was again out of antigen he got none until three days later. In the meantime his temperature shot up, his cough and hemorrhages recurred, when I was again able to give him a dose for two days in succession. On the second day after that he began coughing, temperature and pulse went up, which continued for two days, when I was able to give him some more antigen, and this time I continued it for three doses, after which he remained well.

In February, 1921, I saw in consultation with Dr. Scherer, of Duluth, a five year old girl who had been sick with influenza for three or four days, and after being dismissed by the doctor at his morning visit he was called back in the afternoon and found his patient very ill with oncoming broncho-pneumonia. The family telephoned for me and at 9 a. m., the next day, about twenty hours after the onset of the pneumonia, I saw her with Dr. Scherer. She had passed a very bad night, her temperature was high, pulse and respiration rapid, and she was mildly delirious. She had a

well developed and extensive broncho-pneumonia. We administered pneumococcus antigen and at 9 p. m., some twelve hours later, we saw her again, and the record showed that in the early afternoon improvement began and proceeded rapidly, and at this visit her temperature, pulse, respiration had practically reached normal, her nervous condition had become greatly improved, and the further progress was a prompt and uneventful recovery.

This spring I saw two extensive broncho-pneumonias following measles. They promptly subsided so far as the toxemia of the pneumonia went and they were practically over it within 48 hours. One of them, a boy twelve years of age, sick three days with measles, his mouth temperature 105.2° , pulse 170 and not of good quality, respirations ranging from 55 to 60, was extremely cyanotic and the alae of his nose were dilated. He had an extensive broncho-pneumonia throughout both lungs. I gave him 1 c.c. of the antigen and when I saw him the next morning, twenty-four hours later, his color was good. The rectal temperature had dropped to 101.2° , mouth 100, pulse 124, respirations 30, but he seemed to be rather dull and apathetic. The antigen was repeated and he made an uneventful recovery.

There were two other cases of hemorrhagic pneumotitis with unusually severe onset which recovered within forty-eight hours after administration of pneumococcus antigen.

Three years ago a girl, aged four, became ill with a left lower lobe infection. She began quite acutely and twelve hours after her first dose of pneumococcus antigen her temperature, pulse, respirations had reached normal. At my visit the next morning she was as ill as at my first visit. She was given a second dose of antigen and at night the symptoms had markedly abated, but the next morning she had again become as ill as ever. I repeated the antigen and at night, while she had again seemingly recovered, I repeated the dose and for the next two days I gave the injections morning and evening and her recovery was prompt.

Time will not permit the citation of many other cases with seemingly marked beneficial effects.

I am aware that some of these cases might have aborted without pneumococcus antigen, but not with the uniformity that I have experienced. I have been in practice for thirty-seven years and can recall but one case of pneumonia that aborted

in twenty-four hours excepting those treated with the antigen.

In some cases the effect is not so striking and recovery is by gradual daily improvement, extending over six or seven days. Success depends upon early diagnosis and treatment. I would almost as soon care for diphtheria without diphtheria anti-

toxin as to be responsible for pneumonia without pneumococcus antigen, and I have had experience in both diseases with and without these remedial agents. Dr. Rosenow has done much to advance medicine, but I think this product of his brain, while of great value to the practitioner, is the least appreciated of his contributions.

A MEDICAL CENTER IN THE ORIENT

"The visitor to Peking today who has had no warning in advance is surprised to find on the site of what was once the palace of a Chinese prince, a group of beautiful buildings which make a somewhat puzzling impression. At first glance they seem to be of classic Chinese architecture. The curved roofs of glazed tiles, the elaborately decorated eaves, the formal courts, the white marble steps and balustrades, the main gate guarded by archaic lions—all seem characteristically Chinese. But on closer examination other features are noted. The buildings are of brick, two, three, or even four stories high. The windows are large and glazed. Yonder rises a tall chimney evidently belonging to a power-house. Half hidden at one side one recognizes the storage tank of a gas-plant. Here evidently is an institution of the West which has assumed some outer aspects of the East. It is the Peking Union Medical College, built, equipped, and maintained with funds supplied by the Rockefeller Foundation through the China Medical Board.

"In these laboratories, classrooms, and hospital pavilions teaching and research are being carried on in the modern scientific spirit, by well-trained men and women from many parts of the world. The 78 members of the medical school and hospital staffs who hold medical degrees represent 38 medical colleges of 11 different countries. In increasing numbers Chinese scientists and doctors are being welcomed as members of the faculty and advanced to positions of responsibility. In a premedical course students are being prepared to enter the regular undergraduate medical school. A school of nursing is a part of the plan. Graduate students, Chinese physicians, and medical missionaries on furlough from their stations are pursuing special studies or serving as voluntary assistants. From time to time brief intensive courses are organized in medicine, surgery, the clinical specialties, the fundamental laboratory sciences, and roentgenology for groups of doctors who wish to keep abreast of recent progress. Visiting professors from Amer-

ica and Europe have a share in these courses as well as in other teaching, and bring to the institution the stimulus of their ability, experience, personality, and prestige.

"The main scientific and professional aims of the College are: (1) to provide an undergraduate medical training of high standard, (2) to afford facilities to physicians for graduate work, (3) to give special preparation to prospective medical teachers and investigators, (4) to offer opportunities to staff members and advanced students for research, especially with respect to diseases of the Orient, and (5) in various ways to increase popular knowledge of the methods and meaning of modern medicine. The College is a development of an institution founded under missionary auspices. It seeks to perpetuate ideals of high character and loyal service and to work in sympathetic relations with the missionary movement and with the Chinese themselves."—*The Rockefeller Foundation*.

TEN WAYS TO KILL A MEDICAL SOCIETY

Don't go to the meetings.

If you do go, go late.

If the weather doesn't suit you, don't think of going.

If you do attend a meeting, find fault with the work of the officers and members.

Never accept office, as it is easier to criticize than to do things.

Get sore if you are not appointed on committees, but if you are do not attend committee meetings.

If asked by the chairman to give your opinion on some matter, tell him you have nothing to say. After the meeting tell everyone how things should be done.

Do nothing more than absolutely necessary, but when members use their ability to help matters along, howl that the institution is run by a clique.

Hold back your dues, or don't pay at all.

Don't bother about getting new members. "Let George do it."—*Pittsburgh Medical Journal*.

EDITORIAL

The Pasteurization of Milk

Milk is one of our most valuable and most extensively used foods. It is also a very ready medium through which certain communicable diseases may be spread if measures are not taken to safeguard it. A safe milk supply is now recognized as one of the fundamental requirements in the protection of public health.

The most economical and effective method of rendering milk safe, and the one which is universally recognized, is pasteurization. Health authorities now agree that all market milk should be pasteurized, unless it has been produced and handled under conditions similar to those required for certified milk. Pasteurization should not be counted on to make up for lax or unclean methods of production; its purpose is primarily to overcome certain dangers in raw milk which even the most highly developed systems of dairy inspection may not eliminate.

Milk is pasteurized by heating it to a temperature not lower than 145° F. for not less than thirty minutes, and then promptly cooling it to 50° F.,

or below. Pasteurization under this method does not render the milk sterile, but makes it safe insofar as the transmission of disease is concerned. A number of types of harmless but desirable bacteria which cause milk to sour are not killed by this heating process, so that pasteurized milk sours in the same manner as raw milk, although the time it remains sweet is prolonged about twenty-four hours.

The process of pasteurization as carried out at the present time by the "holding" method causes no appreciable chemical change in the milk; it tastes practically the same as raw milk and the food value is not materially affected.

Milk, unlike any other single food, contains all three vitamins and the effect that pasteurization may have on them is of importance. Fat-soluble vitamin A and water-soluble vitamin B are quite resistant to heat and it is agreed that pasteurization has little or no effect upon them. The antiscorbutic vitamin C is sensitive to heat at about 122° F. While the destruction of this vitamin depends upon the temperature, length, and condition of heating, as well as on the reaction of the material in which it exists, pasteurization of milk undoubtedly weakens the antiscorbutic property of the milk to some extent. It has been found that milk freshly drawn from the cow at certain times of the year does not always contain a sufficient quantity of vitamin C to protect against scurvy. This variation in the vitamin content of the milk is determined by the kind of food which the cow receives. Since even fresh, raw milk may not contain a sufficient quantity of vitamin C, most physicians recommend that this vitamin which is present in orange juice, tomato juice, etc., be added to the diet when cows' milk is substituted for breast milk. In view of the fact that vitamin C must be substituted in the infant's diet regardless of whether or not the milk is pasteurized, a partial destruction of this vitamin resulting from pasteurization is of little practical importance. Since adults do not depend on milk as a source of vitamin C, pasteurization cannot be said to have a detrimental effect on the food value of milk insofar as they are concerned.

In consideration of the protection against disease that proper pasteurization offers, there is no longer any question as to the value of the process from a health point of view. In cities where all of the supply is pasteurized, milk-borne diseases have been practically eliminated. The United

States Department of Agriculture makes the statement that "no epidemic of disease has ever been traced to properly pasteurized milk."

The State Meeting

For the first time in history our State Association, at its annual convention, is to be the guest of St. Cloud. Until recently it was considered that the hotel facilities of St. Cloud made it impossible to meet there. With the completion of the Breen Hotel this difficulty has been removed, although the local committee expects such a crowd that the hospitality of private homes will have to be accepted. The St. Cloud physicians and, in fact, the residents in general, are apparently going to show what royal entertainment they can extend. Each and every member is urged to do his best to attend.

The St. Cloud convention will afford a good opportunity for our wives to go on a little spree. They are to receive special entertainment and St. Cloud has some interesting activities worth seeing, for instance, the granite quarries, paper mill and State reformatory. And then there is golf.

A perusal of the scientific program which appears elsewhere in this issue should convince one that the program committee has arranged something which promises to be worth going to St. Cloud to hear. Of course, the addresses are to be published later, but reading a journal is not a good substitute for meeting your professional friends and holding those informal professional discussions which are so valuable.

The innovation of publishing the committee recommendations in advance of the meeting has been carried out this year and the reports appear in this issue. The advisability of attempting to establish a state medical library is brought up in an editorial. The suggestion has been made to the secretary of the Association that we establish a fund for the financial assistance of the needy ones in our ranks, particularly the aged and incapacitated. There is much to recommend such a step. These matters should receive the consideration of members and particularly the delegates in advance of the meeting, so think them over.

The absence of two of our prominent members is going to detract from our full enjoyment of the meeting. The illness of our president, Dr. Archibald MacLaren, will prevent his attending and presiding at our sessions. We shall all miss him

greatly and sincerely hope for his speedy recovery. It is more than to be regretted that Dr. Beebe, who has played such a prominent part in the medical life of our Association and who was responsible for the choice of St. Cloud for this year's convention, will not be there to greet us.

Dr. E. T. Sanderson, our first vice president, expects to be present at St. Cloud and will preside.

Till we meet in St. Cloud, then!

A State Medical Library

Several of the larger county medical societies have medical libraries for the use of their members. Perhaps 50 per cent of the physicians in the state, however, are without the use of a first-class library. They must depend upon the few books and periodicals they have individually been able to get together. This is a distinct disadvantage when it comes to keeping up with medical progress or preparing medical papers.

There is a medical library, state supported to be sure, at the University. Recently it has been fused with the biology and dentistry libraries to form a department of about 50,000 volumes in the University library. During the summer the medical books were transferred to the new University library building which, by the way, is a magnificent structure. The University library is admittedly for the use primarily of the faculty and secondarily of the students of the University. No provision has been made for the loan of books to outside individuals. Possibly, however, if a demand for a circulation department of the medical library were shown, this could be obtained with little effort.

Circulatory medical libraries do exist. That of the Medical Society of the County of Kings in Brooklyn and that of the College of Physicians and Surgeons in Philadelphia are notable examples. The Surgeon General's library in Washington loans medical literature extensively, but only through a reliable organization such as a county society library.

New York has maintained a state medical library at Albany for many years. Three years ago a medical branch of the Iowa State library was established with its own librarian and quarters in the Historical Society Building at Des Moines. This latter may well serve as an example of the need and practicability of such an institution. Ten years ago the State librarian in Iowa, convinced

of the need of medical books in the State library, began to accumulate a few volumes. In 1920 the General Assembly of Iowa created a medical department. A small appropriation is made each year for a librarian's salary and the purchase of books and periodicals. Assisted by contributions from various sources, the library now has some 5,000 volumes. It is reported that 10 per cent of the profession outside of Des Moines and 5 per cent of the profession in the city use the library. This percentage will doubtless increase as the library becomes better established.

Our State maintains a library of some 90,000 volumes at the State Capitol for the law profession. It is worth while for the State to furnish facilities for self betterment to the lawyers. Why does not the same apply to the medical profession? A lawyer can go to the state house and camp in the library. A physician, in most instances, could not and the service of a medical library would be largely through the loan of literature.

Iowa has a state medical library; why not Minnesota? The time is propitious to take up the matter at our state medical meeting this month and provide for a thorough investigation of the proposition.

COMMITTEE REPORTS

The following reports have been submitted by the chairmen of the respective committees and are published for the consideration of the members of the Association and particularly the delegates, in advance of the annual meeting:

COMMITTEE ON MEDICAL EDUCATION AND HOSPITALS

To the President and House of Delegates of the Minnesota State Medical Society:

Gentlemen: Your Committee on Medical Education and Hospitals has the honor of submitting the following report:
FIRST: HOSPITALS:

In its work of raising the standards of hospitals the Council on Medical Education and Hospitals of the American Medical Association has adopted the plan of publishing a list of hospitals approved by it for the training of interns.

In addition to an investigation of each hospital by a representative of the Council from the home office at Chicago, the Committee on Medical Education and Hospitals of the state in which any hospital applying for approval is located is asked to make an independent investigation and report to the Council. Your Committee was requested to make one such survey during the year, namely, of the New Asbury Hospital of Minneapolis. The survey was made and the hospital recommended for approval by the Council. Seventeen hospitals in Minnesota are now approved for the training of interns.

SECOND: MEDICAL EDUCATION:

The Committee on Medical Education and Hospitals of last year, headed by Dr. Braasch, made a very comprehensive and valuable report on both undergraduate and graduate medical education in Minnesota.

Your present Committee will therefore not go into any detail concerning the present status of medical education in the state, but will first take up the recommendations of Dr. Braasch's Committee to see whether or not the profession of the state has profited by those wise proposals. Too often recommendations of Committees which have spent valuable time and concentrated effort on their work are literally thrown into the waste basket by the hackneyed motion "I move the report of the Committee be accepted and placed on file." Therefore, your present Committee makes but one recommendation with the hope that the Committee next year will be instructed to concentrate all its efforts on education to be carried to the physician in his own locality.

The recommendation of Dr. Braasch's Committee:

"That the University of Minnesota offer several courses of instruction at different periods of the year and possibly in a more concentrated form" has been carried out by the University.

In the spring, for two weeks, courses were offered "in a more concentrated form" in Medicine and Surgery, and in the fall for another two weeks in Pediatrics and Obstetrics and Gynecology, together with a one week's course in x-ray diagnosis, laboratory clinical and pathological diagnostic methods.

Another recommendation of last year's Committee was:

"That a system of graduate medical instruction be given by competent instructors in various portions of the state enabling the general practitioner to become familiar with recent medical progress." This has been taken up by your present Committee, which begs leave to make the following report of its investigations with recommendations for putting it into effect: Certain states, notably Wisconsin and North Carolina have undertaken to take instruction to the practitioner. Time and space will not permit a detailed description of this work but the essential features of the plan are these:

Wisconsin. "The purpose of the courses offered in post-graduate medical instruction is to provide physicians, residing in a given locality, with practical demonstrations of the newer methods of diagnosing and treating disease. Clinics are held at a hospital conveniently located, illustrated lectures are given, and opportunity is offered for consultations with specialists. Arrangements may be made for a single clinic and lecture or for a series of weekly, bi-weekly, or monthly clinics and lectures. Arrangements for these clinics and lectures are made through co-operation between the local physicians under whose auspices the clinics and lectures are held and the Dean of the University Extension Division. Physicians enrolling for the course are charged a fee sufficient to cover part of the overhead expenses, the balance is paid from the small appropriation made for this work by the state legislature. The following courses, each consisting of one clinic and one lecture, are offered:

Internal medicine, radiology, pediatrics, dermatology and

syphilis, neurology and psychiatry, genito-urinary diseases, orthopedics, laboratory diagnosis; diseases of the eye, ear, nose and throat; obstetrics and gynecology.

The courses are given by teachers from the University of Wisconsin and prominent professional men of the state.

In addition to these courses obstetrical films are exhibited and the cancer propaganda is conducted in harmony with the above courses by a committee of the State Medical Society of Wisconsin, illustrated by 125 slides.

North Carolina. In this state the work is also conducted by the University Extension Division.

Mr. Chester D. Snell, Director of the Extension work in a letter to Mr. R. R. Price, Director of the same work at the University of Minnesota, says:

"I should like to make it clear that the work which we are offering is regular post-graduate medical instruction, and is not devoted to clinics alone. Each class meeting last summer lasted about three hours, of which an hour and a half, approximately, was devoted to a lecture by the instructor and the rest of the time was taken up by clinical work. Some of the meetings lasted a whole afternoon when the classes got interested in the clinical work.

"We ran two circuits of six towns each last summer, and the total attendance in each circuit was one hundred each, or an average of seventeen in each group or class. This next summer we expect to run at least six circuits, and hope to have practically all the general practitioners in this state taking the work.

"Let me say that as far as we are able to judge, this work has been a tremendous success in this state, and we believe we have found a solution of the problem of how to give busy doctors post-graduate medical instruction without great expense or loss of time to them.

"The plan is briefly this: The University Extension Division, in co-operation with the Dean of the Medical School, serve in an organizing capacity. The best available instructor in the country is secured to give the course. Between ten and twenty physicians are assembled at five or six conveniently located towns accessible to the instructor on one day each week for twelve weeks. Each meeting consists of a one-hour lecture and from one to two hours of clinical work. Each group therefore receives a total of twelve lectures and twelve clinical demonstrations. The cost to each person is guaranteed to be not more than thirty dollars. Should the total receipts exceed the cost, the excess will be refunded pro rata.

"Post-graduate medical education is a necessity because of the rapid advancement in medical science. The average general practitioner cannot afford to be absent from his practice six weeks in order to take a course in residence at a cost of \$400 or \$500. What is now known as the 'North Carolina Plan' was inaugurated in the summer of 1916.

"Two instructors were appointed. Each was assigned to a circuit of six centers, which he covered in rotation every week for four months, a class thus being held in each city once a week. The classes were composed of physicians residing in these centers and their surrounding rural communities.

"The actual organization of the classes, and the planning of the instructors' routes and other executive work was

carried out by the University Extension Division, while the more strictly medical problems, notably the selection of the instructors and the outline of the work, were in the hands of the Dean of the Medical School."

The experiment in these two and other states has been very successful. Your Committee believes that the profession of this state will welcome an opportunity to broaden its knowledge and to keep up with medical progress which some such plan will furnish at a minimum expenditure of time and at a reasonable cost.

Therefore, your Committee recommends:

1. That the Committee on Medical Education and Hospitals be instructed to confer with Mr. Richard R. Price, Director of the Extension Division, and Dean Lyon of the Medical School, as to the feasibility of the scheme. (Mr. Price and Dean Lyon have expressed to the Committee their willingness to co-operate with the State Medical Society in every possible way.)

2. If found to be practicable to adopt a plan suitable to the peculiar conditions in Minnesota and

3. Subject to the approval of the Council to put the plan into effect in co-operation with the Director of the Extension Division and the Dean of the Medical School of the University of Minnesota.

4. Finally, your Committee believes that the plan can be made self-supporting, but it realizes that in inaugurating any new scheme there may be some incidental expenses necessary, we therefore recommend that a small appropriation be made to insure success.

Respectfully submitted,

A. R. COLVIN.

E. S. JUDD.

J. C. LITZENBERG, Chairman.

COMMITTEE ON PUBLIC POLICY AND LEGISLATION

To the President and Members of the House of Delegates of the Minnesota State Medical Association.

Gentlemen: Owing to the fact that the Legislature of the State of Minnesota was not in session during 1924, the activities of your Committee on Public Policy and Legislation has been necessarily limited. We have co-operated with your Committee on Public Health and heartily endorse the recommendations made in their report.

During the sessions of the Legislature of the State of New York we received almost daily bulletins covering the activities of the Committee on Legislation of the Medical Society of the State of New York.

It would seem from these reports that this Society maintains an office at Albany and has a full time man covering the legislature during the entire session. Whether this is feasible in Minnesota or not your Committee does not know, but the subject is worthy of consideration. Telegrams were sent to Governor Smith and Senate Majority Leader James M. Walker at Albany, at the request of Dr. James M. Vanderveer, the Chairman of the Legislative Committee of the New York Society, in the name of this Association, urging the passage of bills relating to the practice of the cults.

A request was received from Dr. W. C. Woodward, Executive Secretary of the Bureau of Legal Medicine and Legislation, of the American Medical Association, request-

ing a transcript of the evidence in a suit brought to test the constitutionality of the Chiropractic law in Minnesota. Interviews with Judge H. D. Dickinson, of Minneapolis, before whom the case was heard, and with Attorney General Hilton, disclosed the fact that there was nothing of value in the evidence and Dr. Woodward was so informed.

Letters have been mailed to the chairmen of the Legislative committees of all County Societies, or to the Presidents or Secretaries of these component Societies, urging them to get in touch with the various aspirants for legislative honors and urge upon them the advisability of informing themselves on medical legislation and to point out to them before they are elected, the necessity for proper regulation of the practice of medicine and surgery.

It is recommended—first, that if possible a full time man be employed during the legislative session, and second, that if any definite legislation is desired by this Association it be formulated at this session and put before the prospective candidates.

COMMITTEE ON PUBLIC POLICY AND LEGISLATION.

THE STATE CANCER COMMITTEE

To the President and House of Delegates of the Minnesota State Medical Society:

Your Cancer Committee begs to submit the report of its activities during the past year.

A review of the discussion precipitated by the report of this Committee at the meeting of the House of Delegates on the first day of the State Society meeting in 1923 presents an interest in the subject of cancer control manifested for the first time. This discussion in itself has served as a stimulus to all members of the Committee to continue in behalf of the State Medical Society the conduct of the educational work as outlined and directed by the American Society for the Control of Cancer.

The constructive criticism offered after the presentation of the 1923 report has resulted in the coalition of the Cancer Committee of the State Medical Society and the State Cancer Committee of the American Society for the Control of Cancer, which enables the Committee to carry on the activities of cancer control under the direction of the State Medical Society. As a result, the activities of this Committee have been conducted in the past year with increasing harmony in the membership of the State Medical Society. As stated in previous reports, it has been the opinion of the State Cancer Committee that it could best serve the interests of the State Medical Society by co-operating with the American Society for the Control of Cancer in its educational campaigns.

The campaign, as outlined in previous years, was again conducted in Minnesota throughout the week of November eleventh to eighteenth in 1923. During that week statewide publicity was given the most salient facts about cancer, through the organization and activities of seventy-six County Cancer Committees. Through these organizations short talks were given, and literature, furnished by the National Society, was read before many audiences, including churches, fraternal organizations, clubs, et cetera. Thirty-one public meetings were held under the auspices of County and District Medical Societies. The newspapers throughout the state contributed liberally of space for

articles dealing with the known facts about cancer, furnished by the National Society. Other activities consisted of five cancer clinics, two radio talks, the showing of the film "The Reward of Courage," and slides in many theaters.

Your Committee believes that educational work should continue and desires the co-operation of the individual members of the State Medical Society. Also, the Committee wishes to follow the suggestions of the House of Delegates in the conduct of its work.

We desire at this time to express our thanks and appreciation to the members of the State Medical Society who have been active in the educational campaigns, particularly those who have acted as County Chairmen, and those who have contributed their time and money in the presentation of public lectures.

Respectfully submitted,

VERNE C. HUNT (Chairman),
Minnesota State Cancer Committee.

REPORT OF THE STATEWIDE PUBLICITY COMMITTEE*

This Committee has been comparatively inactive during the past year.

"The Northwestern Health Journal," which was fostered by the Minnesota Public Health Association and this Committee, is prospering and has an ever increasing list of lay subscribers. The material in the Journal is very high class and is designed to reach the ordinary reading public.

"The Popular Health" is a new magazine now being published by the former editor of the Northwestern Health Journal, and is very much the same type of journal. It is at present in no way sponsored by any medical society or medical group, but the material is being submitted by the editor to various medical men, who are members of this society, and is uniformly good. The editor is anxious to have a committee from the State Association officially censor the material and the advertising in the magazine. This magazine is rapidly reaching a wide circulation,—the editor informs now something over 15,000. It has been sponsored by the dentists of the state to the extent that they are all subscribers, and the dental material is being carefully censored by a group of dentists.

Among other publicity activities of the Committee was the radio broadcasting program. After consultation with the president, Dr. MacLaren, and the counselors, an agreement was entered into with the Dayton Company for the broadcasting of a program of popular medical topics. The program was prepared and the topics were to be given out as under the auspices of the State Medical Society, naming also the County Medical Society of which the man who prepared the talk was a member. In our agreement with the Dayton Company, there were to be no names mentioned, the talk simply being sponsored by the State and County Societies. Owing to suspension of operation by the Dayton Company and the WLAG broadcasting station, the program was not carried out. The Committee would like to know, at this time, the sentiment of the Society on the propriety, the feasibility and value of such a broadcasting

*Inasmuch as this report has not been submitted to the individual members of the committee it is requested by its chairman that any objections or suggestions on the part of committee members be presented to the chairman prior to the meeting.

program. While no advances have been made, it is possible that the new, large broadcasting station, now in the process of construction by the Washburn-Crosby Company, could be induced to give us a place on their program. If the program had been carried out, as intended, the outlines for the various talks would have been submitted to the members of this Society throughout the state,—they being asked to write a popular article on the subject which would either be broadcast from the station by the author or a substitute when the author could not be present. The author's name would not be mentioned, but the article would be published in the state medical journals giving credit to the man who prepared the article.

The Committee was also interested with the Public Health Committee of this Society in promoting interest in the State Fair Health exhibitions. We believe by the showing of a little interest that the whole health program of the State Fair could be put under the auspices of the State Medical Society and the University Medical school, and that it would be a very fine form of publicity and public health work for the Society.

As the publicity work of the Society must largely be carried on under the guise of public health, there is an overlapping duplication in the existence of two committees such as we now have.—the Public Health Committee and the Statewide Publicity Committee. Therefore, it is the desire of the Statewide Publicity Committee that this Committee be discontinued as a separate committee and be continued as part of the Public Health Committee.

N. O. PEARCE, M.D.,

Chairman, Statewide Publicity Committee.

COMMITTEE ON PUBLIC HEALTH

In response to a letter from the chairman of the Statewide Publicity Committee, your committee on April 15, 1924, met with Dean Nicholson and the director of the University Public Health service and the vice president of the Hennepin County Medical Society, to investigate the Public Health Service of the University of Minnesota.

The following statements were made by representatives of the Public Health Service. About 60 per cent of the University students are putting themselves through college, either in whole or in part. Ninety per cent of those who report to the staff would probably not see any physician if it were not for the public health service.

The public health service refers a great many students together with their findings to their family physicians when they live in the Twin Cities, and their policy is to do this in those cases where they feel they are able to pay ordinary fees. They admit that the occasional case able to pay ordinary fees occasionally slips by them, but of what free institution is this not true?

In the judgment of your committee the great work they are doing is that of educating these young people to the value of regular examinations, to the value of reporting themselves early in case of sickness and, last but not least, the thousands of students are graduated educated to the value of regular medicine rather than being advocates of the cults.

As to the good accomplished among the student body there is no question. This is detailed in the April issue this year of MINNESOTA MEDICINE.

Your committee wishes to go on record as heartily indorsing the University Public Health Service.

For the first time the State Medical Association in conjunction with the University of Minnesota has put on a health exhibit at the State Fair. Dr. Wm. O'Brien of the Medical Department has had charge of the work and the medical association has paid the bills. The general scheme was outlined in the September issue of MINNESOTA MEDICINE.

At the 1923 session of the house of delegates, the committee on public health for this year was requested to gather information throughout the United States relative to the points of contact between the medical profession and the public. Forty-nine questionnaires were sent and thirty-three responded. Including Minnesota, we have statistics from thirty-four states.

No. 1. Does legislation initiated by the medical profession meet with a fair degree of co-operation in your state or the reverse?

Excellent, 6 per cent; good, 14 per cent; fair, 40 per cent; poor, 40 per cent.

No. 2. Are the medical men of your state organized into legislative committees with reference to proposed legislation?

In 9 states, special organizations; in 24 states, handled by the state committee; in 1 state, no organization.

No. 3. Does your State Association or public health agency publish a journal devoted to medical and public health matters for the laity?

Six states do this, including Minnesota, and one state has a tuberculosis journal.

No. 4. Does your State Association or any component medical society approve or conduct systematic radio talks?

Kentucky, Ohio, Washington (state), Pennsylvania and Wisconsin do this. Approval of the idea expressed by Georgia, Iowa, Texas, Nevada. Minnesota hopes to begin such a program this fall.

No. 5. Have you a public health league or similar organization which develops contact between the profession and the public?

Fifteen states have, including Minnesota.

No. 6. Have you a state hospital for medical and surgical cases and if not through what channels are the poor in your rural communities cared for?

Twelve, including Minnesota, answer yes. Sixteen provide community care only. Six have an insane hospital or none.

No. 7. Are your hospital facilities for indigent tuberculous cases ample?

Yes, 10; fair, 10; no, 10. No tuberculous cases requiring hospitals, 2.

No. 8. Grouping together osteopaths and chiropractors, what is their percentage to medical men?

Unknown, 7. The balance of the states run all the way from 3 per cent to 50 per cent in Wisconsin. In Minnesota the proportion is about 20 per cent.

No. 9. What are your state activities along the lines of child welfare?

Every state that answered is active in this line.

No. 10. Any other information showing points of contact between the medical profession and the public would be greatly appreciated.

Five states have lecture programs; one state offers occasional lectures, and one gives state clinics. Kentucky, Georgia and Wisconsin have systematic public press articles.

If we analyze conditions in Minnesota from the standpoint of contact between the medical profession and the laity we find some satisfactory conditions as well as the reverse. Co-operation on the part of the state legislature is very far from what we could desire. Local county society legislative committees were organized two to three years ago and should be continued. The committee on legislation of the state association is helpless without general co-operation throughout the state. These committees should be active in the pre-election period.

We find two lay journals in Minnesota devoted to public health matters—one published by the Minnesota Public Health Association—the Northwest Health Journal, with a subscription list of over 10,000. This journal deserves the support of every physician in the state and should be in every doctor's waiting room. The second journal is the Popular Health Magazine, which is privately owned and exists for private gain.

The Minnesota Public Health Association deserves more than passing comment.

In 1903, the Minnesota Anti-Tuberculosis Association was organized. In 1907 they had a paid executive secretary. In 1915 the name was changed to the Minnesota Public Health Association. It is financed entirely through the sale of Christmas seals and this income this year was over \$100,000. Their activities include:

Clinics, tuberculosis, pediatrics and public health.

Tuberculosis clinics are conducted by county sanatoria men.

Pediatric clinics by specialists whose expenses are paid by the association. The public health clinic consists of a doctor and nurse who travel over the state in a Ford truck provided the counties have sold enough Christmas seals to pay expenses.

Four public health nurses were in the field this summer.

Health exhibits are loaned as occasion demands. They try and have them at local county fairs as well as at the state fair. They also send a health clown to these fairs.

Dr. Lohead will give health lectures anywhere in the state.

They distribute much public health literature free of charge. They publish at a loss the Northwestern Health Journal, with a circulation of over 10,000.

The matter of radio broadcasting in Minnesota on public health matters by the medical profession has been a storm center of discussion. The consensus of opinion is that the name of the speaker shall not be announced unless he is a full time teacher or public health worker and not engaged

in the active practice of medicine. Your committee is convinced that to allow a relatively small number of active practitioners, whose names are announced over the radio, to broadcast public health talks, would create bad feeling and is not good policy. Five states or county societies broadcast public health talks and four states expressed approval of the plan. Your committee warmly endorses the plan if properly safeguarded. The two stations in Minneapolis have discontinued, but if either of them reopens, broadcasting will probably be done under the auspices of the State-wide Publicity Committee. There are in our state 128 nurses doing public health work exclusive of the Twin Cities and Duluth. There are forty-six county nurses and thirty-seven counties have no nurse. These nurses are paid by various agencies—the local county commissioners, school boards, Red Cross or Minnesota Public Health Association. Olmstead county has a county health nurse, infant welfare nurse, a county maternity nurse, and a school nurse.

Thirty-seven counties of the state support fourteen county tuberculosis sanatoria. This is in addition to Walker.

Minnesota is one of the twelve states out of thirty-four which are equipped to care for the indigent sick, both general and tuberculous.

Some interesting features of work along these lines have been worked out in other states. The Ohio public health association is the chief medium of contact between the profession and the laity. In addition, they have a public health federation including dentists, druggists, nurses, hospitals, the public health association and physicians.

In Kentucky the county medical societies work in close co-operation with the Bureau of Child Hygiene and the State Board of Health. All local clinics are under supervision of the county medical societies. The State Medical Association and the State Board of Health are closely co-ordinated. The State Health Officer is the Secretary of the State Medical Association, and therefore the state association guides the activities of the State Board of Health, which is the legal arm of the profession and is so recognized by the legislature and the public.

In Colorado the Denver City and County Medical Society conducts monthly public health lectures. They have a Colorado association for the protection of public health composed of many prominent laymen as well as doctors.

Massachusetts: "It is only a few months ago that our society first took up this matter of contact between the profession and the public and we have spent most of our time investigating the possibilities. So far we are depending upon lectures which we insist shall be constructive, not argumentative, and the block material for the county newspapers. We are making contact through parent-teachers' associations, women's clubs, labor unions and any place where they may want a lecturer. Each district society is asked to hold an occasional meeting in their district."

In Georgia they have a statewide health association composed of the state chamber of commerce, bankers, railroads and the medical profession. Also a state health council composed of medical associations, Red Cross, the tuberculosis association, Kiwanians, Rotarians, women's clubs, state agricultural society and physical education association.

Texas: The medical profession is raising a considerable

sum of money for a publicity campaign in order to gain public and legislative support.

From a study of the answers received, one is impressed with the general recognition of the idea of the advisability of our profession developing contact with the public along public health lines. The basic underlying principle is to strive for an intelligent public viewpoint toward the medical profession.

Individual members of your committee have repeatedly had the idea of effort along these lines held up to ridicule by the high grade medical men. They say that we are not in a position to do anything as long as we harbor crooks and abortionists and ignorant doctors in our medical societies and allow them to practice medicine.

They say get rid of them first and we can present a clean front to the public and propaganda will not be necessary. Then they add, "How are we going to do it?"

Such types exist in all professions. Your committee believes that the same principle that governs in the acceptance of a life insurance applicant, namely, a confidential report on the moral hazard involved, should also govern in the selection of candidates by the medical schools—namely, a confidential report on character. Those who cannot measure up to established standards should be rejected.

However, if we allow the public to rate the entire medical profession by its relatively few crooks we commit a gross injustice to ourselves.

RECOMMENDATIONS

(1) That local committees on legislation be continued in every county society in the state.

(2) That local committees on public health in every county society take an active interest in all local public health matters.

(3) That radio broadcasting on public health matters be undertaken as soon as possible under the auspices of the statewide publicity committee—that such talks be announced as being given under the auspices of the Minnesota State Medical Association and the _____ County Medical Society, but that the name of the speaker shall not be announced if he is engaged in the active practice of medicine.

(4) That the Minnesota Public Health Association be asked to broaden the scope of their work to include the sending of selected articles on public health to the newspapers of the state at regular intervals and to obtain the newspapers' co-operation for their publication.

(5) That the association indorse the Northwestern Health Journal and permit the management to state that it is the official journal for the public of the Minnesota State Medical Association.

(6) That the Secretary of the Minnesota State Medical Association transmit to the Board of Regents of the University of Minnesota, the recommendation of their house of delegates that in addition to educational requirements to the medical school that the character of applicants for admission be ascertained by confidential reports and that those not measuring up to a proper standard be rejected.

(7) That the state medical association continue their part in the State Fair Public Health Exhibit.

COMMUNICATIONS

Kansas City, Mo.,

August 30, 1924.

DEAR EDITOR:

A nationwide movement for improved conditions in maternal welfare is being inaugurated through the combined efforts of a joint committee representing the American Gynecological Society, the American Child Health Association, and the American Association of Obstetricians, Gynecologists, and Abdominal Surgeons.

An appeal is being made to the Secretaries of the State Medical Associations to enlist the co-operation of their members and also of the constituent County Medical Societies to stress the subject of obstetrics in the programs of their meetings and try to have more papers and discussions on the topics vital to this most essential branch of our work.

The reason for the propaganda is that recent statistics are published showing a deplorably high mortality in maternity work in our country. A Washington report gives the United States the unenviable position of third from the highest death rate in both sepsis and eclampsia among the seventeen civilized nations of the world. These two accidents are almost absolutely preventable. Among the reports from sections where pre-natal care is taught and where aseptic care observed in labor the mortality is reduced one-third to one-half the average in the same region.

So many other features, while not so tragic, demand reform in obstetrics that the committee hopes within five years that not only the mortality of mothers and children may be reduced just as the profession has cut down the death rate in typhoid fever, tuberculosis and diphtheria in recent decades; but also that obstetrics may be again placed on the plane with internal medicine and surgery, a dignity which it formerly occupied in the colleges and in the profession, as one of the three great branches of the healing art.

This is a work of education, and it demands the co-operation of teachers and specialists in obstetrics, general practitioners, nurses, and the general public, to accomplish so ambitious a program.

A copy of the Annual Report to the American Association of Obstetricians, Gynecologists, and Abdominal Surgeons is sent under separate cover detailing some of the conditions found and showing the more hopeful outlook for the future.

OBITUARY

DR. JAMES B. WHITE

Dr. James B. White, of Belle Plaine, Minnesota, died at the age of 60 years at the Miller hospital, St. Paul, Saturday morning, August 30, 1924, following an illness of several weeks' duration.

James B. White was born in New York City on August 6th, 1864. When a child of three years his father died and shortly afterward the family moved to Belle Plaine. He grew to manhood in that locality and for a few terms taught school. He later entered the medical school at the University of Minnesota, from which institution he graduated in 1891. The same year he moved to Montgomery to practice medicine. He remained there until October, 1901, when he went to Faribault and specialized in surgery. In the spring of 1906 he again returned to Montgomery and followed his profession until February, 1912, when he returned to his early home in Belle Plaine.

He is survived by his wife, two sons, Robert, of Duluth, and Frank, of St. Paul, two sisters, Mrs. Dennis Connelly, of St. Thomas, and Mrs. H. B. Conlon, of Belle Plaine. Two stepbrothers, M. O'Brien, of Belle Plaine, and John O'Brien, of St. Paul, also survive.

The following tribute is paid Doctor White in the columns of a home paper:

"Doctor White was not only one of our leading physicians but was almost a native son, having come to Belle Plaine in his early childhood. He was widely known through Scott, LeSueur and Rice Counties. He stood high in his profession as a conscientious physician and high in the community as an exemplary citizen. During his practice of more than thirty years he alleviated pain for hundreds and stayed the approach of the Grim Reaper in many homes, yet was fated to go himself when little past the meridian of life. He was of that splendid type of country doctor that responded to every call to rich and poor alike, in every kind of weather, under every adverse condition."

DR. ROBERT H. MULLIN

Notice has been received of the death of Dr. Robert Hyndman Mullin, formerly Associate Professor of Pathology and Bacteriology, Medical School, University of Minnesota, and Director, Laboratory Division, Minnesota State Board of Health.

Dr. Mullin has resided in Vancouver, British Columbia, for several years. He was pathologist for Vancouver General Hospital and connected with the University of British Columbia.

Death was sudden, from cerebral hemorrhage, and occurred at his home, 821 Broughton Street, Friday, August 29, 1924.

DR. JOHN C. NELSON

Few men in our profession have enjoyed to such an extent the esteem, both of his professional brethren and the laity, as did Doctor John C. Nelson. Dr. Nelson was one of the most thorough and ardent Americans the writer has ever known. It was almost dangerous for one to laud this country's enemies or speak disparagingly of any of its institutions within his hearing. Although he was knighted by the King of Denmark for his efforts in behalf of the people from the land of his birth, this recognition should properly have come from us as all his efforts were bent toward educating these foreign born future citizens of the United States in the precepts of pure Americanism.

Dr. Nelson's life is a perfect example for a foreign-born boy landing on the shores of this country to follow. He was a well-educated competent physician, devoted to his work and a man who always had time to accept many times more than his share of the responsibility incumbent upon citizens of this nation and members of this community.

Dr. Nelson was born in Copenhagen in 1847. He came to this country when he was 18 years of age, with his brother and a boyhood chum. He had heard of a Danish settlement at Beloit, Wisconsin, and he came directly from New York to this community. He stayed there but a short time when he went to Fillmore county, Minnesota, working as a clerk in small villages and finally becoming a drug clerk in the town of Lanesboro, Fillmore county. While at this work he became interested in the practice of medicine and began his studies in the Keokuk Medical College. He came to St. Paul in 1879 where he began to practice. Dr. Nelson was coroner of Ramsey county during the years from 1896 to 1900, having served two terms. He had been Danish Vice Consul for this district for the 28 years previous to his death, which occurred March 3, 1924. He had been the examiner for the Aetna Life Insurance Company for 30 years previous to his death. About ten years ago he was knighted in the Order of Dannebrog by the King of Denmark for faithful and efficient service as Danish Vice Consul in this country. Before Dr. Nelson's death he was the second oldest Scottish Rite Mason in the State of Minnesota. He was a member of Damascus Commandery of the Knights Templar, and Osman Temple of the Shrine. He was the first president of the St. Paul Cycle Path Association and for many years was an ardent devotee of bicycling. He was also the first president of the St. Paul Garden Club and was one of our leading amateur authorities on horticulture.

Fifty-two years ago Dr. Nelson was married to Hansina Jensen. He is survived by his widow; three sons and one daughter, Dr. M. O. Nelson, Dr. Louis A. Nelson, Dr. Edgar E. Nelson, and Miss Anna Nelson.

H. B. ZIMMERMAN, M.D.

REPORTS AND ANNOUNCEMENTS OF SOCIETIES

MINNESOTA STATE MEDICAL MEETING

The annual meeting of the Minnesota State Medical Association will take place in St. Cloud, Wednesday, Thursday and Friday, October 8, 9 and 10, 1924. A program has been mailed to each member.

The Council meets at 10 A. M. and the House of Delegates at 2 P. M. on October 8, in the Knights of Columbus quarters adjoining the Breen Hotel. The second meeting of the House of Delegates will be on the second day, October 9, instead of on the last day of the convention, as formerly. All information can be obtained at the Breen Hotel, which is to be headquarters.

The scientific program begins Thursday, October 9, at 8:30 A. M., the Surgical section meeting in the Sherman Theatre and the Medical Section in the Knights of Columbus Hall, both adjoining the Breen Hotel. The General Sessions will meet in the Sherman Theatre each afternoon at 2 P. M.

Physicians are particularly urged to bring their ladies for the entertainment of whom special efforts have been made. Auto rides through the quarries and to the paper mills and State reformatory and opportunities for golf will be provided. The dance Thursday evening will hardly be a success unless the ladies attend. There will be no wall flowers at St. Cloud.

Dr. C. B. Lewis is general chairman of the local committees on arrangements.

Officers of the Association are:

President—Archibald MacLaren, M.D., St. Paul
First Vice President—E. T. Sanderson, M.D., Minneota
Second Vice President—F. J. Hirschboeck, M.D., Duluth
Third Vice President—C. W. Bray, M.D., Biwabik
Secretary—Carl B. Drake, M.D., St. Paul
Treasurer—F. L. Beckley, M.D., St. Paul

PROGRAM OF THE MINNESOTA STATE MEDICAL ASSOCIATION

Fifty-sixth Annual Session
October eighth to tenth
1924

THURSDAY MORNING—OCTOBER 9TH
8:30 A. M.

MEDICAL SECTION

E. L. TUOHY, M.D., Chairman
CHARLES N. HENSEL, M.D., Secretary
Knights of Columbus Hall

1. Differential Diagnosis of Pulmonary Disease—M. George Milan, M.D., Warren
Discussion by George Douglas Head, M.D., Minneapolis; Walter J. Marley, M.D., Minneapolis
2. Artificial Pneumothorax in Acute Lung Abscess—Everett K. Ceer, M.D., St. Paul
Discussion by W. S. Lemon, M.D., Rochester; J. N. Myers, M.D., Minneapolis
3. Liver Functional Studies in Clinical Jaundice—Carl Hartley Greene, M.D., Rochester

4. Liver Functional Studies in Experimental Jaundice—A. M. Snell, M.D., Rochester
Discussion on both papers by Henry L. Ulrich, M.D., Minneapolis; Leonard G. Rowntree, M.D., Rochester; H. W. Walters, M.D., Rochester
5. Diabetes in Children—F. W. Schlutz, M.D., Chief Department of Pediatrics, University of Minnesota, Minneapolis
Discussion by N. O. Pearce, M.D., Minneapolis; O. W. Rowe, M.D., Duluth
6. Practical Electrocardiography—Harold E. Richardson, M.D., St. Paul
7. The Electrocardiogram in the Management of Heart Disease—E. T. F. Richards, M.D., St. Paul
Discussion by R. Edwin Morris, M.D., St. Paul; F. A. Willius, M.D., Rochester; M. H. Nathanson, M.D., Minneapolis

SURGICAL SECTION

A. C. STRACHAUER, M.D., Chairman
VERNE C. HUNT, M.D., Secretary
Sherman Theatre

1. The Treatment of Severe Injuries of the Scalp—Orville N. Meland, M.D., Warren
Discussion by A. W. Adson, M.D., Rochester; W. L. Burnap, M.D., Fergus Falls; A. A. Law, M.D., Minneapolis
2. Obstructive Jaundice and Studies in Liver Function—H. Waltman Walters, M.D., Rochester
Discussion by A. L. Cameron, M.D., Minneapolis; A. C. Strachauer, M.D., Minneapolis; A. A. Zierold, M.D., Minneapolis
3. Foreign Proteins as Therapeutic Agents in the Treatment of Acute Ocular Inflammation—John F. Fulton, M.D., St. Paul
Discussion by Paul Berrisford, M.D., St. Paul; W. L. Benedict, M.D., Rochester; W. R. Murray, M.D., Minneapolis; Carl Larsen, M.D., St. Paul
4. Preoperative Treatment of the Prostatic—Gilbert J. Thomas, M.D., Minneapolis
Discussion by H. C. Bumpus, M.D., Rochester; Oscar Owre, M.D., Minneapolis; Edward Bratrud, M.D., Warren
5. Acute Osteomyelitis in Children—Carl C. Chatterton, M.D., St. Paul
Discussion by M. H. Tibbetts, M.D., Duluth; H. T. Jones, M.D., Rochester; P. W. Giessler, M.D., Minneapolis; C. A. Reed, M.D., Minneapolis
6. Perforating Gastric Ulcer—P. E. Stangl, M.D., St. Cloud
Discussion by H. C. Cooney, M.D., Princeton; H. B. Zimmerman, M.D., St. Paul; C. H. Mayo, M.D., Rochester; E. M. Jones, M.D., St. Paul
7. Consideration of Various Abdominal Symptoms and Findings in Diagnosis—William R. Bagley, M.D., Duluth
Discussion by J. P. Schneider, M.D., Minneapolis; J. A. Johnson, M.D., Minneapolis; Robert Earl, M.D., St. Paul

THURSDAY AFTERNOON—OCTOBER 9TH

2:00 P. M.

General Session
Sherman Theatre

CANCER SYMPOSIUM

1. Carcinomata as Shown by Paper Models Reconstructed From Serial Section—Margaret Warwick, M.D., St. Paul
2. Some Unusual Pathologic Features Concerning Cancer—Harold Robertson, M.D., Rochester
3. The Destructive and Constructive Surgery of Malignancy—Harry P. Ritchie, M.D., St. Paul
4. The Relative Value of Surgery and Radiotherapy—William J. Mayo, M.D., Rochester
5. What the Laity Should Know About Cancer—William A. O'Brien, M.D., Minneapolis

FRIDAY MORNING—OCTOBER 10TH

8:30 A. M.

MEDICAL SECTION

Knights of Columbus Hall

1. Amebiasis—T. B. Tuttle, M.D., Veterans' Bureau
Discussion by A. J. Chesley, M.D., State Board of Health; W. L. Pollock, M.D., Rochester; Margaret Warwick, M.D., St. Paul
2. Hemorrhagic Purpura—H. Z. Giffin, M.D., Rochester
Discussion by S. Marx White, M.D., Minneapolis; J. P. Schneider, M.D., Minneapolis
3. Some Observations Concerning Tic Douloureux After Sixteen Years' Experience—Charles R. Ball, M.D., St. Paul
Discussion by A. S. Hamilton, M.D., Minneapolis; J. C. Michael, M.D., Minneapolis
4. The Role of Infections in Nervous Disease—W. H. Hengstler, M.D., St. Paul
Discussion by Henry W. Woltmann, M.D., Rochester; A. S. Hamilton, M.D., Minneapolis
5. Diathermy in Vascular Circulatory Disturbances and Arthritis—A. E. Flagstad, M.D., St. Paul
Discussion by P. G. Boman, M.D., Duluth; G. S. Wat-
tam, Warren; G. E. Brown, M.D., Rochester
6. Cutaneous Picture of Late Syphilis—Paul A. O'Leary, M.D., Rochester
Discussion by S. Sweitzer, M.D., Minneapolis; A. H. Schwartz, M.D., Duluth
7. Diseases of the Pancreas; Discussion of the Important Symptoms and Findings with Report of Cases—Moses Barron, M.D., Minneapolis
Discussion by George Douglas Head, M.D., Minneapolis

SURGICAL SECTION

Sherman Theatre

1. The Silent Antrum—W. L. Burnap, M.D., Fergus Falls
Discussion by H. I. Lillie, M.D., Rochester; Horace Newhart, M.D., Minneapolis; J. D. Lewis, M.D., Minneapolis; J. T. Schlesselman, M.D., Mankato
2. Surgical Accidents in Simple Inguinal Hernioplasty—Emil C. Robitshek, M.D., Minneapolis
Discussion by J. C. Masson, M.D., Rochester; G. G. Eitel, M.D., Minneapolis; Gustav Schwyzer, M.D., Minneapolis; A. R. Colvin, M.D., St. Paul

3. Arthroplasties—M. S. Henderson, M.D., Rochester
Discussion by Emil Geist, M.D., Minneapolis; Wallace Cole, M.D., St. Paul; C. C. Chatterton, M.D., St. Paul
4. Fractures of the Spine—Emil F. Geist, M.D., Minneapolis
Discussion by M. S. Henderson, M.D., Rochester; C. B. Lewis, M.D., St. Cloud; A. E. Wilcox, M.D., Minneapolis; C. A. Reed, M.D., Minneapolis
5. Relative Merits of the Different Surgical Procedures for Duodenal Ulcer—D. C. Balfour, M.D., Rochester
Discussion by A. C. Strachauer, M.D., Minneapolis; H. P. Ritchie, M.D., St. Paul; A. T. Mann, M.D., Minneapolis; T. L. Chapman, M.D., Duluth
6. Tracing Infections in a Surgical Service—Arthur N. Collins, M.D., and Fred Ritz, Bacteriologist, Duluth
Discussion by Walter E. Sistrunk, M.D., Rochester; William C. Carroll, M.D., St. Paul; A. C. Baker, M.D., Fergus Falls
7. Anesthesia in Goiter Operations at the Schmieden Clinic—C. Alexander Hellwig, M.D., St. Cloud (temporarily), Frankfort-am-Main, Germany

FRIDAY AFTERNOON—OCTOBER 10TH

2 P. M.

General Session
Sherman Theatre

1. Installation of Officers
2. The Behavior of the Testes Under Varying Experimental Conditions and the Function of the Scrotum: Transplantation Cryptorchidism and Vasectomy—Carl R. Moore, M.D., Department of Zoology, University of Chicago, Chicago, Illinois
3. Child Guidance—Lawson G. Lowrey, M.D., Minneapolis

LYMANHURST AND PARKVIEW STAFF MEETING

The regular monthly meeting of the Lymanhurst and Parkview medical staffs will be held at Lymanhurst School, 1800 Chicago Avenue, Minneapolis, Tuesday evening, October 28, at 7:00 o'clock.

Following is the program for the evening:

"Recent Literature on Tuberculosis in Infancy and Childhood," Dr. David M. Siperstein.

"Types of Tuberculosis at Different Ages," Dr. C. A. Stewart.

"Biological Tests in Infancy and Childhood," Dr. Cecile Moriarty.

"Bronchiectasis in Childhood," Dr. R. W. Morse and Dr. H. Lippman.

All persons interested in tuberculosis are invited to attend these meetings and participate in the discussions.

MINNESOTA ACADEMY OF MEDICINE

MEETING OF SEPT. 10, 1924

The Minnesota Academy of Medicine held its annual meeting at the Town and Country Club on Wednesday evening, September 10, at 8 P. M. The meeting was called to order by the President, Dr. A. S. Hamilton. There were 27 members present.

The minutes of the May meeting were read and approved.

The annual reports of the Secretary and Treasurer were read and accepted.

The annual election was held and the following officers were elected:

President—Harry P. Ritchie, M.D., St. Paul

Vice President—Henry L. Ulrich, M.D., Minneapolis

Secretary-Treasurer—John Eldon Hynes, M.D., Minneapolis (re-elected)

Dr. John F. Fulton, first president of the Academy, and Dr. S. Marx White, escorted the newly elected president to the Chair.

The retiring President, Dr. Hamilton, then read his President's address, entitled "Historical Survey of the Academy of Medicine."

The meeting adjourned.

JOHN E. HYNES,
Secretary.

AMERICAN ACADEMY OF OPHTHALMOLOGY AND OTOLARYNGOLOGY

At the twenty-ninth annual meeting of the American Academy of Ophthalmology and Otolaryngology, held in Montreal, September 15 to 20, Dr. Horace Newhart, of Minneapolis, was elected president. The following Northwestern Fellows were present: From Minneapolis, Dr. Howard S. Clark, Dr. Wm. R. Murray, Dr. Horace Newhart, Dr. John A. Pratt, Dr. James S. Reynolds; from St. Paul, Dr. H. W. Grant; from Hibbing, Dr. W. E. Morsman; from Rochester, Dr. W. L. Benedict and Dr. Burt E. Hempstead; from Aberdeen, S. D., Dr. Robt. D. Alway, and Dr. A. E. Johnson from Watertown, S. D.

Dr. Carl C. Wold, of St. Paul, was elected a Fellow, and Dr. E. J. Brown, of Minneapolis, was made a Life Fellow. The next meeting will be held in Chicago.

OF GENERAL INTEREST

Dr. H. B. Aitkens, Le Sueur Center, spent the month of September in northern Wisconsin.

Dr. Joseph F. Borg has opened offices at 636 Lowry Bldg., St. Paul, for the practice of medicine.

Dr. Josephine Tofte has moved from Minneapolis to Fisher, where she was formerly located.

Dr. D. R. Hastings of Duluth has recently moved to Oak Terrace for the practice of his profession.

Dr. Walter G. Benjamin, formerly with the Mayo Clinic, Rochester, is now located at Pipestone, Minn.

Dr. F. G. Hedenstrom has opened offices at 218 Lowry Bldg., St. Paul, for the practice of his specialty, Pediatrics.

Dr. Karl E. Kretschmar, formerly of Minneapolis, has located in Los Angeles, Cal., for the practice of his profession.

Dr. E. Eric Larson of the Mayo Clinic, Rochester, is now associated in practice with the Woodland Clinic, Woodland, Cal.

Dr. L. A. Calkins has moved from Minneapolis to Charlottesville, Virginia, where he is associated with the University of Virginia.

Dr. Leo G. Rigler, Minneapolis, is now in the East where he is taking a course in advanced work in Roentgenology. Dr. Rigler expects to return to Minneapolis the first of next year.

Dr. Clyde E. Gray, formerly of Rush City, is now associated in practice with Dr. G. M. Edwards, Denver, Colorado. Dr. Gray disposed of his practice at Rush City to Dr. A. E. Holmes last spring, following which he took up post-graduate work in surgery in Chicago and New York. Dr. Gray had practiced in Rush City for the past eighteen years.

The thirty-seventh annual meeting of the North Dakota State Medical Association was held in Bismarck, September 10 and 11, 1924. Among the visitors from Minnesota who took part in the program were Drs. Theodore Bratrud, E. L. Tuohy, E. S. Judd, W. R. Ramsey, W. A. Jones and S. G. Sweitzer.

Reports indicate that Syracuse, N. Y., is having more than its share of infantile paralysis this summer. Six cases were reported in June and thirty-two in July. It is interesting to note that the initial cases were among Italian children, as was the case in the 1916 epidemic in New York City and the 1921 epidemic in Utica.

A recent survey made by a group of University of Minnesota students of 309 households showed that 40 to 48 per cent of the members read the health news published by newspapers and that about half of them follow the health instructions. About 25 per cent of the households studied were those of mechanics and laborers.

Exercises for the laying of the cornerstones of Todd Memorial Hospital and the Cancer Institute on the University Campus, Minneapolis, were held at 2 P. M., Wednesday, October 1, 1924. President Coffman, of the university, presided and addresses were delivered by Dr. Arthur Dean Beban, of Chicago, and Dr. Edward L. Tuohy, Duluth.

Alumni of the University Medical College, Kansas City, Mo., will hold a reunion banquet, Wednesday, October 15, 1924, at 6:30 P. M. in the banquet room of the Kansas City Athletic Club, 11th and Baltimore, Kansas City, Mo. Dur-

ing the noon hour of the same day the various classes from 1882 to 1913 inclusive will hold individual class reunion luncheons. The reunion banquet is a part of the program of the Kansas City Clinical Society, which will convene in Convention Hall, Kansas City, Mo., October 13 to 18, 1924.

In recognition of the far-reaching developments of bronchoscopy in the diagnosis and treatment of diseases of the lungs and of esophagoscopy and gastroscopy in the diagnosis and treatment of diseases of the esophagus and stomach, the Board of Trustees and Faculty of the Jefferson Medical College have created a new chair, to be known as the Department of Bronchoscopy and Esophagoscopy. Dr. Chevalier Jackson, formerly Professor of Laryngology in the Jefferson Medical College, has been elected to the professorship of the new department. Dr. Fielding O. Lewis has been elected to fill the Chair of Laryngology vacated by Dr. Jackson.

NEW AND NON-OFFICIAL REMEDIES

The following have been accepted by the Council on Pharmacy and Chemistry:

COLEMAN AND BELL COMPANY:

Gentian Violet Improved Medicinal

HYNSON, WESTCOTT AND DUNNING:

Meroxyl

Meroxyl Tablets-H. W. and D.

JENSEN-SALSBERY LABORATORIES:

Rabies Vaccine (Human) Phenol Killed

ELI LILLY AND COMPANY:

Oridine

Oridine Tablets

H. A. METZ LABORATORIES:

Silver-Salvarsan. 0.6 gm. ampules

NATIONAL ANILINE AND CHEMICAL COMPANY:

Gentian Violet Medicinal—"National"

PARKE, DAVIS AND COMPANY:

Diphtheria Toxin-Antitoxin Mixture, 0.1 L+-P. D. and Co.

E. R. SQUIBB AND SONS:

Antistreptococcic Serum-Squibb, packages one 10 cc. syringe

Antistreptococcic Serum-Squibb, packages one 50 cc. vial

Antistreptococcic Serum Rheumatic-Squibb, packages one 20 cc. vial

Antistreptococcic Serum Rheumatic-Squibb, packages one 50 cc. vial

Diphtheria Toxin Antitoxin Mixture (New Formula), packages thirty 1 cc. ampules

Sulpharsphenamine-Squibb, 1 gm. ampules

Sulpharsphenamine-Squibb, 3 gm. ampules

FREDERICK STEARNS AND COMPANY:

Insulin-Stearns Quadruple Strength

WILSON LABORATORIES:

Ampules Pituitary Solution-Wilson, 0.5 cc.

NONPROPRIETARY ARTICLES:

Thiosinamine

Gentian Violet Medicinal

NEW AND NON-OFFICIAL REMEDIES

Holocaine Ointment-M. E. S. Co.—Composed of holocaine (see New and Non-official Remedies, 1924, p. 35) 1 per cent, water 1 per cent, wool fat and petrolatum 98 per cent. Put up in collapsible tubes for application to the eye. Manhattan Eye Salve Co., Louisville, Ky. (Jour. A. M. A., Aug. 2, 1924, p. 357.)

Silver-Salvarsan, 0.6 Gm. Ampules.—Each ampule contains silver-salvarsan (see New and Non-official Remedies, 1924, p. 54) 0.6 gm. H. A. Metz Laboratories, New York.

Diphtheria Toxin-Antitoxin Mixture 0.1 L+.—A diphtheria toxin-antitoxin mixture (see New and Non-official Remedies, 1924, p. 299), each cc. representing 0.1 L+ dose, of diphtheria toxin, neutralized with the required amount of antitoxin. It is marketed in packages of three bulbs, each containing 1 cc.; also in vials containing 20 cc. Parke, Davis and Co., Detroit. (Jour. A. M. A., Aug. 16, 1924, p. 508.)

PROPAGANDA FOR REFORM

Camphor in Oil in Heart Failure.—Marvin and Soifer have studied the effects of camphor in oil as a cardiac stimulant. They failed to secure evidence of any action on heart rate, respiration, blood pressure, vital capacity or the general clinical condition in which digitalis is frequently promptly effective. Henceforth, the burden of proof that camphor in oil has a rational place in the treatment of congestive heart failure rests with its advocates. All others may well hesitate to place their trust in a drug that seems to have given more promises than therapeutic performances. (Jour. A. M. A., August 2, 1924, p. 362.)

More Misbranded Nostrums.—The following products have been the subject of prosecution by the federal authorities charged with the enforcement of the Food and Drugs Act: DeWitt's Kidney and Bladder Pills (E. C. DeWitt and Co.), consisting essentially of methylene blue, potassium nitrate and plant material, including a volatile oil such as juniper oil. Foster's Backache Kidney Pills (Porto Rico Drug Co.), consisting of potassium nitrate, rosin, fenugreek, uva ursi and an essential oil such as juniper. Glycofostina (Henry S. Wampole Co., Baltimore), consisting essentially of strychnin sulphate, sodium calcium and potassium glycerophosphate, alcohol and water. (Jour. A. M. A., Aug. 2, 1924, p. 375.)

Rectal Administration of Digitalis.—Digitalis is absorbed rapidly and fairly uniformly from the alimentary tract of man, although some substances in the digitalis group, notably strophanthus products, are unsuited for oral administration. However, nausea, vomiting or surgical operations may sometimes interfere with the use of digitalis by mouth. For such emergencies digitalis may be satisfactorily administered by rectum. In many patients with auricular fibrillation, the results have been rapid and beneficial. Rectal digitalis therapy is not intended to supplant the well-established oral method of administration, but rather to be used as an emergency measure when the customary mode of introduction is not feasible. (Jour. A. M. A., Aug. 9, 1924, p. 446.)

Anaphylactoid Phenomena and Modern Therapy.—Anaphylaxis is that state of hypersusceptibility to a given substance which has been induced by a previous injection of the same substance. The reaction is limited to substances of a protein nature. A considerable variety of chemically

unrelated substances may produce "anaphylactoid" symptoms after intravenous injection by virtue of their causing occlusion of the pulmonary capillaries by thrombosis or by agglutinated corpuscles or platelets. Some of the substances which may produce anaphylactoid phenomena have been widely proposed for intravenous therapy, including a variety of "colloidal" solutions of iron, mercury, arsenic, antimony and protein, as well as extracts of animal tissues. In consideration of the possibility of anaphylactoid reactions being induced by such substances, it is well to reiterate that there seems to be little, if any, justification for the intravenous administration of such agents as hexamethylenamin, sodium iodid, and sodium salicylate, because their systemic effects are readily obtained by oral administration. (Jour. A. M. A., Aug. 23, 1924, p. 614.)

Scarlet Fever Toxin.—Scarlet fever toxin has been furnished by the John McCormick Institute to some city and state health departments. Physicians inquiring for this material should apply to their local health department. There is an increasing demand for standardized toxin that the Drs. Dick believe should be met; however, because the toxin must be standardized on human beings, the commercial companies are going to find it difficult to standardize accurately. (Jour. A. M. A., Aug. 30, 1924, p. 705.)

Chlorin Inhalations in Respiratory Affections.—Numerous devices have been advanced for the inhalation of chlorin gas. Several municipal health departments have installed treatment chambers where such devices are undergoing extensive experimentation. It is impossible to say if the virtues of the method have been demonstrated, and it must be considered in an experimental stage. The indications are that chlorin inhalations will not produce bacterial sterilization of the mucous membrane, although they seem to reduce the number of bacteria found on the tissues. The duration of an adequate treatment, the concentration of gas to be used, the methods by which the gas is to be produced, and similar factors are still the subject of experimentation. (Jour. A. M. A., Aug. 30, 1924, p. 691.)

Fatal Anaphylaxis From Hemostatic Preparations.—Recently a death was reported which was caused by the injection of a hemostatic preparation. It was discovered afterwards that the patient was a sufferer from asthma and that the attacks were elicited even by the mere approach of a horse. Because of the importance of determining the anaphylactic possibilities of the various blood coagulants, the Council on Pharmacy and Chemistry had specimens of the following preparations examined: Coagulen-Ciha, Fibrogen-Merrell, Hemagulen-Lilly, Kephalin-Armour, Hemostatic Serum Lapenta (Hemoplastin)? P. D. and Co., Thromboplastin-Lederle, Thromboplastin-Squibb, Thromboplastin Hypodermic-Squibb, Thromboplastin Solution-Armour, Precipitated Horse Serum (Coagulose)-P. D. and Co. It was found that all of the specimens contained animal protein (in most cases horse or beef protein was present). In most cases the labels and descriptive literature did not state the precise nature of the coagulant. Since blood coagulants are usually administered as an emergency measure, physicians may overlook the danger and introduce these foreign proteins into a hypersensitive person. The Council recommends that all hemoplastic preparations be labeled to show the composition of the product, the character of the

protein present, and to contain information which will cause the physician to inquire into the patient's history to learn if hypersensitivity exists. (Jour. A. M. A., Aug. 30, 1924, p. 705.)

CASE REPORTS

Members are requested to report interesting and unusual cases for publication in this department. Many cases reported at hospital staff meetings and similar meetings are very instructive and worthy of publication.

**PREGNANCY WITH COMPLICATIONS: CHRONIC APPENDICITIS; LOW ANTERIOR IMPLANTATION OF PLACENTA; DOUBLE FOOTLING BREECH PRESENTATION; FORCEPS ON THE AFTER-COMING HEAD; HIGH POSTERIOR SECOND DEGREE LACERATION WITH SECOND DEGREE LEFT LAT-
ERAL EPISIOTOMY.**

DANIEL H. BESSESEN, M.D.,
Minneapolis

The patient, aged 25, was first seen on October 29, 1923, complaining of scanty menses occurring at irregular periods and constipation with pains in the lower right quadrant. The family and social histories were without importance in this case. She had never been pregnant. On Dec. 11, 1923, the nausea and vomiting were worse, and pains of knife-like character were felt in the lower right quadrant, with distinct tenderness over McBurney's point. On pelvic examination the uterus was found enlarged and the diagnosis of pregnancy with chronic appendicitis was made. Operation was advised, and on December 13, 1923, an adherent appendix was removed. Convalescence was without special note and marked improvement in the patient's general condition was the result. Nothing further occurred of importance until at delivery, on June 1, 1924, when the patient suffered from slightly prolonged first and second stages of labor. Twins were suspected in this case because of the presence in the pelvis of a mass first taken to be a head, but later found to be the placenta. After dilatation was complete, the progress still being slow, the patient was put under complete anesthesia and an effort made to push the mass into the abdomen. The feet of the fetus were grasped, brought down and breech delivery done with the exception of the head. Here such difficulty was encountered in extracting the child, that forceps were applied, a left lateral incision in the perineum made and the head delivered. The release was so sudden that a high posterior second degree laceration of the perineum occurred in addition to the episiotomy. The repair healed per primam.

Appendicitis in pregnancy is of fairly frequent occurrence. It has been observed in general that operations on pregnant women, if done carefully and gently, are not inducive to abortion. It is well to advise according to the individual case.

A low anterior implantation of the placenta is not a common occurrence and when it does occur, it is sometimes of serious import. It frequently leads to early dislodging of the fetal circulation with resulting asphyxiation of the child. When necessary to completely separate the placenta, much speed is required, and often Dührsen incisions into the uterus are of value in securing rapid dilatation.

In applying forceps on the after-coming head, either the assistant may hold the child, or the body of the fetus may be laid on the abdomen of the mother. This facilitates the application.

In the case just cited, the forced required to extract the head, led to the posterior laceration additional to the episiotomy. It occupied all of six minutes from the time of the delivery of the umbilicus to the time of the delivery of the head, so that a white baby was born, resuscitated by hot and cold water baths and by abdominal compression for artificial respiration. Both mother and child recovered nicely.

PROGRESS

Abstracts to be submitted to Section Supervisors.

Members are urged to abstract valuable articles which they run across in their reading and send the abstracts to the physicians in charge of the respective sections. In order to avoid duplication it would be well to communicate with one of the section supervisors before the article is abstracted.

LA SALLE BLDG., MINNEAPOLIS

ON THE MECHANISM OF RESPIRATORY TRACT INFECTION: Arthur L. Blomfield, M.D. (Tubercle [London] 1924, v, 438). In this article, Professor Blomfield, of Johns Hopkins University, sums up a series of studies on the behavior of bacteria in the upper air passages. Tradition has imposed on us the idea that the mouth is a specially favorable situation for bacterial growth, but certain objections can immediately be brought against this idea.

In the first place, the flora on the whole is remarkably constant from day to day and week to week, despite the miscellaneous horde of germs which are constantly introduced with food, fingers, and foreign objects.

Secondly, certain bacteria, such as *Bacillus Coli*, which are especially hardy and not at all capricious in their test tube requirements, are practically never found in the mouth and the chromogens of the air are almost unknown in the respiratory tract.

The series of experiments reported by Dr. Blomfield were undertaken in an attempt to throw light on this problem. Solid masses of bacterial growth from Agar slants were implanted on the tongue, the pharynx, the nasal septum, and the tonsil crypts of volunteers. The subjects were healthy people with clinically normal upper air passages.

The species studied were: *B-Coli*, *Staphylococcus albus*, *B-Influenza*, *B-Friedlander*, and *Streptococcus hemolyticus*. The one hour cultures uniformly yielded great numbers of bacteria, after two hours relatively few were obtained, and within twenty-four hours practically all had disappeared. (In the case of the tonsil crypts, a few organisms occasionally persisted for several days.)

A variety of possibilities suggested themselves by way of explanation of this phenomenon, but it seemed most likely that the flushing of the mouth secretions together with the contractions of the muscular masses of the tongue and pharynx were most important.

There exists in the mouth a highly organized mechanism by which foreign particles and bacteria are eliminated. A similar rapid elimination of bacteria from the nasal passages occurs, but here the sweep of the cilia must be the main factor in the mechanism. In addition to the mechanism described, there are other antagonistic factors. The saliva is probably an unfavorable medium for growth of most pathogenic bacteria. The bacteria normally present may exercise some opposition to the colonization of foreign bacteria. Certain groups of mucus-organism normally thrive in the mucous membranes of the upper air passages, especially hemolytic streptococcus. The dosage of bacteria and their degree of vegetative activity affect the results of implantation. Infection with meningococcus increased to nearly eighty per cent when the spacing between beds in the British Army was in one instance reduced from three to one and a half feet.

Perhaps the most important group of causes which promote bacterial invasion through the upper air passages are injuries of various kinds. Peripheral chilling (cold) is one of these, chemical injury is another, and anesthesia another; but infectious diseases, especially the so-called exanthemata, par excellence let down the bars for infection of the respiratory tract. Measles and influenza are outstanding examples, both producing local erythema.

With these considerations in mind, it may be questioned whether every tubercle bacillus which enters the nose or mouth regardless of source actually invades or even threatens invasion.

ARTHUR T. LAIRD.

PEDIATRICS

ROY N. ANDREWS,
MANKATO CLINIC, MANKATO

ERFAHRUNGEN MIT DUBO: Dr. van Mallinckrodt (Monatschr. f. Kinderh., Bd. 27, Jan., 1923, pp. 438-441). The author thinks that Dubo is especially suited as a complementary feeding in weak infants that refuse large amounts of food. He finds its high calorie value of great importance in bottle-fed babies with impaired digestive function. However, he finds that Dubo is contraindicated when any parenteral infection accompanied by vomiting sets in—due to the danger of exsiccation. Dubo is easily and simply prepared and can be used in the home.

DAVID SIPERSTEIN.

DEHYDRATION: Owen H. Wilson, M.D. (Arch. of Ped., Feb., 1924). In young children the chief source of

water is in milk, which is nearly 90 per cent water, a normal year-old requiring at least 40 ounces of milk daily. In many acute illnesses, food (milk) is discontinued, or, as in the case at hand, is refused, and consequently dehydration is imminent. This is especially true of infectious diarrhea with its excessive fluid drain. This excessive drainage depletes the body fluids, causing the parched mouth, the drawn expression, the sunken eyes, and the dry, parchment-like skin and feeble, thready pulse. Most of the serious complications of infectious diarrhea are traceable to dehydration. When milk is refused or discontinued, the water supply is practically stopped. A sick baby requires as much or more water than a well one. If possible, it may be best to give specified quantities at stated intervals, though this rarely succeeds, and little harm is done by giving fluid at any time the patient will take it. If vomiting continuously, we must resort to intravenous, intraperitoneal, or subcutaneous methods. Giving fluid by the bowel is rarely successful in babies and must not be relied upon. The following method has been used by me for several years. The patient, in a recumbent position, is wrapped in a sheet, the head being steadied by an assistant. A teaspoon is introduced into the mouth, leaving about one-fourth of the bowl protruding beyond the teeth. The curved bowl prevents the teeth or gums from closing, and is far enough into the mouth to prevent the tongue from being pushed up against the roof of the mouth, and obstructing the fluid. Now pour the liquid into the projecting fourth of the bowl with another spoon, or better with a hottle. The fluid fills the pharynx and must be swallowed before breathing is possible. This method would not be advised in a comatose baby, in infants under one month of age, in whooping-cough, or when there is laryngeal paralysis. It is a most excellent way to give castor oil to a refractory patient. Remember in treating a sick baby he must have his daily quart.

R. N. ANDREWS.

COLIC IN BREAST-FED INFANTS AS A RESULT OF SENSITIZATION TO FOODS IN THE MOTHER'S DIETARY: W. Ray Shannon (*Arch. of Ped.*, December, 1921). For some time it has been held that the diet of the mother could not affect a breast-fed infant. Shannon, in a previous paper, has shown, however, that food taken by the mother may appear in the breast milk and give rise to ana-phylactic reactions in the infants. These reactions may affect the skin, respiratory or the gastro-intestinal system.

He cites six cases of colic in infants due to such reactions. In each case skin tests were done on the infant with foods from the mother's dietary and positive results obtained. The removal of the offending foods caused the disappearance of the colic. In each of these cases egg was one of the foods which caused the trouble; it is noted that egg protein has been responsible for some of the manifestations of exudative diathesis in artificially-fed children.

It is concluded that the food allergy demonstrated in these cases is a reasonable basis for explanation of the old statement, "that all breast milk is not the best food for every baby."

A. M. SNELL.

ENZEPHALOGRAPHIE IM SAUGLINGSALTER: Knoepfelmacher (*Jahrbuch f. Kinderheilkunde*, March 5, 1924, pp. 181-187). Knoepfelmacher recommends encephalography as a valuable diagnostic procedure in infancy. He removes small amounts of cerebrospinal fluid through a ventricular puncture and injects an equal amount of air into the ventricle. He thinks that this technique enables one to make a definite diagnosis of hydrocephalus. He also considers it an aid in the diagnosis and localization of brain abscesses.

DAVID SIPERSTEIN.

MENINGOCOCCUS MENINGITIS: (*Archivos Españoles de Pediatría*, Madrid, Nov., 1923). (*Arch. of Ped.*, May, 1924). The vascular communication with the ear in very young children explains the frequency of meningitis in connection with otitis. The otitis is often metastasis of meningococcemia. With headache, vomiting and fever, followed by signs indicating muscular hypertonicity (Kernig, etc.) lumbar puncture is imperative, and serotherapy should be continued with large doses until the meningococci have definitely disappeared. The spinal fluid may show 3 gm. of albumin and 54 cells per cubic millimeter, as in one convalescent recently, but this alone does not call for continuation of the antiserum. Parallel lumbar puncture and injection of saline in some healthy children showed up to 2 gm. albumin and 40 or 50 cells. One child died the eighty-fourth day, and meningococci were found in the fluid. Serotherapy had been discontinued a month before. González Alvarez reiterates the warning that the throat of all contacts must be disinfected, and serotherapy must be pushed with larger doses than those generally used.

R. N. ANDREWS.

ACIDOSIS AND TOXIC SYMPTOMS OF SEVERE DIARRHEA OF INFANCY (*The Lancet*, London, Oct. 29, 1921; *Arch. of Ped.*, February, 1924). In certain of the diarrheas of infancy, symptoms of intoxication, the chief of which is increased pulmonary ventilation, are accompanied by a reduction in the reserve of bicarbonate in the blood plasma. The hypernea and the alkali reserve vary inversely. The reserve can be increased to normal by the administration of sodium bicarbonate. Hypernea is thus controlled and the general toxic symptoms are alleviated, but the ultimate outcome, in the diarrheal cases at any rate, is little influenced. Necropsy throws no light on the questions of the site or extent of the damage done. The usual lesions of gastroenteritis are the only ones found. Depletion of the alkali reserve is not a cause of the diseased condition, but is caused by it and is essentially, like an elevation of temperature or an acceleration of the heart rate, a variation in a physiological constant, an indication of deranged function. And just as fever and tachycardia demand certain therapeutic measures for their own sake, so acidosis indicates the administration of alkali and fluid and the stimulation of excretion. When the acid produced and the cause of its production are known more specific therapy may be available. These observations have confirmed the work of previous investigators.

R. N. ANDREWS.

ROENTGENOLOGY

SUPERVISORS:

LEO G. RICLER,

MPLS. GEN'L HOSPITAL, MINNEAPOLIS

A. U. DESJARDINS,

MAYO CLINIC, ROCHESTER

Of the eight cases reported there were four carcinomata, one epithelioma, one endothelioma, one chondrosarcoma and one xanthoma.
LEO G. RICLER.

RONTGENBESTRAHLUNG NACH RADIKALOPERATION DES BRUSTDRUSENKREBSSES: W. F. Wassink and C. Ph. Wassink von Raamsdonk (*Acta Radiologica*, v. 3, p. 113, June, 1924). Three groups of cases of mammary carcinoma, in which roentgenotherapy was employed were considered.

The first, consisting of 78 cases, were operated in their clinic and given heavy doses of radiation within two weeks of the operation.

The second, consisting of 30 cases, were operated elsewhere and were given radiation some time after operation.

The third, consisting of 92 cases, were operated elsewhere, without radiation after operation, and came to them for radiation after recurrence.

In the first two groups very few recurrences were noted while in the third they were frequent. Radiation had very little effect in the recurrent cases. The results in the cases radiated at once after operation indicate that postoperative roentgenotherapy is of considerable value. They could find no case, in which there was no carcinomatous infiltration of the skin, which was harmed by the radiation.

LEO G. RICLER.

OSSEOUS DEVELOPMENT IN ENDOCRINE DISORDERS: Engelbach and McMahon (*Radiology*, v. 2, p. 378, June, 1924). This paper, published simultaneously in "Endocrinology," is an attempt to present the changes in time of appearance and time of union of the nuclei and epiphyses of the bones. Numerous charts are presented, giving, in tabulation form, the usual accepted normal standards, the authors' normal standards, and their method of examination. Their normal standards differ from those of the anatomists, the pediatricians, and the roentgenologists. They believe this is due to a stricter ruling out of slight endocrine disturbances from their group of normals.

The material presented is too extensive to be properly summarized. They believe roentgen examination of the bones may prove to be more valuable in the diagnosis of endocrine disorders than any other form of examination. Their findings in all the bones in hypothyroidism, hypogonadism and eunuchoidism, anterior lobe pituitary insufficiency, pluriglandular syndrome, pubertas, præcox, and thymolymphatism are given with profuse illustrations.

LEO G. RICLER.

THE DIAGNOSIS OF PRIMARY INTRATHORACIC NEOPLASMS: (Am. Jour. Roent., May, 1924). Eight cases of primary intrathoracic neoplasms in which the diagnosis was correctly made during life are reported. In four of these the roentgen examination was the chief diagnostic measure and the authors believe it is the most important means of diagnosis. They advocate more routine roentgen examinations rather, than as now used, for confirmatory purposes. They emphasize the early use of stereoscopic plates before pleural effusion or lung collapse has appeared as the findings may be obscured by the latter.

A brief discussion of the pathology, symptoms and physical signs is given.

Roentgenologically the cases must be distinguished first from inflammatory processes, second from benign tumors. Tuberculous lobar pneumonia must be distinguished from the massive lobar type of carcinoma and miliary tuberculosis from miliary carcinosis.

Malignant tumors differ from benign in that they are rapidly growing, have an indistinct border, radiate, are multiple, show metastases to ribs and vertebrae and have pleural effusions frequently. Another secondary manifestation of importance is the collapse or complete filling of a lobe due to obstruction of a bronchus by tumor mass.

They advise paracentesis in cases with pleural effusion followed immediately by roentgen examination as the fluid returns very rapidly in malignant cases. They have derived no diagnostic benefit from pneumothorax. Hodgkin's and lymphosarcomata may be distinguished by their rapid response to mild doses of x-rays.

RENAL FLUOROSCOPY AT THE OPERATING TABLE: Braasch and Carman (*Radiology*, April, 1924). In all cases of operation for kidney stone, where nephrectomy is not contemplated, fluoroscopy of the delivered kidney at the operating table is of value for three reasons: (1) Stones previously unrecognized can be detected; (2) stones can be accurately localized; (3) the removal of all stones can be assured. In many cases pre-operative roentgenograms do not demonstrate all the stones or indicate two stones where one branched one is present. Frequently, it is difficult to locate the stones without needling and incising the cortex, which is very injurious to the kidney. It is often impossible to determine whether all stones or pieces of stones have been removed, if palpation alone is used. Without using this method about 10 per cent of post-operative roentgenograms showed stones which had not been removed. With this method the percentage was reduced to 1.2 per cent.

The important facts in technique are thorough dilatation of the eyes, thorough darkening of the room, and as complete delivery of the kidney through the wound as possible. A short pedicle or fixed kidney may interfere materially with the success of the procedure. The roentgenologist guides the surgeon's forceps to the stone. The authors prefer fluoroscopy to roentgenograms of the delivered kidney, although the latter are of advantage when the kidney cannot be raised above the abdominal wall. They conclude that conservative operation for kidney stone cannot be done with complete success without the aid of fluoroscopy at the operating table.

LEO G. RICLER.

BOOK REVIEWS

GOITER: NON-SURGICAL TYPES AND TREATMENT.

Israel Bram, M.D., Instructor in Clinical Medicine, Jefferson Medical College. 479 pages. Illustrated. New York: The MacMillan Co., 1924.

This monograph on goiter gives a very complete review of the anatomy and physiology of the thyroid gland, with a classification of goiter arranged according to: (1) pathology, (2) clinical signs, (3) therapeutics. The classification under Therapeutics is as follows:

A. Surgical Goiter. Adenomatous, cystic and all other thyroid enlargements not classified under non-surgical goiter.

B. Non-surgical Goiter.

1. Parenchymatous hypertrophy.
2. Colloid goiter.
3. Puberty hyperplasia.
4. Hyperplasia of exophthalmic goiter (Graves disease).

About 100 pages are devoted to the diagnosis, prevention and treatment of simple goiter and puberty hyperplasia and contain nothing that has not been standard for a long time.

The balance of the book, some 350 pages, is devoted to the etiology, symptomatology, diagnosis (with a very good review of the various diagnostic tests), prognosis and the author's views as to the treatment and management of all cases of exophthalmic goiter. A considerable number of case histories are presented in support of the author's conclusion that "Surgery, unable to remove the cause of the affection, is a fallacious procedure. Non-surgical measures, the rational therapeutics of exophthalmic goiter, overcoming the dysfunction of the various structures and organs of the body and restoring the interglandular and neuroendocrine relationship, break up the various physical and mental vicious circles with consequent restoration to permanent health.

"All things being equal, the prognosis of Graves' disease under non-operative treatment is excellent; recovery is complete and permanent, and the patient, taught how to 'carry on' and imbued with a healthy philosophy of life, becomes and remains stronger in body and mind than ever before."

The book is profusely illustrated with photographs and charts and has a voluminous bibliography.

HARRY OERTING, M.D.

ASSISTANT WANTED as soon as possible, to do general medical work in clinic. New modern hospital and well-equipped offices. Will pay \$200.00 per month and all expenses pertaining to practice. Address Kittson County Clinic, Hallock, Minnesota.

EXCELLENT OPENING in southwestern Minneosta for cost of drugs and office furniture. Good territory. Only physician desires to locate on coast. Good roads; four-year high school; mixed community. Address C-4, care MINNESOTA MEDICINE.

MINNEAPOLIS OFFICE SPACE TO SUBLET — Very desirable office space at 323 La Salle Bldg., Minneapolis, to be sublet by Drs. Willson, Cabot and Wohlrahe. For information call at office or telephone Main 3220.

MEDICAL DOCTOR WANTED at once in city of 4,000 population. Community hospital, good territory. For particulars write Mlinar Drug Store, Hutchinson, Minn.

GRADUATE NURSE wants position in doctor's office. Will furnish references. Address Box 44, Sauk Center, Minn.

NOTES BY THE WAY—WISE AND OTHERWISE*

C. EUGENE RIGGS, M.D.

Prof. Emeritus, Nervous and Mental Diseases,
Medical Department, University of Minnesota
St. Paul

From Hippocrates of Cos to his English successor, Sydenham, is a long cry—a little over 2,000 years; and since the birth of the latter—three hundred years—more advance has been made in medicine than in all the preceding years of human history. So great was the admiration of Boerhaave, the great physician of Leyden, that he never mentioned Sydenham's name without lifting his hat. A writer¹ of an historical retrospect of surgery in 1824 very confidently asserted "that surgery, operative surgery, has now clearly achieved all that can be expected from it." Yet, within the ken of my professional experience, medical science has made its most notable achievements, greater than in all previous times. Hippocrates relied upon the *vis medicatrix natura*; he used but few drugs, and these sparingly. It was a maxim of his "that natural powers are the healers of disease." Galen taught that disease is something to be expelled from the body, a *materia peccans*, that must be eliminated by purgation, blood letting, diaphoresis, etc. "Galen² coerced nature; Hippocrates supported her." A happy medium between these two really complementary conceptions is the modern concept of the therapeutics of today. The successes and the failures of our historic past but stimulate to worthy endeavor, and warn against speculative theories and imaginary cures. "Study out the secrets of nature by way of experiment," says Harvey.³ This is the only safe guide. An instance of false theorizing and fanciful speculative reasoning, leading to absurd therapy with highly imaginative reports of improvement and cure,

illustrating the credulity of our profession at times, is seen in the suspension treatment for nervous diseases so popular forty years ago. In a paper⁴ at that time, based on many suspensions of tabetics made for me by the late Dr. Gillette, I said that suspension was purely empirical, without a rationale, and rested on nothing more substantial than theory. In none of our cases was there definite improvement. This procedure was used in a variety of organic nervous conditions such as amyotrophic lateral sclerosis, disseminated sclerosis, transverse myelitis, paralysis agitans, etc. Suspension was first suggested by Motchoutkowski and popularized by Charcot. The most encouraging reports came from the French and American experimenters. The English and Germans lagged, both in enthusiasm and results. In fact, Mendel and Eulenburg called attention to the fact that their patients improved more under electro-therapy than under suspension, and stated that they were glad to return to its use. The later discovery of the spirocheta pallida revealed the utter absurdity of this nerve-stretching epidemic and showed that nothing more unscientific, chimerical or ridiculous ever swept over the medical profession.

Thirty-one years ago⁵ I called attention to the value of voltaic alternatives in certain forms of atrophy of the optic nerve. Dr. Webster Fox, of Philadelphia, who had also used this form of treatment, said to me that he hesitated to publish his findings; they were so surprising that he felt that the profession would receive them incredulously. I recall one case in which the atrophy was arrested, and a clinical recovery ensued. This patient was under the constant observation of the oculist, Dr. B. F. Graham of Minneapolis, who referred him to me. Unlike suspension, this form of therapy rests on a physiological basis. The reversal of polarity in the constant current has a much more marked nutritional influence than simple closure of the circuit, while rapid reversals greatly intensify its stimulating effects. In order that this might occur with evenness and great frequency, I had an auto-

*Read before the St. Louis County Medical Society, Duluth, June 19th, 1924.

matic commutator designed that admirably accomplished this purpose. Notwithstanding the greater knowledge that has come to us with the passing years, voltaic alternatives, I believe, would prove a useful adjuvant in the treatment of the toxic forms of optic atrophy. Therapy has its fashions. The more dramatic their form, the greater the popular appeal. Static electricity as a mode of treatment is now obsolete. Even the galvanic and faradic currents, aside from diagnostic purposes, have fallen into the discard, much, I believe, to the disadvantage of the patient. Now the d'Arsonval, or high frequency current, occupies the limelight in electro-therapeutics. The most approved form of its application is that known as diathermy. It is said to warm the body tissues. The resistance of these tissues, like that of a wire, generates heat; the greater the resistance, as in passing through a bone, the greater the heat. The value of hot applications is well known, but their effect is confined to the surface, while in diathermy it is claimed that the portion of the body included between the electrodes can be raised to any desired degree of heat, and as heat is fatal to many pathogenic bacteria, it is predicted that this treatment may have a curative influence on diseased parts deeply situated. When the alternations exceed fifteen thousand a second, there is no pain; only an agreeable sensation of warmth. A moderate amperage raises momentarily the body temperature, slightly accelerates the pulse, dilates the blood vessels, and lowers the blood pressure. Its range of therapeutic usefulness includes such conditions as high blood pressure, the functional nervous disorders, pneumonia, rheumatoid arthritis, neuritis, arthritis, angina pectoris, as well as other forms of cardiac disease, neuralgias, and the persistent and intractable pain which occasionally follows herpes zoster. The therapeutic potentialities of diathermia are at present a matter of conjecture; its curative powers are yet to be determined.

The first six years of my professional life in St. Paul were spent in general practice. It was during this period that the city suffered from an epidemic of malignant diphtheria, and occurring before the days of the bacteriological laboratory, there was no possible way of distinguishing between it and tonsillitis, which at the time was widely prevalent. Dr. J. H. Murphy, a well-known St. Paul physician, big of body and humorous of speech, in commenting on the difficulties of diag-

nosis, remarked that the way he made a diagnosis was to wait and see whether the patient died or recovered; if death occurred, it was diphtheria; if he recovered, it was tonsillitis. Dr. E. J. Abbott at this time deservedly distinguished himself by his great skill and celerity in intubation in laryngeal diphtheria. Practicing medicine today, one cannot fully realize how handicapped we were without the knowledge of antitoxin or the Schick test and von Behring's toxin-antitoxin. Before antitoxin the mortality ranged from 45 to 50 per cent annually; after its use it fell to 10 per cent. From 80 to 85 per cent of the deaths occurred⁶ among children under six years of age. The recent illness of some forty school children at Concord and Bridgewater, Massachusetts, following the employment of the latter (toxin-antitoxin) is worthy of mention. The serum had been subject to prolonged cold, and investigation revealed that freezing serum caused a partial dissociation of the antitoxin from the toxin, giving rise to a toxicity which originally was absent; moderate freezing was apparently harmless; after severe freezing of eighteen hours it should never be used (Kelley). Antitoxin itself, under similar conditions, may also lose its potency. Am I too optimistic when I predict that with the universal employment of the Schick reaction and immunization by von Behring's vaccine (in only 5 per cent of the cases is it unsuccessful and has to be repeated) the conquest of this scourge will be an accomplished fact?

It is an interesting coincidence that an immunity test analogous to that of the Schick reaction in diphtheria has been found for scarlet fever. The G. F. and the G. H. Dick reaction⁷ is due to an intracutaneous injection of a soluble toxic substance obtained from the culture of certain hemolytic streptococci from scarlet fever patients, which causes a local flushing of the skin. The reaction occurs in patients who have not had scarlet fever and in the early stage of the disease. Branch and Edwards,⁸ after using the specific streptococcus filtrate of the Dicks, state that the Dick reaction has seemingly "a specific relationship to immunity to scarlet fever." Dochez⁹ reports an antiscarlatinal serum which not only blanches the skin locally in scarlet fever, but materially relieves the symptoms when used therapeutically. The observations of Blake, Trask and Lynch¹⁰ in a preliminary report confirm the findings of Dochez with regard to his scarlatinal antistreptococcus serum, both as to the

rash extinction test and its therapeutic value. Zinger has used successfully, both as a prophylactic and a therapeutic agent, the serum of convalescent and recovered scarlet fever patients. The laboratory we hope, in the near future, will find not only a curative serum, but a protective vaccination as well. A similar immunity reaction in measles, which has a death rate in children third among the acute contagious diseases, is greatly to be desired. Especially is this disease to be dreaded under the fifth year of age. The death rate in New York City in 1922 for children under one to five years of age was 93.4 per cent. Later in childhood the mortality is markedly reduced. In adults it at times assumes a serious virulence. Fortunately, convalescent serum, which fails to protect in less than three per cent of the cases, gives a limited immunity, which, according to Drs. Weaver and Crooks,¹¹ is about two months. Lasting immunization has yet to be achieved. Notable changes have occurred since those days of general practice. Phlebotomy was then a routine procedure. It was an approved treatment of lues to use an escharotic on the initial lesion and to defer other medication until after the appearance of the secondary symptoms. In my boyhood home in northwestern Ohio, where malaria was prevalent, an ounce bottle of quinine was kept on the table by many, and was partaken of with the same regularity as the meals. Now, malaria, typhoid fever, and yellow fever are practically eliminated, and soon will possess merely an academic interest. That once terrible scourge, epidemic cerebro-spinal meningitis, is a Prometheus bound.

These are only a few instances of what medicine and sanitary science have accomplished. Equally interesting to me is the disappearance of that anemia peculiar to adolescent girls, known as chlorosis, an affection in my observation of not infrequent occurrence, and by no means confined to factory girls and domestics, as certain writers would have us believe, but oftentimes seen or observed where food, fresh air and environmental conditions were far from unfavorable.* Its etiology

is obscure, but Campbell believes that "the frequency of the low specific gravity of the blood in apparently healthy women at the age of puberty suggests strongly that chlorosis is an exaggeration of a physiological change occurring in all girls rather than a disease *sui generis*. There are many other changes, structural and functional, which take place at this time, and it is known that they depend on the internal secretion of the ovary. It is difficult to avoid the conclusion that the changes in the blood also depend on changes in the ovary and that it should be considered with diseases of the ductless glands." Fifteen years ago Dr. Richard Cabot wrote, "The disease seems to be dying out." The study¹² of the Guy Hospital cases for the past thirty years is an interesting and illuminating contribution. From this it would appear that chlorosis has steadily declined since 1903. It has been many years since I have seen a case. This caused much conjecture on my part. It did not seem to me that our increased knowledge of disease or our refinements in diagnosis were sufficient to account for this. The passing of chlorosis within about a generation, without any apparent cause, medical or otherwise, is as puzzling as it is notable. This is, however, an outstanding fact, and clearly evident, and shortly this disease will possess only an antiquarian interest.

I wonder how many of you have observed the soporific action of calomel or blue mass in so-called biliousness, which is really an auto-toxemia. Mercury has been greatly abused by careless and indiscriminate administration. The inevitable reaction against it is both unjust and unreasonable and is greatly to be deprecated. For the relief of the insomnia, restlessness, headache, chilling, fever, rapid pulse, vomiting, furred tongue, serous diarrhea, mental sluggishness, etc., incident to these autotoxic attacks, calomel or blue mass affords prompt relief, and gives the patient a night of refreshing sleep. Murchison believes that mercury possesses a double action, that whether or not there is an increased secretion of bile there is more bile passed when mercury is given and an eliminating action is set up, and less of the bile constituents are absorbed from the intestine. I have noticed for years this marked soporific effect. Recently Dr. Tyson¹³ has also called attention to this unrecognized action of mercury.

It is worthy of note that 7 per cent of all medical cases are neurological and that three-fourths of all

*Professor Deneke in The Deutsche Medizinische Wochenschrift (p. 902, July 4, 1924) reports a marked decrease in chlorosis. In 1901 out of 12,000 admissions to the St. George Hospital, Hamburg, there were 201 cases of chlorosis, while in 1923 in 20,000 admissions there were only 3 cases of this disease. It was of frequent occurrence in this hospital up to 1904; the peak having been reached in 1901, with an incidence of 16.2 per thousand. After 1904 there was a rapid decline until the minimum of 0.15 per thousand was observed, in 1923. A striking decline in chlorosis has also been reported in France.

the neurological cases sustain a relation to the major problems in internal medicine (Hyslop). Our present conception of neuropsychiatry is at wide variance with that of even a decade ago. The so-called degenerative diseases of the central nervous system, such as disseminated sclerosis, progressive muscular atrophy, paralysis agitans, etc., are not due to abiotrophy, as was at one time believed, but are the clinical manifestations arising from a chronic infection, probably of a microbic nature. The acute great infections of the central nervous system are epidemic cerebro-spinal meningitis, poliomyelitis, and encephalitis lethargica. The etiology of the two former is known; that of the latter is yet to be discovered. The term functional nervous disease is a misnomer; it is inaccurate and unscientific—a medical myth. All disease manifests a perversion of function. The clinical syndromes of which they are the expression arise from a variety of causes, notably infection, faulty metabolism, ductless gland disorders, anaphylaxis, and focal infections. The psychoneuroses, hysteria, neurasthenia, multiple personality and psychasthenia are not diseases, only clinical syndromes, and are manifestations of disorders of personality resulting from exhausting illnesses, stress, and strain incident to a failure of adaptation to life and environment. "The whole of life," says Herbert Spencer, "is an adjustment—a continuous adjustment of inner to outer relations."

Kraepelin¹⁴ formulated his epoch-making views regarding insanity twenty-eight years ago, differentiating at the time, on the basis of their symptoms, between dementia precox† and manic-depressive insanity. He regarded the prognosis in the former as bad, in the latter as good. Later writers, notably Bleuler, have discounted his pessimistic conception of dementia precox, and have in addition clarified our knowledge of this great subject. Bleuler designated all the adolescent mental disorders, with the exception of manic-depressive insanity, as schizophrenia. In the schizophrenic reaction are included dementia precox, the paranoid states, hallucinosis, and the abnormalities of personality, all of which spring from an underlying basic degenerative taint. Necessarily, the widely varying factors entering into the schizo-

phrenic reaction present a greatly differing prognosis from that of a classical precox. A dramatic illustration of the part heredity plays in the evolution of insanity is described by Bonhoeffer,¹⁵ who had charge of 10,000 Serbian prisoners during the Great War. Notwithstanding that they were subjected to every form of stress from disease, famine and hardship, there developed in these soldiers only five cases of insanity. It is far from my purpose to discuss the adolescent or any other form of psychosis, but rather to call attention to the great importance of prognosis in insanity, and also to protest against our making as in the past the prognosis depend upon the clinical group in which they may happen to be classified. It is the usual thing after the diagnosis of a dementia precox to shrug the shoulders and say, "Oh, it is a precox—the prognosis is hopeless and therapy futile." Almost universally, medical men believe that after recovery from manic-depressive and schizophrenic psychoses, recurrence and mental deterioration are inevitable. As Rosanoff and Bergman have shown, this is not necessarily so. In their report of eight cases of these psychoses (seven women and one man) in which they followed each individual after-history for thirty or forty years, there was no second attack. The percentage of permanent recoveries, if carefully searched for, would be much greater than we have suspected. This spirit of medical hopelessness is not justified by the facts, either as regards prognosis or hereditary taint. The pessimism of Kraepelin concerning the former, experience fails to confirm, while the studies of Canavon have shown that the latter is not as dominant as commonly believed. An investigation of 381 offspring of dementia precox patients revealed astonishingly few mental peculiarities, 77.4 per cent being normal. It must be noted, however, that in some children the precox age had not been reached.

This archaic conception of the psychoses represents the past, but it is not the attitude of the neuropsychiatrist of today regarding these adolescent mental states. McCarthy believes that a large proportion of adolescent mental disorders get well, and the Trenton workers report from 60 to 80 per cent of recoveries. Prognosis no longer should be governed by nosological grouping. Adolph Myer has pointed out that the old views have "largely failed to bring out the most vital factors," and that the possibilities of the future depend

†At one time the diagnosis of dementia precox was made in almost fifty per cent of the admissions to mental hospitals. Now this occurs in about fifteen per cent of the cases. (Ruggles).

entirely upon the reaction type of the individual patient. Prognosis then lies not so much in clinical types as in the manner of reaction to life conditions and environment. Constitutional tendencies may cloud one's future, but faulty adaptation is by far the greater menace. The basic factor in faulty adaptation is the degenerative taint. The ability to adjust is the index of this inadequacy and a reliable guide in prognosis. In addition to the psychic factor the potentialities of endocrine disturbance and focal infection should not be overlooked. To the general practitioner, this matter of prognosis in insanity is a matter of paramount importance since mental affections are of such common occurrence. In Massachusetts, according to Dr. Vernon Briggs,¹⁶ one out of every ten of the adult population at one time or another during his life requires care in a hospital for mental and nervous disorders. In the acute infections, delirium, especially if there is a high temperature, is of common occurrence. Pneumonia is an exception, for in this disease it is uncommon. When present it may be apparently the only symptom, the actual trouble being revealed only by an examination of the chest. Tyson has reported three cases of acute mania following the crisis. In this affection, the acuteness of the excitement, or its duration, bore no relation to the amount of lung invasion. The pneumonia was of asthenic type. The patients were neuropathic, and were under 40 years of age. The manic state was evidently of a toxic nature and the recovery was rapid, yet it must be kept in mind that, aside from toxic insanity, acute infections can give rise to typical syndromes of manic-depressive and dementia precox types. These psychoses in no way differ from the usual manifestations of these affections, the prognosis being favorable or unfavorable, just in proportion to the way in which the patient had been able to adjust himself to the life requirements prior to the inception of his illness.

I have never been able to understand why trauma* of the central nervous system should receive attention so out of proportion to that accorded other forms of bodily injury. The probable reason is the commercial significance of the nervous phenomena supposedly incident to it. This it is that has stimulated the fervid imagination of the ambulance chaser and the cupidity of the liti-

gant, while the monetary cost arising from this assumption of a greater gravity, baseless aside from certain, not frequent, exceptions, has been staggering. This is the lesser evil, the greater by far being the decay of moral fiber and the loss of personal initiative developed in the social order. Wilson¹⁷ pertinently asks whether the influence of trauma has not been greatly over-rated, and whether there is not a true cause for tumors and degenerations as there is for infections to which the nervous system is liable; also, whether etiologically there can be any real difference between nervous disease and other affections of the somatic systems. The answer to this question is found in the results of recent research which indicate that both the acute and so-called progressive degenerative forms of nervous disease arise from an infective process. A patient suffering from scarlet fever or diphtheria may have experienced a trauma, but no one today would attribute the symptoms to this cause, and it is equally unscientific and fallacious to do so in nervous states which in like manner spring from an infectious source. The degenerative nervous diseases, whether they are manifestations of abiotrophy or infection, pursue a typical course. It makes no difference whether their etiology is undetermined or supposedly due to trauma, the latter being active in only a relatively small proportion of the total number of cases. The wider knowledge of today enables us better to appreciate the true scope and real significance of trauma, the result of which, according to Orbison, lies largely in the money sense.

Trauma can only be regarded as a contributory factor. Can it stimulate a pathogenic activity in a latent or innocuous micro-organism, and why is this pathogenity confined so exclusively to nervous disease? As to its lighting up of a process in abeyance, I think this most improbable. As to a tabes, a paresis, or a multiple sclerosis being due to trauma, this, with our present knowledge, we know to be an absurdity. It is more probably the flaming up of a latent infection which happens to occur coincident with the injury. The old idea of a lessened bodily resistance accounting for the setting up of the morbid process is archaic and unscientific. An illustration of a latent condition springing suddenly to the surface is furnished by Charcot. He states that during the siege of Paris in 1870, a French woman saw her husband's horse return riderless from a sortie. Immediately she

*Fracture or punctured wounds of the skull, fracture-dislocation of the spine or intracranial lesion due to grave trauma do not enter into this discussion.

developed a typical paralysis agitans, which was attributed to fright. The recent studies in lethargic encephalitis have indicated to us quite definitely the pathology of Parkinson's disease, making such an explanation impossible. Fright also used to be regarded as one of the cardinal causes of Sydenham's chorea, which we now know to be due to an encephalitis. Wilson, however, takes a more liberal attitude toward trauma as a contributory factor than my observation justifies. Unless symptoms of paresis or tabes develop within 48 hours after injury, he asserts that there can be no causal relation between accident and symptoms. In true nervous trauma there occurs an immediate manifestation of symptoms (Wilson). I am not in sympathy with the present tendency to confine the effects of trauma to simply functional disturbances. Its assigned rôle, however, has been greatly exaggerated. There has been much acrimonious discussion regarding delayed traumatic apoplexy. In the cable car accident in St. Paul many years ago there was a man about 50 years of age. His health prior to his injury was excellent. Immediately afterwards he developed insomnia, associated with headache, and a distressing neuralgia. About three months after his accident he had an apoplectic seizure. Suit was brought against the street car company. The trial was a battle royal, and bitterly contested. One of the largest verdicts ever given in a Ramsey County Court was awarded him. In those days cerebral hyperemia with a recognized syndrome was accorded a place in nervous nosology. This was supposed to have been caused by the accident and was given as an explanation of his symptoms, and was believed to be responsible for the cerebral hemorrhage. At that time our knowledge of cerebral arterial sclerosis was quite primitive and the significance of blood pressure was yet to be revealed. Schaller reports the case of a man who sustained a head trauma. After an interval he developed typical hysterical symptoms. Subsequently he died from an intercurrent disease. Autopsy revealed a hemorrhage in one frontal lobe. In order to establish a causal relation between trauma and nervous phenomena the symptoms must be continuous from the moment of injury. Can a blow on the head cause a brain tumor? Mendel cites six cases, four personal, two from other sources, in which the question of a possible relation between the head injury and the neoplasm arose (Wilson). My own obser-

vations have never suggested to me such a relationship. The countless number of head injuries during the late war would, had it existed, have demonstrated, according to Wilson, such a relationship. He states he has never seen such an instance and that this idea that a head injury can give rise to a tumor is wholly unjustified. While I have never observed any relation between trauma and cerebral tumor, yet between it and a brain cyst the probability of such a relationship the following case would seem to suggest. Many years ago, Dr. Charles A. Wheaton referred a case of epilepsy in a young man to me, apparently traumatic in character. While cutting ice the patient was struck on the head by a crowbar. The immediate symptoms were unimportant. Some six months later he had an epileptiform attack of the grand mal type. After this they occurred with distressing regularity. There were no Jacksonian seizures; the symptoms were characteristically those of an essential epilepsy. The neurological examination was negative, and, since there was no evidence of a focal lesion, I suggested that he be put on the routine treatment for this disease. A year later I again examined him, with negative findings. As treatment failed to control the attacks, I advised exploration over site of injury. Dr. Rogers operated and found a cyst. Recently, Reynolds has reported the case of a girl who was struck on the top of the head by the falling of a heavy screen. The case had been previously diagnosed as an hysteria, in spite of a bulging eyeball and haziness of the nasal margins of the discs. There was in addition some disturbance of sensibility. Operation revealed a well-marked arachnoid cyst across the top of the head. There were no convulsive attacks as in my patient. These, it would appear, depend less on the brain injury than upon inherent nervous instability. "The later falls and injuries," says Clark,¹⁸ "when not the result of unobserved seizures, are but the provoking agents to a convulsive state that seems to have been long hanging fire." Of 241 cases of convulsive attacks due to various causes observed by Ostheimer¹⁹ in ex-service men, 17 per cent were latent epilepsies brought to the surface by war conditions. War was merely a provocative influence, the determining cause being neuropathic tendency. Turner reports that in 18,000 cases of gunshot wounds, or other injuries to the head occurring in warfare, less than 5 per cent developed epilepsy. Holmes and Sar-

gent state that out of 610 cases of gunshot wounds of the head, 6 per cent developed epilepsy. Wilson, in quoting these statistics, says that this percentage is much less than one might expect if trauma played the part usually attributed to it. He commends the opinion of Turner that something more than local tissue alterations are requisite for the production of traumatic epilepsy, and that the determining factor is an inherited or inborn constitutional predisposition to nervous instability and epilepsy. Epilepsy is a syndrome, not a disease. Essential epilepsy is a medical abstraction, not a concrete fact. It is a gratuitous assumption, a theory to explain undetermined etiological factors, probably of many kinds. The distinctive fact to bear in mind is that in epilepsy we are not dealing with a disease but with a clinical ensemble. We have been accustomed to speak of the convulsions in epilepsy as being due to a disruptive cortical discharge, but the experimental work of Pollock²⁰ would seem to indicate that the ganglion cells of both the brain and brain stem possess epileptogenous qualities.

One of the most difficult problems of all medicine is that of the relation of trauma to functional nervous disorders. The perplexity of the medical mind regarding such nervous manifestations as hysteria, neurasthenia, traumatic neurasthenia, psychasthenia, which, as Wilson aptly remarks, possess neither etiologic, symptomatologic nor terminologic agreement, an inchoate group, is as great as it was thirty years ago, when it was dominated by the teaching of Erichsen and Page, which to us today seems very primitive. It is slow to recognize that we are dealing with arbitrary clinical syndromes that have in fact no existence, not with actual types of nervous disease. These syndromes differ from one another only in degree and depend entirely upon inherent nervous instability and environmental stress. The whole gamut of nervous phenomena develops in this way, and the attempt to pigeon-hole it into nervous syndromes in light of the new psychology is most absurd. Experimentally, it has been demonstrated that there is such a thing as spinal concussion. It presents distinctive symptoms such as the lessening or loss of power in the legs, impairment in the organic reflexes; the plantar reflexes may be abolished temporarily or there may occur flexion or extension; the deep reflexes also may be diminished or lost, while conduction of sensation is unimpaired. This may

occur, according to Newton, after motor conduction is lost (Wilson). In the slight cases of spinal concussion, it is impossible to distinguish between the symptoms with an organic base and those purely of a functional character. This is a matter of no importance, because in both instances the prognosis is good. After the symptoms of genuine concussion have all disappeared the nervous phenomena may persist indefinitely. This applies equally to all cases associated with trauma where the element of concussion does not enter. This persistence of symptoms is due to the morbidities of the accident complex in the subconscious reflecting themselves through all the activities of the patient. The genuine concussion syndrome is of infrequent occurrence; the great majority of the cases belong to the purely functional class. In these functional states a physical injury may give rise to less disturbance than a psychical trauma. Some of the most marked alterations of personality are observed in the latter. In dealing with nervous phenomena associated with trauma, two things are to be considered: first, the mental factors basic in the evolution of these nervous disorders; second, the psychobiological reaction peculiar to each individual patient. Functional conditions associated with trauma should be termed disorders of personality. The attempt to classify them as in the past as hysterias, etc., is unscientific, confusing and useless. Schaller tells us that at the time of the earthquake in San Francisco, no true nervous disorders (so-called neurasthenia, hysteria, etc.) developed immediately following it, but some time afterward, in the period of meditation and of suggestion, there were many. This incubation period is equally present in all the manifestations of nervous trauma. It is at this time that a psychic evolution takes place on the part of the patient. There enter into this certain dominant factors, such as adequate compensation, suggestions of friends, and the feeling described by Collier that the accident is a valid excuse for a living at the expense of the former employer. Years of observation have convinced me that in the majority of these "Fight for Compensation" cases, as the Germans call them, there is a subconscious fear, due partly to ignorance, largely to misrepresentation of the evil consequences of trauma, commonly associated with cupidity and moral obliquity. These are the genetic influences, the dominant mental factors in evolution of the so-called trau-

matic neuroses. It is not the initial injury but the injury complex from which these patients suffer. Until recently the medical attitude towards these functional troubles has been that of the court room, and therapeutic results as unsatisfactory as the verdicts of the jury. Either the physician has accepted at full value the patient's interpretations of his symptoms, thus crystallizing and perpetuating the "accident complex," or he has regarded these disorders as imaginary or purposely assumed for a monetary consideration, never for a moment visualizing the great significance of the psychic factor in personality. The springing up of the cults was inevitable, a protest against medical obtuseness and short-sightedness. These differing viewpoints not only are unscientific but are unfair to patient and physician alike, representing as they do the opinions of the past thirty years; they now are archaic and obsolete. Functional nervous diseases either arising from or independent of trauma are the manifestation of what Mott calls genetic inadequacy. They may be regarded as a defense reaction because of the inability of the individual to adapt himself to living conditions as they arise from day to day, and the degree of their severity depends upon the way they have succeeded in their life adjustments. It is the psychobiological conception that enables us to estimate not only all the forces but the handicaps as well that are active in the making of personality. And it is through an intelligent perception of these facts that by explanation, therapeutic suggestion, moral suasion, and kindly sympathy—psychotherapy at its best—that we can change the attitude of the patient toward himself, orient him properly, and substitute normal mental reactions for the abnormal. Positive therapeutic results are obtained which at times are almost startling. One of my patients recently referred to her own case as a neurological conversion.

Several years ago a Montana ranch-man, a typical precox, was brought to me. His illness followed immediately an accident—a runaway—in which he was thrown from the buggy, a wheel passing over his head. Several members of his family had been insane. Trauma did not cause this psychosis; it was latent and brought to the surface by the injury. Observation teaches that trauma, exposure, stress and exhausting illness are simply contributory factors. The real cause is genetic inadequacy; without it insanity would not

occur. The experience of Bonhoeffer's Serbian prisoners and the countless gunshot wounds and head injuries of the late war confirm this assertion. The irritability, apathy, depression, alterations in character and associated abnormalities sometimes observed in head injuries and attributed to pathological cerebral changes induced by them, we now know indicate a latent schizophrenia which traumatism has changed from a potential to a dynamic state.

In my final note I shall discuss sleep as a menace. Michael Foster's definition that sleep is a "blank and a gap in the history of the mind" is old, but not obsolete. Of the many explanations of sleep the electric theory of Duval,²¹ the toxic theory of Pieron, the sarcolactic acid theory of Pryer, the cerebral asphyxia theory of Flugler, the anemic theory of Howell, the fall of blood pressure of different writers, are the more important. The most recent, the most notable, the most promising, is that of the Russian School.²² The cortex, according to this, is the seat of two contending activities—excitation and inhibition. Our behavior represents a balance between these two. "Sleep is a spontaneous irradiation of inhibition over the cortex."

There are some chapters of my professional life I would gladly rewrite, especially those relating to disturbed sleep and terrifying dreams. In many instances these experiences are so distressing that patients regard the coming of night with apprehension, often with terror. They resort to every subterfuge to fight off sleep. This action on their part has seemed to me until recently unreasoning—the senseless vaporings of one lacking in proper nervous control. There are certain medical facts common to all. We know that vitality is at its lowest ebb in the early morning hours and in grave illness it is at this time that death is most likely to occur. Schneider, in a total of nearly 58,000 deaths, found that its occurrence was most usual between 4 and 7 A. M. Watson and Finlayson, dealing with the records of nearly 18,000 deaths, placed the highest mortality between 5 and 6 A. M. (MacWilliam). We know that in normal sleep there is a lowering of blood pressure, a slowing of respiration, circulation and glandular activity, a reduction of bodily temperature and of metabolic processes with a diminution or loss of the reflexes. Different observers record a definite fall of blood pressure varying from 15 to 30 mm. Hg. at the

end of two hours' sleep, rising again in the latter part of the night. In hypertension, Brooks and Carrol have noted a fall of 44 mm. after 2 hours' sleep, to rise on waking to 22 mm. We know that the recumbent position, because of the hydrostatic factor, unless there is a fall in the aortic pressure, increases the tension in the cerebral arteries. The use of the pillow under certain pathologic conditions is a wise provision, both for comfort and safety. There were some things regarding this that until Prof. MacWilliam²³ of Aberdeen published his researches we did not know. We did not know that disturbed sleep and dreams raised the blood pressure and caused grave heart irregularities. Sleep to me has meant quiescence, rejuvenation, restoration of bodily and mental capacities. I had not realized that under certain pathologic conditions it was a tragedy. Sleep, aside from dreams, may be disturbed in various ways. Afferent impulses passing along the pathway of the vegetative nervous system from thorax, abdomen and pelvis are perturbing influences of real import. The emotional tone of our complexes is most disturbing, according to Cannon; it increases the adrenal tide and causes an abnormal reaction. A dream is psychic energy unleashed, without control, acting at caprice. It is the resultant of suppressed complexes or some dominant recent experience manifesting itself in the activities of the subconscious when consciousness is in abeyance. In sleep²⁴ the barriers between the conscious and the subconscious are lowered and these activities rise into consciousness, causing dreams. This invasion of consciousness may be light and leave no memory, or it may lessen the integration of personality so as to leave a dim or vivid memory. A nightmare is a dream dynamic. Freud's theory of dreams is a mental phantasy, ingenious, but unconvincing. When dreams are associated with the somatic impulses traveling sympathetic pathways, their tendency to raise the blood pressure, disturb heart action and rupture cerebral arteries is greatly intensified. When called in the night to see a patient who has had a cerebral hemorrhage, there has arisen in my mind, as in yours, the question asked by Sir Samuel Wilks many years ago, and never answered, "Why should this have happened during sleep?" The same inquiry, says MacWilliam, applies to pulmonary, gastro-intestinal hemorrhages and sudden death in supposedly healthy

persons, all of which frequently have a similar incidence. Had the hemorrhages or death followed emotional stress or muscular strain, the explanation would be apparent, but occurring at a period when systolic pressure is low and arterial tension at a minimum, their occurrence would be inexplicable, were it not that MacWilliam has demonstrated the influence of disturbed sleep and dreams in the causation of hypertension and grave cardiac irregularities, which, occurring in persons with cardio-vascular disease and a weakened myocardium, are sufficient to cause the hemorrhages, anginal attacks or fibrillation of the ventricles. A vivid dream, according to him, may cause a marked rise in the blood pressure with associated circulatory and respiratory disturbances in persons all out of proportion to that caused by ordinary exercise, as in walking, cycling, slow ascent of stairs, mental stress or muscular strain gradually taken. While these somatic accidents are exceptional, the fact that they do occur should ever be kept in mind. All pernicious afferent impulses should be prevented, if possible, and emotional stress eliminated, ever keeping in mind the words of Brutus, "Since Cassius once did whet me against Caesar, I have not slept." In a large majority of our patients, arterial degeneration and myocardial insufficiency does not obtain, but in them the resulting nervous manifestations are nevertheless most distressing. We can be of real service by an intelligent perception of the relation of sleep disturbances to their nervous symptoms, by extending a kindly sympathy, not censure, as in our ignorance we have too commonly done, by guarding the pathway of the vegetative nervous system, by correcting endocrine unbalance and by estimating at their full value the psychic factors that upset the physiological processes in the brain cells. We can in this way correct an hitherto unrecognized clinical condition and by instilling peace and calm in the place of anxiety and unrest, order will spring out of chaos and thus, by a tardy justice, we save our medical souls.

In closing these notes, a quotation from the Harveian Oration of 1923 describes more happily than I am able to do the progress made by medicine during the span of my professional life. "I feel," says Prof. Starling, "that I have had the good fortune to see the sun rise on a darkened world, and that the life of my contemporaries has coincided not with a renaissance but with a new

birth of man's power over his environment and his destinies unparalleled in the whole history of mankind."

THE KETOGENIC DIET IN THE TREATMENT OF EPILEPSY*

M. G. PETERMAN, M.D.

Section on Pediatrics, Mayo Clinic
Rochester, Minnesota

A preliminary report[†] on the use of a ketogenic diet in the treatment of epilepsy was published recently, and included the results of such treatment in seventeen cases. Of the fifteen patients from whom reports had been received, ten had been free from attacks for from two months to one year, four had shown remarkable improvement, and one had not responded favorably to the treatment. It is proposed at this time to present the further progress of the fifteen patients, and to report the results in the treatment of five additional patients.

The ketogenic diet, as described in the report mentioned,[†] consists of a large amount of fat with minimal amounts of carbohydrate and protein. Its object is to produce a ketosis evidenced by acetone and diacetic acid in the urine. The total calories should not exceed the actual metabolic requirements of the patient. The basal metabolic rate (determined directly, or calculated from the DuBois normal standards) is obtained, and the allowance of food is made to equal 130 to 150 per cent of the basal caloric exchange of twenty-four hours. After a few days of gradual carbohydrate restriction, the patient is put on a diet of from 10 to 15 gm. of carbohydrate a day, 1 gm. of protein for each kilogram of body weight, and sufficient fat to supply the remaining caloric requirement. Provision is made for the vitamins and salts. This diet is not well tolerated if started abruptly.

Newburgh and Marsh proposed a similar diet in the treatment of diabetes mellitus. These authors fed adults diets of carbohydrate, 14 gm., protein, 10 gm., and fat, 90 gm., the total calories amounting to 900 or 1,000. After the urine was sugar-free, the diets were further modified to carbohydrate, 15 to 20 gm., protein, 23 gm., and fat, 140 gm. Some of these patients have been on the high fat diets for more than four years.

Marsh and Waller showed that the lipemia in diabetes was diminished when the patients were fed high fat diets. Thus, in spite of the ingestion

*Read before the Northwest Pediatric Society, August 2, 1924, Rochester, Minnesota.

DIET 1, 967 calories (carbohydrate, 50 gm., protein, 25 gm., and fat, 71 gm.)

<i>Breakfast</i>	<i>Gm.</i>	<i>Dinner</i>	<i>Supper</i>	<i>Gm.</i>
Fruit, 10 per cent,		Clear broth1 cupful	Bread, white 10	
Strawberries100		(no food value) <i>Gm.</i>	Bacon, weighed uncooked..... 10	
Bread, white 10		Roast beef, lean..... 26	Vegetable, 5 per cent,	
Egg (1), soft boiled.....		Vegetable, 5 per cent,	Asparagus100	
Butter 4		Tomatoes 50	Fruit, 10 per cent,	
Milk, whole100		String beans 50	Orange 60	
		Fruit, 10 per cent,	Butter 4	
		Peaches100	Cream, 40 per cent..... 50	
		Butter 4		
		Cream, 40 per cent..... 50		

DIET 2, 990 calories (carbohydrate, 39 gm., protein, 21 gm., and fat, 80 gm.)

<i>Breakfast</i>	<i>Gm.</i>	<i>Dinner</i>	<i>Supper</i>	<i>Gm.</i>
Fruit, 10 per cent,		Vegetable soup*1 cupful	Bacon, weighed uncooked..... 15	
Orange100		<i>Gm.</i>	Vegetable, 5 per cent,	
Bread, white 10		Vegetables, 5 per cent,	Spinach100	
Egg (1), poached.....		Lettuce 50	Fruit, 10 per cent,	
Butter 9		Cauliflower 50	Peach 20	
Milk, whole100		Fruit, 10 per cent,	Butter 4	
		Pineapple 50	Cream, 40 per cent..... 50	
		Cheese, American (pale)..... 10		
		Butter 5		
		Cream, 40 per cent..... 50

DIET 3, 1,019 calories (carbohydrate, 20 gm., protein, 20 gm., and fat, 92 gm.)

<i>Breakfast</i>	<i>Gm.</i>	<i>Dinner</i>	<i>Supper</i>	<i>Gm.</i>
Fruit, 10 per cent,		Bacon, weighed uncooked..... 10	Egg yolk 1	
Orange 50		Olmsted bran cake..... 1	Vegetable, 5 per cent,	
Olmsted bran cake*..... 1		Vegetable, 5 per cent,	Spinach100	
Omelet (1 egg).....		Celery 25	Olmsted bran cake..... 1	
Butter 6		Tomatoes 75	Fruit, 10 per cent,	
Cream, 40 per cent..... 35		Fruit, 10 per cent,	Peach 30	
		Strawberries 30	Butter 6	
		Butter 7	Cream, 40 per cent..... 30	
		Cream, 40 per cent..... 35		
		Diabetic jello 60		

*See Recipe 9, Diabetic Primer

DIET 4, 1,017 calories (carbohydrate, 10 gm., protein, 18 gm., and fat, 97 gm.)

<i>Breakfast</i>	<i>Gm.</i>	<i>Dinner</i>	<i>Supper</i>	<i>Gm.</i>
Fruit, 10 per cent,		Clear broth1 cupful	Clear broth1 cupful	
Orange 25		<i>Gm.</i>	<i>Gm.</i>	
Egg (1), scrambled.....		Chicken, roast 24	Bacon, weighed uncooked..... 20	
Butter 6		Vegetable, 5 per cent,	Vegetable, 5 per cent,	
Cream, 40 per cent..... 50		Celery, weighed uncooked.... 50	Lettuce and tomatoes..... 50	
		Butter 5	Butter 5	
		Cream, 40 per cent..... 50	Cream, 40 per cent..... 50	

of abnormally large amounts of fat, there is no increase in the blood fat.

The work of Newburgh, and that of Wilder and Winter, demonstrates the practicability and relative harmlessness of greatly restricted carbohydrate

diets for diabetic patients. Since patients with epilepsy have no evident metabolic disorder, they are even better equipped to metabolize food mixtures such as those here suggested.

Miss Foley, dietitian at the Mayo Clinic, has

submitted sample diets which demonstrate the method of carbohydrate restriction. Attention is also directed to the sample diets given by Newburgh and Marsh.

If desired, the butter allowed in the diet may be added to the clear broth. Saccharine diabetic flavoring and water may be added to the cream to make a more palatable beverage.

Every diet prescription must be created for the individual, varying as do prescriptions for diabetic patients. Patients are given the diet prescription, and then sent to the Diet Kitchen to consult the dietitian, who carefully instructs the child or his guardian as to the purpose of the diet. A Diabetic Primer, which is used as a textbook, is supplied. The general principles of the diet are outlined the first day; then classes are held in which the weighing of food is demonstrated, and the patient given an opportunity to become familiar with the weight and composition of foods, the weight of the servings, and the allowances of carbohydrate, protein, and fat. After several such lessons, the patients or guardians are required to work out sample diets.

Ten patients have now remained free from attacks for periods varying from five to fifteen months. Of the four patients who, at the time of my previous report, had shown marked improvement but not complete relief, two (T. F. and G. K.) have now been entirely free from attacks for three months. The other two patients are still subject to occasional convulsions. One of these, who has had severe mental trauma, suffers from hysteria; it has not been possible to learn whether the ketosis is present in the other patient. The father of the latter has been under treatment for syphilis. The one patient who has shown no improvement is a post-encephalitic, undergoing mental degeneration (as mentioned in the preliminary report).

Five new patients, ranging in age from four to ten years, have been on the ketogenic diet for more than one month. All five, three with petit mal, and two with both petit and grand mal, are entirely free from convulsions. The two latter patients are also receiving luminal.

Five patients, including T. F. and G. K. already mentioned, did not respond immediately to the ketogenic diet, in spite of a severe ketonemia. These patients, therefore, were put to bed on a starvation diet, consisting of three to five oranges

a day and water *ad libitum*. After one week of such starvation, the attacks ceased and the children were again placed on the ketogenic diet. They have remained free from further attacks; T. F. and G. K. have been free for three months each.

All of our patients, except T. F. and G. K., have remained healthy and strong. These two boys each had one gastro-intestinal upset, during which they refused all food for several days. G. K. became weak and lost weight. They were given general diets with restricted carbohydrate, less than 50 gm. a day, for one week, and were then put back on the ketogenic diet. Both remain free from attacks. All of the other children have gained weight, and are reported to be very active mentally.

One patient, R. E., remained on the ketogenic diet for two years; during this time he had three grand mal convulsions. Each attack was preceded by a break in the diet. The last attack occurred fifteen months ago. He was put on a general diet nine months ago, and has had no further difficulty.

J. C. had three attacks during the first two weeks on the diet. Six months later he was given a ratio of 2:1 ketogenic to antiketogenic molecules, and is now approaching a general diet. He has had no attacks for ten months.

CONCLUSIONS

The results of treatment with the ketogenic diet in twenty cases of epilepsy, nine of petit mal, six of grand mal, and five of grand and petit mal, are given. Three of the cases may well be omitted, because the convulsions are better explained on an organic basis. The remaining seventeen patients are now on the diet, and acetone and diacetic acid are evident in the urine. These seventeen patients are entirely free from epileptic convulsions. The most favorable results have occurred in cases of petit mal.

Studies of the blood chemistry have not been completed.

The treatment of epilepsy with the ketogenic diet has given excellent results, and should be given a thorough trial.

SPREAD THE PROPAGANDA FOR HEALTH

The purpose of the American Medical Association in publishing *Hygeia* is to give authoritative information to the public about matters of health. The more widely such information is disseminated, the better. Therefore the reprinting of items from *Hygeia* by newspapers, magazines or reputable publications of any sort is welcome.

A clip-sheet is prepared each month containing "boiled down" summaries of the articles appearing in the issue of the magazine for that month. The clip-sheet will be sent promptly and regularly to any newspaper requesting it, or to any Fellow of the Association who will undertake to interest the editor of his local newspaper in reprinting items from the clip-sheet or from the magazine. It is expected that mention will always be made that the item is from *Hygeia*.

The Fellows of the American Medical Association to whom the Bulletin is sent can be of great service in extending the propaganda for health by this means. The physician practicing in any community is better qualified than anyone else to select those items of health propaganda that will be of the most interest and importance to the people of his locality at a given time. He should have little difficulty in convincing the editor of the local newspaper of the advantage of printing such health items, sometimes, perhaps, with added comment to fit the article to local conditions.

Send for the Hygeia clip-sheet, and use it.—A. M. A. Bulletin, Dec., 1923.

ANOTHER FULL-TIME STATE SECRETARY

The Michigan Medical State Society, at its annual meeting at Mt. Clemens, amended its constitution and by-laws to fix the annual membership dues at \$10. This was done to provide for the employment of a full-time secretary and to enable the society to extend its work and increase its usefulness. Thus the Michigan State Medical Society has again recorded itself as an organization that refuses to stand still or even to move slowly in discharging its recognized duties to its members and its state. It may be confidently predicted that the results attendant on this progressive action will entirely justify it and that the benefits to be derived will not be long in being realized.

Since the West Virginia State Medical Association recently provided for a full-time secretary, too, there are now at least nine state associations with full-time secretaries: Massachusetts, West Virginia, Virginia, Wisconsin, Ohio, Texas, Missouri, California and Michigan. Pennsylvania has a secretary and a full-time executive secretary.—*A. M. A. Bulletin, October, 1924.*

REMINISCENCES OF THIRTY YEARS AGO*

P. G. COWING, M.D.
Evansville, Minn.

Mr. President, and Gentlemen:

When called upon, by the program committee, to prepare a paper for this evening, I spent considerable time trying to select a suitable subject. And realizing that the scientific subjects could be handled very much better by other members of the society, I finally decided to go back thirty years and give you some of the impressions, made upon the "callow mind" of an interne, which time has failed to efface.

We hear and read daily of the wonderful work being done by the leading men of the profession today, but do we ever stop to think that they are only carrying on, a little farther, the work begun thirty or thirty-five years ago by those pioneers, some of whom it is my intention to mention to-night. The advances made in laboratory facilities and the use of the x-ray have made the matter of diagnosis exceedingly simple as compared with the methods in vogue at the time about which I am writing. The men of that day had to depend upon touch, sight and hearing together with a good knowledge of human nature and a large amount of common sense in arriving at a diagnosis. Yet, I stand ready to affirm that, with only their limited facilities, their work compares favorably with that being done today, and in some respects excelling a considerable amount of what is called surgery as we see it now. Did you know that the first operation, performed in this country, for the removal of a goiter was performed by Dr. Knute Hoegh of Minneapolis more than thirty years ago? That the first cholecystotomy in the state was done by a St. Paul surgeon, Dr. Justus Ohage, more than thirty-two years ago?

I could enumerate a number of operations, which are quite common today, that were performed by these pioneers in surgery and with very little difference in technique. However, I am not going to give you a scientific dissertation on the surgery of thirty years ago as compared with that done today, but am going to give you some of the personalities of a few of the surgeons with whom I came in contact while serving my internship at St. Joseph's

*Presented before the Northern Minnesota Medical Association, Duluth, August, 1924.

Hospital, St. Paul. in 1893. This was during what may be called the antiseptic period of medicine, as more attention was paid to antisepsis than asepsis. Dr. W. W. Price was the leader in the introduction of asepsis, but it had not, then, been generally adopted in the west.

The first man I am going to mention is Dr. J. H. Murphy. He was of the "old school," a graduate of Rush Medical School at the time they turned out finished M.D.'s after a twelve weeks' course, to get the most of their training on their fellow men. He soon enlisted, after graduation, in the U. S. Army and served as a surgeon throughout the Civil War. At the time I first met him he was surgeon for four railroads and of one was surgeon-in-chief. He worked only on the extremities, as the abdomen was a *terra incognita* to him. He was a large, portly man and always wore a Prince Albert coat with a high silk hat. If he did not get what he called laudable pus in a wound after operation something was the matter. When an accident case from the railroad shops came in, Dr. Murphy usually arrived before the ambulance. Hurrying into the emergency operating room, he would take off his coat, roll up his sleeves and, opening his old kit bag, extract from it a large rubber apron, which he would don. Then he would fish out an old operating case and take from it a large scalpel, two or three needles, a spool of silk thread and one or two pairs of artery forceps and a pair of scissors, all of which he would lay out on a small table near the operating table. Then, scalpel in hand, he would go out in the hall and wait for the patient to arrive. He would then, as soon as the patient was asleep, start in cutting and fixing up the injury. Our surgical nurse, who was a graduate of the Presbyterian Hospital of Chicago, would stand by with the nozzle of a 5-gallon irrigator full of a bichloride solution and turn the stream on the field of operation until the wrath of the doctor would rise and he would tell her to turn off that squirt gun as he did not want to be drowned. Finishing the operation he would tell us to put on a dressing and would himself wipe his instruments on his sleeve and return them to his bag ready for another emergency. As a prognostician he was excelled by few. He was a kindly old gentleman, who knew his limitations, but was too old to adapt himself to the new order of things. One other incident in connection with Dr. Murphy and I will pass on to others. When he was taken with the

illness which resulted in his death, he called a consultation of all the leading doctors in the Twin Cities. They decided that an operation for the relief of the carbuncles with which he was afflicted would have to be performed and left it to him to select the operator. He chose an eye and ear man to do the work.

We had an unusual opportunity at St. Joseph's to observe the different methods illustrative of the different countries in which the doctors had received their training. From Norway we had the brilliant Dr. Harold Graff, whose post-operative care of his patients could not be excelled. He once told me that he had spent ten years intensive study in the hospitals before he ever attempted to operate. His death was as dramatic as his life was erratic. I can well remember the deputy coroner calling me up and asking me to assist him at an inquest and, upon arriving at the place, being told that Dr. Graff was the subject. The body was lying on a couch and nearby stood a table, with a large hypodermic syringe, not quite empty, lying on it. Upon examining the body we found that he had carefully injected cocaine solution into the skin over the heart and then had thrust an amputating catlin into that organ, causing instant death. Whiskey and domestic trouble proved more than he could stand. Among the doctors educated in Germany we had Dr. Justus Ohage, who was as jealous of his reputation as a young girl of her first beau. He was and is a skillful operator and performed a large number of gallbladder operations, several resections, and made common use of the "Senn" bone plates in those years. Dr. Arnold Schwyzer, still living, was and is a surgeon from whose work the very best can derive many valuable lessons. An exceptionally fine pathologist, and clever operator, I would advise all of you gentlemen never to neglect to see him work, if you have the opportunity. Dr. Canac Marquis, educated in Paris, exhibited all the excitable tactics of the French. His motto was, "Cut and tie afterwards." He was a bold and a bloody operator, yet one could not help but admire his fearlessness in his work.

I now come to the men educated in America. Alex J. Stone, M.A., M.D., LL.D., was well known internationally as well as in this country, as one of the leading gynecologists. He was considered in the class with Sims, Munde, Thomas and some others. He was one of the wittiest, as well as one of the best clinical instructors of his day. He was

always ready to extend a helping hand to assist a needy student or brother practitioner, and was one of "God's own noblemen." The world is the better for his having lived. An instance illustrates his interest in the students. At some time in his earlier career, he met with an accident, a horse falling with him and dislocating his leg at the hip. It was not replaced for some time for some reason and afterward he could, by a sudden twist, dislocate it again. I have seen him voluntarily do this painful procedure, before a class of students, to illustrate upward and backward dislocation for their benefit. Dr. Archibald MacLaren,* known to you all, was at this time coming into his own and by his careful, scientific methods advancing to the place he holds today. He was the coolest man that ever leaned over a patient on an operating table. Nothing could excite or hurry him. Always exact and by his follow-up methods keeping in touch with his cases after they had left his hands, he was able to correct details in technique and profit by his experience. You can no longer wonder at his success.

The last of the St. Paul men I am going to mention, as I have not the time nor you the patience to listen to a detail of the various specialists, is Dr. C. A. Wheaton. When he was a young man he was employed as baggageman on the Milwaukee R. R., and, while on a hunting trip, was accidentally shot in the hip. He very nearly bled to death before assistance could be obtained. This made such an impression on him that he resolved to study medicine, which he forthwith did. Graduating from Harvard Medical College, he became professor of anatomy in the St. Paul College of Medicine, which position he held until its affiliation with the University. He there laid the foundation for his skill as a surgeon. He became the leading surgeon in the state and his services were in great demand. He had a great personality and could inspire confidence in the most despondent patient. Always jealous of his reputation, he never left any loopholes for trouble to creep in. He watched the progress of his assistants just as carefully and never left any stone unturned to perfect them in their chosen field. Many a young doctor can point to the foundation of his success in the instruction received from him.

Among the Minneapolis surgeons with whom I came in contact while a student in the office of

Dr. James H. Dunn, I will mention Dr. Knute Hoegh, a graduate of the University of King Fredrick, Norway, in 1859. He practiced at several points, finally locating in Minneapolis, where he enjoyed a very large practice. He was an exceptionally good diagnostician and more than an average surgeon. He was a very witty man and his sallies were so unexpected. To illustrate, while temporarily acting as interne at St. Mary's Hospital, it was my painful duty to inform him one morning, upon his arrival at the hospital, that one of his medical cases had died during the night. He stood for a moment or two, then said, "My medical cases are in the hands of the Lord; but my surgical cases I have something to say about them." On another occasion, when in consultation with a very young doctor, noting the anxiety on the part of the young man, he took him by the shoulder and said: "Ninety-five per cent of all medical cases will get well without any medicine, and I have my doubts of the other 5 per cent." He had a very bad temper which he never tried to control, and which very frequently got him into bad predicaments. Once, his assistant having forgotten to bring from the office a certain instrument which he needed, he let himself loose, abusing everyone present; the hospital interne faced him and told him not to say anything to him or he would shove his fist down his throat, that he had always treated him as a gentleman and expected the same from him. Dr. Hoegh looked him up and down and said, "I guess you can do it, I apologize," and everything was lovely again. While with Dr. Dunn I witnessed an unusual performance, namely, four separate operations, performed by four surgeons on the same patient at the same time. The patient belonged to Dr. Hoegh. She had tuberculous enlargement of the glands in both groins and in both sides of the neck. Owing to her weakened condition, the patient could not stand a prolonged operation, or more than one, so Dr. Hoegh secured three of the leading surgeons to help him. Dr. Dunn and Dr. J. E. Moore operated on the groins while Dr. Dunsmoor and Dr. Hoegh operated on the neck. The patient lived. Dr. Hoegh was a born clinical instructor and it was unfortunate that petty jealousy of one or two men kept him off of the staff at the University. He used to hold private clinics to which he invited a few students and I am sure they will never forget the large amount of valuable instruction he

*The death of Dr. MacLaren occurred Oct. 12, 1924.

gave them. Dr. J. E. Moore, or "Little Dr. Moore," as he was called to distinguish him from Dr. J. T. Moore, was at this time an orthopedic surgeon. He was very rapid in his work. I have seen him amputate a leg when it took only forty-five seconds from the time he made his first incision until the limb was severed and he was ready to tie the arteries. Some record! It was always a pleasure to see him work.

Dr. James H. Dunn, with whom I served a term while a student, was probably the finest diagnostician in the Northwest. He was thoroughly prepared for work in his chosen field, and had rare good judgment. He often said it was not how, but when to cut, that counted. His continued hard study and the extremely large amount of work he did, proved too much for his delicate physique, especially after a narrow escape from death from blood poisoning had weakened him. The profession lost one of its most valuable members when he dropped dead at the meeting of the American Medical Association at St. Louis.

I have mentioned only a few of the leading men of thirty years ago, for there were many more. These men worked under a great handicap. Dr. Boeckmann had not invented his sterilizer which revolutionized the preparation of dressings. Nor had he perfected his process for sterilizing by dry heat, upon which the surgeons of today depend for sterilization of ligatures and sutures. Silk was used almost exclusively for buried sutures and they very often caused trouble. The catgut ligatures prepared in those days by immersion in a strong antiseptic solution had a tendency to break, the antiseptics destroying the strength, and they were not always sterile. The mortality among the operative cases was very little higher than now. I will say in conclusion, that we should honor the memory of these pioneers in surgery, and may we all profit by the good work performed by them.

Gentlemen, I thank you for your kind attention.

THE FORTHCOMING U. S. PHARMACOPEIA

The committee elected in May, 1920, for the revision of the United States Pharmacopeia has practically completed its work. The responsibility for the scope of the new book was placed on the twenty-one physician members of the committee so that the new edition should be more fully representative of the therapeutically valuable drugs than formerly. The number of medicinal substances to be included in the book is less than 650.—(*Jour. A. M. A., Sept. 20, 1924, p. 923.*)

THE USE OF FULL THICKNESS SKIN GRAFTS*

GORDON B. NEW, M.D.

and

FRED A. FIGI, M.D.

Section on Laryngology, Oral and Plastic, Mayo Clinic
Rochester, Minnesota

Free, full thickness skin grafts have been used for many years, but, owing to the low percentage of good results following their use, a great many surgeons have gradually abandoned them. On removing the dressing from three to four days after operation the graft usually appeared to be doing well, but in a few days it gradually began to grow dark, and ultimately sloughed.

Keller first called our attention to the value of large, full thickness skin grafts, emphasizing the use of dental modeling compound as one essential in obtaining even pressure over the graft. Parce, in 1922, working with Keller, reported eight cases, and pointed out the use of such grafts in scars and contractions about the arms and feet following war injuries. In one of his cases a graft was applied to an anus after the removal of an epithelioma.

Fig. 1 (Case A460282). Ectropion of the lower lip from a burn.

Fig. 2 (Case A460282). Postoperative. A full thickness skin graft has been inserted after a portion of the mucous membrane, as well as the scar, has been excised.

We have used full thickness grafts around the face and neck whenever there was sufficient supporting tissue to allow firm pressure after operation, such as in filling in the defect after excision of scars, or following the excision of an inactive basal cell epithelioma if a plastic closure was not

*Read before the meeting of the Northern Minnesota Medical Association, Duluth, August 4-5, 1924.

possible, in correcting ectropion of the lips, and in grafting the distal end of a pedicled flap if a double epithelized flap was essential, as in reconstructing the nose, cheek, or lower lip. We have also used the grafts in replacing large, pigmented, hairy moles on the face, and by means of a rubber

Fig. 3 (Case A463452). Low grade epithelioma of the forehead and bridge of the nose.

Fig. 4 (Case A463452). Postoperative. The epithelioma was excised and immediately replaced with a full thickness skin graft.

tube, in lining scarred-down nostrils. Usually they have been applied to clean wounds, but when used in correcting ectropion of the lower lip, slight secondary infection has sometimes occurred, due to the location.

Local anesthesia is used, as a rule, except for children, both in removing the graft and in preparing the area to be grafted. At first it was feared that the local anesthesia might interfere with the success of the graft, but the grafts do as well with local anesthesia as with general.

The area to be grafted must be freed from fat as much as possible, so that on the neck it is best to get down to muscle or some such tissue to make a bed for the graft. In order to render the area to be grafted as dry as possible, the vessels are pinched off with forceps and the oozing controlled with hot sponges. Very little catgut is used, as it tends to prevent the accurate approximation of the graft to the underlying tissues. The margin around the area to be grafted is undermined so that it may be approximated accurately with the margin of the graft.

Small grafts for the face can be best obtained from the posterior cervical region, as the color of the skin is more like that of the face than that in other parts of the body. The larger grafts are taken from the thigh or upper arm. Round or oval grafts are more accurately approximated to

the margins of the area to be grafted. The full thickness grafts, the thickness of the true skin, are dissected with a knife and cut as thin as possible, care being taken to avoid fat. If small areas of fat are attached to the graft, these are cut away with scissors. If hair-bearing skin is to be used, a deeper graft is necessary, but the chance of success is not nearly so good as with the usual thin, full thickness graft. The graft is cut as nearly as possible the size of the area to be grafted so that in its new position it will be under normal tension. A pattern of the area to be grafted may be made with rubber tissue, or it may be measured. We have used grafts as large as 7.5 cm. in diameter, but it is not advisable to use larger grafts on account of the difficulty in maintaining even pressure over the entire area. It is better to apply several small grafts at different times than to attempt a large one, especially on the neck. The graft is sutured in place accurately with dermal sutures, and is not perforated. Several layers of gauze, about 1.5 cm. in thickness, just a little larger than the graft, are applied and firm pressure made by means of adhesive plaster, thus splinting the graft in its new position.

The dressing is not touched for ten days, and then, in order not to disturb the graft, is removed carefully in layers. As a rule, the graft will have adhered perfectly, and require no further treatment. The wound is left open to the air and protected for

Fig. 5 (Case A460095). A dark pigmented scar of the cheek from a burn.

Fig. 6 (Case A460095). Postoperative. The greater part of the scar was excised and replaced with a full thickness skin graft.

a time with a wire mesh basket. If the graft is applied over the malar bone, the forehead, or the bridge of the nose, a small slough may occur over the most prominent bony point if too much pressure is applied. Sometimes one or two small

superficial areas may slough and make it necessary to dissect them off; these areas will epithelize themselves. If this technic is followed, the greater number of full thickness grafts will be successful.

Fig. 7 (Case A234391). Scarring of the neck and chin from a burn. Note the very short neck.

Fig. 8 (Case A234391). Patient six years later, following the use of radium and full thickness skin grafts over the neck. Later a full thickness skin graft will be used to correct the ectropion of the lip.

We have found that dental compounds, applied directly to the graft, tend to macerate it, and therefore we prefer the gauze. Blair uses silk sea-sponge for pressure. The sponge is applied moist, and when removed is quite dry and hard. Davis recommends silver foil and dry gauze, or gauze kept moist constantly with salt solution, or a flexible paraffin mixture such as ambrine. He believes that the area should be immobilized until the blood supply of the graft is assured, and the parts protected from trauma for about six weeks.

If the area to be grafted is on the neck, the patient is kept flat on his back for at least ten days, with shot bags on either side of the neck, which aid in keeping the part absolutely immobilized. It is not advisable, as a rule, to try full thickness grafts on the necks of very young children because of the difficulty in keeping the part quiet for the necessary period, but if they are attempted, the child should be put in a Bradford frame.

Full thickness grafts, in suitable locations, have certain definite advantages over the pedicled flaps. As a rule, the patient is in the hospital about ten days or two weeks, whereas if a pedicled flap is used, the hospitalization period is usually from six weeks to two months, the full thickness graft saving the patient much time and expense. Also, there is much less possibility of infection, as the operation is done in one stage. The tissue lies flat and is under tension in its new position, whereas in the pedicled flaps the tissue is usually thickened

like a pillow. Full thickness grafts have certain advantages over Thiersch grafts when used in locations in which they are indicated. They give much more body to the pedicled flaps than the Thiersch grafts, preventing them from drawing up on themselves. Around the face the cosmetic result is much better, the color and the thickness of the skin being more like the surrounding tissue. In some cases there is slight pigmentation for the first few months, but in most cases the color is so nearly normal that ultimately it is difficult to tell the graft from the surrounding tissue (Figs. 1 to 10).

Fig. 9 (Case A437320). Scarring of the neck and ectropion of the lower lip from a burn.

Fig. 10 (Case A437320). Postoperative. A full thickness skin graft has been inserted in the anterior part of the neck, after excision of the scarring. Part of the mucous membrane of the lower lip, as well as a portion of the skin, has been excised and replaced with a full thickness skin graft to correct the ectropion.

CONCLUSION

Full thickness grafts are of definite value if used on the face and neck where firm pressure can be applied. The essential points are: (1) a clean, dry wound, free from fat, (2) a graft free from fat, the same size and shape as the area to be grafted, (3) accurate suturing of the graft, (4) firm pressure applied with gauze for at least ten days, and (5) immobilization of the parts during this time.

Did you ever stop to think that the names of diseases and the names of flowers are very similar? For instance, I might say, "Do come and see my garden. It is at its best now, and the double pneumonias are really wonderful. I suppose the mild winter had something to do with that. I'm very proud of my trailing phlebitis, too, and the laryngitis and deep purple quinsies that I put in last year are a joy to behold. The bed of asthmas and malarias that you used to admire is finer than ever this summer, and the dear little dropsies are all in bloom down by the lake, and make such a pretty showing with the blue of the anthrax border behind them!"—From *Madame Claire*, by Susan Ertz.

A RATIONAL AND SIMPLE METHOD OF FEEDING CHILDREN DURING THE FIRST TWO YEARS OF LIFE

CHESTER A. STEWART, M.D., and
ERLING S. PLATOU, M.D.

Assistant Professor and Assistant in Department of
Pediatrics, Respectively, University of Minnesota

Minneapolis

When one considers the great rapidity with which growth occurs normally during the first two years of life and also the prevalence of nutritional and gastro-intestinal disturbances during this period, the importance of the proper supervision of the diet of young children becomes apparent. It is physically impossible and probably not desirable for this important phase of preventive medicine to be undertaken exclusively by the few physicians limiting their practice to pediatrics. Undoubtedly the vast majority of mothers must rely upon their family physician for common-sense supervision of diets for their children. This affords the physician an opportunity to exert an educational influence in his community which should result in better and healthier babies. It is undoubtedly highly desirable that young mothers and also those with experience should obtain information regarding the care of their children from the informed and experienced physician rather than from a well meaning but uninformed neighbor or friend.

Physicians rendering very high-class service in general practice have informed us that in general they give better service to sick infants than they do to well babies, and feel that a simple outline of feeding for children during the first two years of life would equip them to offer well baby care to their patients. The purpose of this paper is to attempt to meet this need.

Mother's milk is undoubtedly the safest and most satisfactory food for the infant during the first few months of life, and every physician should do his utmost to encourage maternal nursing. In general, clock-like regularity of the frequency of nursing is desirable, and for the majority of infants the four-hour interval between nursings proves very satisfactory and entirely meets the needs of the infant. In some instances, however, shorter intervals between nursing periods prove more satisfactory, although it is seldom necessary

to put the baby to breast oftener than every three hours. As a rule, if the physician instructs the mother to nurse the baby at stated intervals, to awaken it if necessary when the feeding time comes, and not to feed the baby when it cries, the instructions are followed.

For convenience and simplicity in the feeding directions outlined in this paper the four-hour interval is adopted. The same schedule, however, may be adopted when dealing with infants fed more frequently by merely adjusting the hours at which solid foods are given.

In general, four to six hours after birth the baby is taken to breast and permitted to nurse for twenty minutes. As a rule only one breast is nursed at each feeding, and in most instances after lactation is established sufficient milk is obtained from one breast to meet the infant's needs. If the baby is weighed every five minutes while nursing, one finds that the greatest amount of milk is obtained during the first five minutes. After twenty minutes at the breast very little or no milk is obtained, and if weighings are continued at five-minute intervals the surprising discovery is made that the baby actually loses slightly in weight. This loss results probably from the fact that the infant obtained nothing at the breast, and during this interval lost a measurable amount of fluid by evaporation from the skin and also through the expired air. If the physician tries this experiment he will soon be convinced that nothing is accomplished by permitting the infant to nurse much longer than twenty minutes. The normal baby receiving an adequate amount of breast milk will thrive when fed every four hours, permitting only five feedings in twenty-four hours. Many infants will sleep the entire night without nursing between ten P. M. and six A. M. However, if the baby requires a night feeding it should be permitted. Under normal conditions the baby may be fed exclusively on mother's milk until six months of age. After this age the following schedule may be followed:

SIX MONTHS

- 6 A. M. Nurse
- 10 A. M. Farina or cream of wheat; nurse
- 2 P. M. Nurse
- 6 P. M. Farina or cream of wheat; nurse
- 10 P. M. Nurse

Cook cereal three hours, season with salt and add a little sugar.

Feed cereal thick, starting with one teaspoonful and increase gradually to three or four tablespoonfuls twice daily.

SEVEN MONTHS

- 6 A. M. Nurse.
 10 A. M. Farina or oatmeal; nurse
 2 P. M. Carrots, spinach, swiss chard, peas or cocked head lettuce; nurse
 Cook vegetables until tender, season with salt and strain; do not throw water away. Start with one teaspoonful and increase gradually to 3 to 5 tablespoonfuls
 6 P. M. Farina or oatmeal; nurse
 10 P. M. Nurse

EIGHT MONTHS

- 6 A. M. Nurse
 10 A. M. Cereal, toast, buttered, 5 to 6 ounces of boiled, whole cow's milk
 2 P. M. Carrots, peas, spinach, chard or head lettuce. Baked potatoes, meat broth with fat skimmed off, vegetable soup; nurse
 6 P. M. Cereal, toast, buttered, five to six ounces boiled, whole cow's milk
 10 P. M. Nurse
 At eight months start weaning gradually by omitting two nursings

NINE MONTHS

- 6 A. M. Nurse
 10 A. M. Any cooked cereal, toast, six ounces boiled cow's milk
 2 P. M. Carrots, peas, spinach, head lettuce, Swiss chard, tomatoes (cooked), asparagus tips, vegetable soup, baked or mashed potatoes, stewed prunes, baked apple or apple sauce. Six ounces boiled milk
 6 P. M. Cooked cereal, toast, six ounces boiled milk
 10 P. M. Nurse
 At nine months the 10 P. M. nursing may be omitted in many instances

TEN MONTHS

- 7:30 A. M. Cereal, toast, prunes, six to seven ounces boiled milk
 12:30 P. M. Cooked carrots, peas, spinach, Swiss chard, head lettuce, string beans, asparagus tips, cauliflower, tomatoes, celery, Brussels sprouts, baked

egg plant, vegetable soup, meat broth, baked apple, apple sauce, baked or mashed potatoes, six to seven ounces boiled milk

Do not permit any morning lunch between 7:30 and 12:30

3:30 P. M. Orange, toast or zwieback

6:30 P. M. Cereal, vegetable soup, toast, six to seven ounces boiled milk

The majority of babies may be weaned at 10 months of age

TWELVE MONTHS

Add stewed peaches, apricots, apple butter, jam, baked banana, rice, scraped, or ground beef

FIFTEEN MONTHS

Add bread and butter, jelly, jello, cottage cheese, junket, bacon, fried crisp. At fifteen months of age vegetables do not need to be strained

EIGHTEEN MONTHS

Add roast beef, veal or lamb chop, mutton stew, sweetbreads, chicken and other fowl, broiled veal liver, fish, salmon, scraped raw apple. Do not give ham or pork or cured meats

TWENTY-TWO TO TWENTY-FOUR MONTHS

Add poached or soft boiled eggs, simple cookies, desserts containing eggs, tapioca, custard, bread pudding

The above method of feeding children, with minor alterations, is in general use in Minneapolis. Readers undoubtedly will notice that it differs in some details from methods which they employ successfully. The purpose of this paper is not to offer this schedule as the only method of properly adjusting the diet of infants, for the one and only method of feeding normal children does not exist. The adoption of this or some similar systematic plan of directing the diet during the first two years of life is recommended, however, to enable the physician to employ a rational simple and tested method for "well baby care" which will promote proper nutrition and good health for his young patients. At first the physician not accustomed to directing the diet of infants may find reference to the schedule necessary, but with continued use

of a systematic plan, outlining the changes from month to month becomes as easy and commonplace as writing a simple prescription. After thorough familiarity is obtained as to the results obtained through systematic supervision of the diet, the physician will find that through this growing experience, modifications of this simple schedule may be made to meet practically all his needs.

Probably the most common alteration of the dietary regime to be made is the addition of cereal to the diet before the sixth month, for Farina may be given safely as early as the second month, or earlier. In this manner the giving of artificial milk mixtures, which often encourage weaning the baby, may be avoided, and moderate deficiencies in the amount of breast milk may be offset by the simple administration of cereal.

Various other modifications of the diet schedule may also be profitably made when dealing with individual cases, and success in feeding babies will increase with growing experience on the part of the physician in the early addition of solid foods to the diet.

Even under the most favorable circumstances, however, one must occasionally resort to complementary feedings, for which simple dilutions of cow's milk often suffice. For advice as to advisability of using milk mixtures the mother undoubtedly should rely upon the directions of her physician rather than upon directions printed upon the containers of proprietary artificial foods.

The difficulties confronting maternal nursing are almost too numerous to mention, although attention may be called to the solution of a few of these problems. The practice of examining the quality of breast milk is obsolete. A thorough and complete analysis of breast milk in individual cases would undoubtedly consume so much time that by its completion the child would have attained the age of weaning. One can more profitably direct his efforts in determining the maximum amount of milk the individual mother can supply her baby by weighing the infant before and after nursing. If the amount obtained at the breast is inadequate to permit a gain in weight of four to six ounces each week when given both breasts at each feeding, the breasts should be expressed by hand after nursing to make certain that they are completely emptied. Incomplete drainage of the breast favors a diminution in the milk supply if continued over several weeks. Where the baby nurses vigorously

and completely empties the breast only a few drops of milk may be obtained by manual expression. In such instances, the continuance of breast expression is probably of no benefit and not advisable.

Occasionally, considerable breast milk is lost from dripping from the nipple between nursing periods. This may be prevented by wearing glass nipple shells (Fig. 1) collecting this milk in order that it may be given to the baby by bottle or spoon after nursing. The glass shells are applied to the breast with the nipple projecting into the aperture provided for this purpose and are held in position by means of a binder applied snugly around the chest. This very convenient device should be used more widely, for not infrequently patients collect from six to eight ounces of milk daily in this manner. After the third or fourth month of lactation the loss of milk from the breast usually ceases.

GLASS NIPPLE SHELLS

FIG. 1

To promote a maximum supply of breast milk, mothers should indulge in a generous diet without restriction and should be free from worry. In addition, a two hours' rest in bed in the afternoon

and an early hour for retirement at night is advisable.

An insufficient supply of breast milk is no excuse for weaning a baby. Under such circumstances, the infant should receive every drop the mother can supply and be given enough additional food to make up whatever deficiency exists.

In conclusion, it is recommended that all physicians engaged in general practice adopt some simple, rational, tested method of outlining the diet for young children and train their patients to rely upon their own doctor for "well baby care."

In his presidential address before the American Medical Association last June, Dr. William Allen Pusey devoted himself to the subject of the limitation of population, and brought to the support of an argument for birth control most of the familiar facts about the impossibility of supporting the population of the future on the land of the present. "If no effort is made at birth control," said Doctor Pusey, "nature will take charge of the situation by eliminating those less able to resist." Continuing his argument, he cited the contention of the economists that those people inherit the earth who multiply most rapidly, and that fecundity increases inversely according to the individual's position in the social scale. It seemed to him, as it has seemed to others, that this means the downfall of modern Christian civilization, with the triumph of the misery and degradation of Asia. "I particularly desire," he concluded, "that the mistaken impression should not go out that I mean to say that medicine now has any satisfactory program for birth control. It has not."

In the tomes of the ardent economists, biologists, sociologists and philosophers who favor birth control, the eager reader will also search futilely for any practical program, or, indeed, for any practical method. His disappointment will not, moreover, depend entirely on the fact that our government, either wisely or unwisely, has made unlawful the dissemination of such knowledge as is available. The fact is that none of the students of the problem, not even the physicians, have ever perfected any method of birth control that is physiologically, psychologically and biologically sound in both principle and practice. Not, of course, that devices for the prevention of conception do not exist; it is well known that they do, and that they are easily available to almost any purchaser in any drug-store in America. The difficulty lies primarily in the imperfection of the devices themselves, and in the peculiar psychology of that lower stratum of society which the birth-control enthusiasts insist must be brought to the light, lest its descendants inherit the earth.—*Morris Fishbein, The American Mercury.*

THE HISTORY AND PRESENT STATUS OF THE NON-SURGICAL TREATMENT OF HEMORRHOIDS*

W. A. FANSLER, M.D.

Instructor in Surgery, University of Minnesota
Medical School
Minneapolis

The non-surgical treatment of hemorrhoids is not new. It has been described and used for many years. It is only new in the sense that the profession as a whole has very little real knowledge concerning it. The first method of non-surgical cure advanced was that of electrolysis. This procedure originated in Germany over a hundred years ago, but with the advent of aseptic surgery was more or less forgotten. Sir Charles Ball of Dublin later described the method and in 1891 an article by Newman appeared in the Journal of the American Medical Association. As far as I can ascertain, this is the first reference to the subject in American literature. More recently very comprehensive papers have been published by C. C. Mechling of Pittsburgh and H. E. Dunne of Washington. The injection method of treatment is of American origin. In fact, in Europe it is frequently known as the American method. It dates back to 1891, when it was first advocated and employed by a Dr. Mitchell of Illinois. Since that time, more particularly in the last ten or fifteen years, there have been numerous descriptions of the method appearing in both domestic and foreign medical publications.

That the method has not been more widely adopted is in my opinion due to two factors: first, a lack of adequate information concerning the treatment, and, second, to prejudice which has been handed down from one medical generation to the next. When the injection method was first devised the profession as a whole gave it but little attention and waited for the proof of time. Unfortunately, the quacks were quick to see that the people in general would welcome any method which was said to cure with little pain and without operation. Literally hundreds of irregulars went about the country making preposterous claims and injecting all who came their way. They were frequently unscrupulous and of little medical attainment. Their knowledge of rectal diseases and aseptics was

*Presented at the meeting of the Northern Minnesota Medical Association, Duluth, August, 1924.

limited. The natural results were numerous complications and some deaths. The remarkable thing is that even under these conditions numerous cures were produced.

Had there been any considerable number of ethical physicians practicing proctology at that time no doubt the matter would have received thorough investigation and its real value determined. Unfortunately, this was not the case. Rectal surgery was being done almost entirely by the general surgeons. None of them saw any great volume and regarded it as of rather minor importance. Therefore, they performed the routine operation which gave fairly good results and gave the matter no further investigation. Of the non-operative treatment they had little real knowledge. They saw only the cases where the results were bad. Basing their conclusions on these and upon the type of men employing the non-surgical method they condemned it. As they were also teaching proctology in the medical colleges they passed their opinions on to their medical students, who, of course, took the statement for its face value. Thus, without adequate investigation, this idea was spread through the whole profession.

However, time produces changes. An increasing number of reputable medical men began to limit their practice to proctology. Medical colleges, recognizing the need of more thorough instruction in this field, began to offer courses in rectal diseases. The courses offered were (and still are) inadequate, but they were an improvement. More thorough research was made in rectal diseases. Many old theories were exploded. Among other matters investigated was the non-surgical treatment of hemorrhoids. It was found to have real merit and in the past ten years has grown greatly in favor. This real increase in interest probably dates from a paper given by Dr. Terrell of Richmond in 1914, in which he advocated the use of quinine urea hydrochloride. Since that time it is safe to say that, insofar as the American Proctologic Society is concerned, at least 80 per cent of its members use it to a greater or less extent.

Briefly stated, just what is the principle of the non-operative methods? A hemorrhoid is in a general way the same as an angioma or nevus elsewhere in the body. It is like a sponge filled with water. When the blood is squeezed out of the plexus of veins which composes it there is very little tissue left. Thus anything which occludes or destroys

the blood vessels shrinks the hemorrhoid to almost nothing. Only a little ridge of scar tissue is left. This method of cure can be used only in the case of internal hemorrhoids. The cure can be produced by two non-operative procedures, which I will briefly outline.

The first is electrolysis. The direct current is employed. A dispersive pad is placed on the abdomen and then one or more needles connected with the opposite pole inserted into the hemorrhoid. Either the positive or negative pole may be used. From three to fifteen milliamperes of current is allowed to flow from five to thirty minutes. The pile turns a gray white color, at which point treatment is discontinued. One or two treatments suffice to cure each hemorrhoid. I have used this method in a number of cases but have practically discarded it for the injection method. My reason for this is that the injection method is much more rapid and in my experience has been less disagreeable to the patient.

Of the injection method there are two variations. The first I speak of only to condemn. That is the injection of strong solutions (usually carbolic acid) for the purpose of destroying the hemorrhoid and causing it to slough. I consider this a dangerous practice. It is the older method and the one from which most of the complications and deaths were reported. It is impossible to limit the extent of the destruction of tissue, and infection, abscess and secondary hemorrhage are complications which may occur. For these reasons I never employ it.

The other method consists of the injection of less strong solutions into the hemorrhoids. The purpose of these is to produce enough irritation so that the blood vessel is occluded by the resulting scar tissue, thus curing the hemorrhoid. I have tried various solutions and believe that it makes very little difference what solution is used, provided that it is just strong enough to produce the required reaction without producing a slough. A solution of 20 per cent carbolic acid is recommended by Morley and most of the older formulas contained this drug in from 5 to 50 per cent. To the phenol has been added fluid extract of ergot, olive oil, glycerine, witch hazel, creosote, zinc chloride, salicylic acid and many others, either alone or in combinations. These I think are entirely unnecessary, but were added to suit the whim of some individual who probably did not

know himself just what action they produced. The phenol is the active agent and is sufficient.

At the present time quinine urea hydrochloride in from 5 to 10 per cent solution is probably being used more extensively than any other solution. This was first advocated by Terrell of Richmond, Virginia, in 1913. This drug produces the desired result. It is practically non-toxic and, in my experience, less likely to cause pain than the phenol solutions. I have seen one patient who had an idiosyncrasy for quinine made quite ill by one injection and have had a few patients who complained of roaring in the ears. Otherwise, I have seen no complications caused by the drug itself. The technique of these injections is relatively simple. The internal hemorrhoid is brought into view through a slotted speculum. The surface is swabbed with alcohol and from .25 to 1 c.c. of solution injected deep into the center of the pile near its base. The number of hemorrhoids treated at one time and the interval between injections is governed by the reaction produced.

I have used this method of treatment in approximately 1,200 cases, charity and private. One patient had a severe reaction due to an idiosyncrasy to quinine. There have been several cases of superficial sloughing. This was caused by too much fluid being injected and too near the surface. In these, three were followed by secondary hemorrhage, but in each instance the patient, contrary to advice, allowed himself to become constipated. There have been no deaths and the end results have been uniformly good. From these cases and those reported by other men doing any considerable amount of rectal work, I cannot but feel that it is really less dangerous than the usual operative procedure and that the results are fully as good.

In conclusion then, what can be said concerning the non-surgical treatment?

1. It is an old method which even in the hands of incompetent men produced some good results.
2. In the past ten or fifteen years it has been adopted by the majority of men specializing in rectal diseases.
3. From reports of these men, the method in selected cases gives fully as good results as the usual operative procedure.
4. Conservatively speaking, it is at least no more dangerous than the operative procedure.
5. It does not confine the patient to bed or keep him from his ordinary occupation.
6. Many sufferers will submit to this method of treatment when they refuse operation.
7. By refusing to use this form of treatment where possible, we drive our patients into the hands of incompetent and unscrupulous quacks to the detriment of both the patients and our profession.

THE SCIENTIFIC AMERICAN ON ABRAMS' "ELECTRONIC REACTIONS"

In October, 1923, the Scientific American announced that it was undertaking an investigation of the "Electronic Reactions of Abrams" and electronic medicines in general. The Scientific American has published twelve papers and the last has now appeared. The result of the exhaustive investigation of the committee may be summed up: The electronic reactions of Abrams and electronic medicine in general is found utterly worthless. This is expressed a

little more in detail in the opening paragraph of the last article: "The so-called Electronic Reactions of Abrams do not exist—at least objectively. They are merely products of the Abrams practitioner's mind. These so-called reactions are without diagnostic value. And the Abrams oscilloclast, intended to restore the proper electronic conditions in the diseased or ailing body, is barren of real therapeutic value. The entire Abrams technique is not worthy of serious attention in any of its numerous variations. At best, it is all an illusion. At worst, it is a colossal fraud." —(*Journal A. M. A., Sept. 20, 1924, p. 939.*)

INDICATIONS FOR SURGERY IN DUODENAL ULCER*

VERNE S. CABOT, M.D.
Minneapolis

The diagnosis of duodenal ulcer having been established its treatment becomes the issue. A long controversy has been waged as to the proper ways and means of management; neither the medical nor the surgical exponents have been lacking in weighty evidence for their respective fields, nor in damaging array of statistics against their opponents. From this it is obvious that while both branches have had their successes and their failures a co-operative method of studying and caring for these cases should aid both internist and surgeon, with increased benefit to the sufferers.

There are various reasons for this divergency of opinions as to the treatment, because of the very nature of the disease. From the anatomical viewpoint the lesion is hidden and consequently cannot be actually verified except by surgery. Again the condition itself is often characterized by a tendency toward cyclic manifestations; that is, periods of exacerbation and remission, thereby often lending great weight to conjectures, even though wrongly placed. Again the symptomatology of duodenal ulcer can be in part or wholly simulated by pathological changes elsewhere. This paper acknowledges the presence of errors in diagnoses in our series of duodenal ulcer in spite of a routine method of investigation consisting of an exhaustive history, physical examinations, roentgen studies, laboratory studies and numerous subsequent therapeutic checkups.

Once a diagnosis has been reached with the methods available today the immediate management of the case presents. It is our observation that relatively few are surgical at the outset, surgical in the sense that the ulcer itself or its symptoms are demanding of immediate operative intervention. This does not apply to surgical treatment of co-existing or probably better, pre-existing lesions such as infections of tonsils, teeth, sinuses, pelvis, etc. Operative treatment of these should not be classified as surgery of the ulcer per se, though their proper handling may be indispensable in the medical management of the ulcer.

Further, it has been our observation over a period of ten years during which time approximately eleven hundred cases of duodenal ulcer have been studied, that the greater portion of the ulcers demanding surgery are those who have had little or no care either in the way of removal of these co-existing infective processes or in proper medical supervision; that is, the patients who are surgical are largely those who are chronic sufferers in whom the lesion has wrought marked or permanent changes in the digestive tract.

Accordingly we have placed the majority of all cases on medical management admitting that a variable number of these will become surgical because of various factors entering into the individual case which the internist alone cannot hope to cope with. In properly selected cases it has been fairly demonstrated that a carefully planned systematic medical regime over a sufficient period of time will give the desired results in a large percentage. By results is meant that the patient shows a response to medical care, by freedom from pain and discomfort, return to satisfactory weight level, a regaining of strength so that the patient may carry on his vocation, and lastly, absence of previous ulcer symptoms. These should be attained early in the management and be maintained indefinitely.

While duodenal ulcer is classified as a clinical entity one may also consider it one of the manifestations of an infective process, the ulcer producing the greater train of symptoms. While the etiology of duodenal ulcer is as yet unsettled, we feel that the clinical evidence leans toward the theory of infection and its resultant toxemias. Because of this and because of the otherwise betterment of the general health surgery may be called upon to aid in the removal of foci of infection, these blocking the management until eradicated. That infection may play a most important role is further evidenced by the periodicity of the exacerbation—a plausible explanation being the variance of resistance versus virulence.

The cases to be surgically treated will be those for whom such management was not deemed advisable at the time first seen and those who failed to obtain relief under careful medical direction. These cases will be found to align themselves into several main groups, namely:

1. Those suffering from obstruction to the food current, due to stenosis, cicatrices, adhesions, etc.
2. Those with, or attempting, perforation.

*Read before the Northern Minnesota Medical Association, Duluth, August, 1924.

3. Those with associated intra-abdominal lesions.
4. Those with repeated hemorrhages.
5. Those where a question of malignancy enters into consideration.
6. Those suffering repeated exacerbations despite thorough and complete medical management.
7. Those who for various reasons cannot or will not submit to a medical regime over a sufficient period of time.

A patient's working conditions or his economic status cannot in themselves be classed as reasons for considering surgery prior to a carefully planned management, although the patient's inability to co-operate may decide and offer but one solution, namely, operative intervention. Neither is a recurrence of previous ulcer symptomatology necessarily proof of medical inability to control the condition. It is not the number of breakdowns that alone determine for surgery, but the degree of intensity with which the patient and physician have carried on.

The marked tendency toward chronicity in duodenal ulcer in itself may be but a further manifestation of hidden or unlocated causative forces which if recognized and removed would ultimately favor a complete recovery. The pathologists inform us that healed ulcers of the duodenum are often seen. That nature needs but little aid—but this often and prolonged—is well shown by the immediate improvement seen in a majority of these cases as soon as management is instituted. Cases that do not show immediate response should be looked upon with suspicion as to the reliability of the diagnosis. If further studies reveal the presence of ulcer it is well to consider the possibility of associated lesions entering the picture.

The point so often heard that duodenal ulcer patients break down eventually regardless of medical efforts is, we believe, of no great argumentative value. Granted that a number do relapse, this point is no more applicable to duodenal ulcer than to many other clinical entities in which the relief of a train of symptoms is not necessarily proof of their inability to recur.

The consideration of these cases then who for various reasons do not respond medically should constitute the surgical aspect of duodenal ulcer. Surgery, while of undeniable benefit, and in fact the only salvation in some types of ulcer, should

be much as a court of last appeal, or better, as an adjunct to methods previously applied.

No mention has been made of those cases of duodenal ulcer in whom other pathological processes have developed to advanced stages, as for instance, duodenal ulcer complicated by diabetes, nephritis, marked cardiac or vascular disease, etc. The handling of these cases will of necessity depend upon the picture as presented by the individual patient.

The detailed technical phases of the various operative procedures will not be gone into at this time, however, a consideration of the pre- and post-operative periods are worthy of both the internist's and surgeon's attention. Too great emphasis cannot be placed on the preoperative preparation of these people. Especially is this true of the chronic sufferer who has had increasing obstruction with corresponding lowering of general health and often in addition concomitant lesions in other vital tissues. When first seen they are often markedly dehydrated, toxic, malnourished and in no way capable of withstanding the additional taxation involved by surgical intervention. Here is probably the greatest opportunity for actual co-operation of internist and surgeon. It is remarkable how responsive these otherwise poor surgical risks are to preoperative preparation consisting essentially of alleviation of pain and discomfort, absolute rest, re-establishment of balance of body fluids, etc., to the extent that in a short time one can feel safe in assuming their resistance has more nearly approached the normal, thereby lessening the operative hazards.

The question of the choice of anesthesia, while always one of great moment, is of special import in many of these subjects. In suitable cases, local anesthesia offers much to the patient's ultimate benefit; in fact, it may be the only method by which the necessary surgery can be safely attempted.

In considering the numerous types of operative procedure for relief of duodenal ulcer it will be found that all methods can be grouped under two main headings, namely:

1. Those in which the removal of the diseased area is the essential.
 2. Those in which increased gastric drainage or shunting of the food current is the primary object.
- From these two basic principles numerous modifications and combinations have evolved. It is

necessarily so in view of the manifold variations in the character of the lesion, as to size, location, extent of involvement of adjacent tissues, associated pathology in other organs, etc.

It is at once apparent that no one procedure will be applicable to all cases, the selection of the time and method of repair determining to a large extent one's successes.

The importance of the preoperative period has been briefly outlined. The operation passed, the postoperative care presents. This should be immediately instituted, the internist insisting on the same detailed supervision and this over a period of time comparable with that of an ulcer medically treated.

The purpose of medical education is to provide for the present and future citizens of the country the best medical care, service, and attention that is possible under the circumstances. We are not doing this today. And we are not likely to do this until we realize the faults in our present system of medical education.

Just now the story is making the rounds that there is a shortage of medical men. Nothing could be further from the truth. The fact is that the medical profession as a whole, and particularly of the cities, is greatly overcrowded. Seventy-five per cent of the medical men of Chicago could easily do twice as much work as they are actually doing, and should do twice as much and have twice their present incomes, if they are to get a fair return on the money invested in their education. The real difficulty is a faulty distribution as to location and the prevailing tendency of medical schools to turn out more and more specialists and fewer and fewer general practitioners. As a consequence of the above, the residents of some of our rural districts are in danger of soon not getting the kind of medical service which their ordinary ills require, for fully ninety per cent of human ills can be best treated by a well-trained general practitioner. My contention is that the medical schools of today, particularly the ultra-scientific medical schools, do not properly supply the demands of the times and that the education offered and the text-books used are extremely faulty. The medical schools must first realize their shortcomings, then deliberately make an effort to fulfill the function for which they are primarily created, namely, the education of general practitioners of medicine. The education of the specialists should be left to properly constituted post-graduate medical schools and hospitals. Every medical student should first of all be given the opportunity to become an efficient general practitioner, and then later, after having had five years or more of experience in the general practice of medicine, if he shows special fitness and a desire to become a specialist, the post-graduate schools and hospitals should offer the opportunity.—*E. H. Ochsner, M.D., Illinois Med. Jour., June, 1924.*

THE CHOICE OF METHOD IN BLOOD TRANSFUSION*

DONALD K. BACON, M.D.
St., Paul

Blood has, since time immemorial, aroused the interest of mankind. Certain savages believe, to this day, that by drinking the blood of a particularly courageous enemy they will be endowed with his virtues.

The idea of the intravascular introduction of the blood of another, while representing a much higher mental development, is still centuries old and antedates Harvey's discovery of the circulation. The first recorded attempt is probably that of the Jewish physician in attendance upon the last illness of Pope Innocent VIII in 1492.¹ He employed three small boys as donors, all of whom died and without benefit to the patient.

Transfusion between animals was actually accomplished in 1665.²

Little of a really constructive nature was done in this line for several centuries. With the stimulus to surgical progress offered by the work of Pasteur and Lister the subject again came into prominence and many were the methods employed when intravenous injection was found to be feasible. At this time premature clotting of the blood offered one of the greatest obstacles to the successful completion of the procedure. To avoid this it became popular to use defibrinated blood for injection. The excess of fibrin ferment present rendered the blood highly toxic in itself and when it is remembered that at that time blood groups were not dreamed of, we may well imagine that when disaster did not follow, results were at best indifferent. It must also be recalled that at this time the indications for transfusion were as vague as the technique was uncertain and it was advocated as a cure for any and every condition from simple anemia to senescence.

It has remained for the present century to see blood transfusion changed from a dream to a practical procedure of recognized clinical value and a few well recognized indications have supplanted the innumerable uses of an earlier day.

The entire feasibility of the procedure was first demonstrated through the advances in blood-vessel

*Read before the Ramsey County Medical Society, St. Paul, March 31, 1924.

surgery made by Murphy, Crile and Carrel, who were able to join the artery of one person to the vein of another so as to permit the unobstructed flow of blood from donor to recipient. The last link in the chain of safety was forged by Moss³ and Jansky, whose work on blood grouping placed the human race in four groups dependent upon serologic interaction between blood and corpuscles.

Flask prepared for transfusion by the citrate method

Fig. 1. Flask arranged for citrate transfusion. This contains 2 grams of sodium citrate dissolved in 50 c.c. of water. When mixed with 500 c.c. of blood the concentration is 0.36 per cent. The cork is loose on withdrawing blood. A pressure bulb is attached to the longer piece of glass tubing and used to force the blood into the recipient.

These studies showed the reason for the severe and sometimes fatal reactions which had occurred with such painful frequency in the early days of transfusion and pointed the way to safety.

Transfusion by blood-vessel suture left but one thing to be desired, namely, the ability to estimate accurately the amount of blood which passed over. This is a thing which is of great importance and impossible of performance unless the blood is taken momentarily into some measuring device before reinjection into the patient. Present-day methods have been devised primarily to overcome this difficulty and it is with them that this paper deals. They may be included under three general heads and while many modifications of unimportant details exist at different clinics, the list is increased only by sub-groups. Singularly enough, the three methods were reported in three successive years and one depending upon chemical alteration of the blood to prevent coagulation while the other two deal with unmodified blood.

The first of these is the so-called citrate method of Lewisohn,⁴ who made use of the fact that blood containing a small concentration of sodium citrate,

usually 0.2—0.25 per cent, does not clot. So far as the original purpose, namely, the maintenance of a fluid state in the blood, is concerned, the citrate method is above reproach, as it may stand for hours or even days without clotting. At this point, however, the desirability of the method ceases, as later investigations have shown that in it, clinical value is sacrificed to convenience. After the method first came into use, reports came from all sides of so-called "reactions" which appeared within the following twenty-four hours. These consisted of a rise of temperature, with or without a chill, and evidence of hemolysis such as hemoglobinuria and a transient yellowish pigmentation of the skin and sclerae. The more severe reactions may lead to severe muscular pains, dyspnea and even death, while the milder grades have but a few hours of discomfort. These reactions occur between individuals with perfectly matched and grouped bloods and the secret evidently lies in the fact that such a complex and delicate physiologic product as blood is altered not only in its physical state but also in its biologic properties by the chemical treatment. Among users of the citrate method reports vary from 25 per cent to as high as 60 per cent of reactions. In a few instances

UNGER APPARATUS FOR WHOLE BLOOD TRANSFUSION

Fig. 2

such easily remedied accessories as new tubing and stale distilled water have been blamed for the reactions, but the fact remains that they are not eliminated when freshly distilled water and thoroughly seasoned tubing have been employed.

Unger⁵ has undertaken by a rather elaborate series of experiments to compare the qualities of citrated blood and the blood of animals and persons who have been treated with citrate transfusion

with whole unaltered blood. He has made some very significant observations which should be carefully weighed in the choice of a method for transfusion. He finds:

1. The addition of sodium citrate to the blood causes an increased fragility of the red blood cells. This tends to make the results of the transfusion short lived and shortens the usefulness of the transfused cells as oxygen carrier. Where the tendency already exists as in pernicious anemia it cannot but be inferior to one of the methods employing unaltered blood.

Fig. 3

2. It destroys the complement of the blood, as it also destroys the opsonins, thus rendering the method of inferior value where it is desired to combat sepsis or fortify the resistance of the individual to infection.
3. Phagocytosis is inhibited, which again reduces the value in the treatment of infection.

The work of Neuhof and Hirshfeld⁶ shows that citrate transfusions may have some place in the treatment of hemorrhage. These workers found that the injection of sodium citrate alone, either intravenously or intramuscularly, into a patient resulted in a marked reduction in clotting time. This phenomenon is more noticeable as the amount injected increases up to the point of toxicity, where there is a reversal of the process and the blood becomes incoagulable. They found that a clotting

time of ten minutes might be reduced to approximately two minutes by such measures. This procedure proved to be of value in all pathologic increases of the clotting time with the exception of those diseases characterized by a deficiency of blood platelets such as hemophilia and purpura. Good results were obtained in jaundice. With citrated blood a stage of toxification has been reached so that it does not clot. However, when it has been diluted by the entire mass of blood in the circulatory system the concentration is reduced to that point where the coagulation time is shortened.

To give an impartial verdict on the citrate method: It is easily and simply carried out, undoubtedly has value where transfusion is indicated, but has certain biologic after-effects which render it distinctly inferior to either of the whole-blood methods.

The methods employed in transfusion of unaltered blood rely upon rapidity and gentleness of manipulation with intermediate containers whose surfaces have been coated with non-irritating compounds to delay the inception of coagulation.

Fig. 4

The first of these is the so-called paraffin tube method which was brought out by Kimpton and Brown in 1913. They use a large glass container which has a small opening, closing with a cork at

the top, a side arm and a rather tortuous outlet at the lower end. This is coated on the inside with melted paraffin, which is allowed to cool, preventing mechanical irritation of the contained blood. The tube since devised by Vincent has a straighter, more easily cleaned outlet, and probably makes for greater efficiency. In carrying out a transfusion by this method, a few cubic centimeters of

by means of a cautery bulb attached to the side-arm. As the last of the blood leaves the tube it must be rapidly withdrawn from the vein and the vein closed, otherwise serious air embolism might result. When 600 to 900 c.c. have been transferred, by the use of two or three tubes, the transfusion is complete and the veins may be ligated and the skin closed.

Objections to the paraffin tube method have been based on several grounds which may be worthy of discussion:

1. Certain writers have objected to the fact that a skin incision is necessary as smacking too much of a surgical operation. The small skin incision necessary is scarcely to be dignified by that name and where the method is employed as a preoperative and postoperative measure at the time of more formidable surgical measures, it is probably the most rapid and efficient means of transfusion.
2. It has been objected that the ligation of one of the veins of the forearm is wrong when other methods might obviate that necessity. Again a small matter, in the author's opinion, for the average surgical transfusion, which seldom occurs to a person more than once in a lifetime. The superficial veins of the forearm are sufficiently numerous that the loss of one of them need cause no concern. With medical cases such as pernicious anemia, where repeated transfusions are needed, it is a different matter and will be mentioned later.
3. It has been claimed that proper paraffin coating of the tubes is extremely difficult. In the author's experience it is quite simple to secure a complete and smooth coating if both tube and paraffin are well heated. The one point where the greatest care is necessary is to prevent collection and cooling of small droplets in the outlet or sidearm, as either necessitates that the tube be recoated.

The last method to be described is that of Unger, who has devised a mechanical contrivance for securing the desired result. This consists of a small round box-like affair with four outlets to each of which is attached a piece of rubber tubing. Two of these on opposite sides have needles entering the vein of the donor and the recipient, the

METHOD OF TYING OUTLET POINT INTO VEIN TO PREVENT LEAKAGE

Fig. 5

novocaine solution are injected under the skin overlying one of the veins of the forearm and a short incision made. The vein is freed and two strands of suture material passed about it, one proximally and one distally. In the donor the vein is tied off proximally and in the recipient, distally. The other legature is not tied until the transfusion is completed, but the ends are grasped by a hemostat, which is left attached. Traction on this ligature serves to stop all outflow of blood. A three-cornered incision is made in the donor's vein and the outlet of the tube inserted, point directed distally. A blood-pressure cuff about the upper arm is inflated to 50 mm. of mercury and held at this point until the tube is filled. Filling proceeds rapidly and can be aided by rhythmic contraction and relaxation of the muscles of the donor's forearm. This simulates the action of a pump. When filling is completed, the sidearm is covered by the thumb of the hand holding the tube and it is carried to the recipient, whose vein is similarly prepared, an assistant meanwhile making traction on the untied ligature about the donor's vein to prevent bleeding. The outlet of the tube is inserted into the recipient's vein, point directed proximally. The blood can rapidly be pumped into the vein

third is connected to a 50 c.c. syringe, which is well lubricated with paraffin oil, and the fourth is attached to a graduated funnel of saline. The cover fills the box, is grooved on opposite sides and rotates through ninety degrees. When the transfusion is started the cover is turned to the point where the syringe can be filled from the donor's vein while saline runs slowly into the recipient, keeping the needle and tubing free from blood, so that no clotting may obstruct the lumen. When the syringe is filled the cover is rotated to the point where the blood can be forced out, this time into the recipient, while the saline flows into the donor and keeps the needle and the tubing clean. When the syringe is empty the cover is reversed and more blood drawn. This procedure is repeated a sufficient number of times to transfer the desired quantity of blood.

The Unger method is a highly practical means of transfusion and gives excellent results where repeated transfusions are necessary, as the same vein may be used time and again. The weak points of the method are several and should be mentioned. First, the method is slower than the paraffin tube method and where speed is a factor in single transfusions it must be discarded. Second, there is a greater risk of clot formation in the relatively intricate mechanism than in either of the other methods. Third, the successful completion of a transfusion requires that two needles be kept in two separate veins and in working condition at the same time, sometimes a difficult matter with a single needle and vein where the patient is apprehensive and restless, or where the veins are small and difficult to find.

As contrasted with the citrate method, the whole blood methods offer certain quite definite advantages insofar as the results obtained are concerned. Post-transfusional reactions have been mentioned as one of the serious drawbacks of the citrate method, while following either of the whole blood methods they are a rarity. In an experience of some 250 paraffin tube transfusions and perhaps twenty by the Unger method, the author does not recall a single instance of transfusion between patients with compatible bloods where any after-effect which could be dignified by the name of reaction has been noted. Rarely, if ever, does the temperature rise above 100 degrees as a result. All writers report a low percentage of reactions, some less than one per cent.

This must not be taken to mean that the after-effects will be negligible if a donor of the wrong group is used, for under such circumstances the response will be swift and unmistakable. In the few instances which it has been the author's ill-fortune to witness, the patient has been trembling, dyspneic and complaining of precordial pain by the time 150 c.c. of blood had been received. If the transfusion is immediately stopped on the appearance of such symptoms no greater harm results than an unsuccessful transfusion and a case of hemolytic jaundice, but if the warning is disregarded death may result.

When sepsis is the indication to be met, the method employed should be one of those employing the unmodified blood, as by this means immune bodies may be transferred intact and unaltered by the paralyzing effect of the sodium citrate. Similarly in the anemias, particularly of the primary variety, the use of sodium citrate increases the fragility and shortens the lives of the already too friable red cells and it should be discarded for a method with fewer drawbacks. In the acute anemia of hemorrhage, where a shortening of the clotting time is desired, the use of citrate transfusion seems most justifiable, but objections may be offered to its use in even this limited field, since striking results follow the giving of whole blood.

Recent studies have demonstrated that infants may be transfused by the injection of blood into the peritoneal cavity, whence it is absorbed into the circulatory system, but the author must plead lack of experience in this procedure and omit it from discussion.

CONCLUSIONS

1. The sodium citrate method carries with it heavy liabilities and should be discarded insofar as possible.
2. Transfusion as an aid to surgical measures where more than one transfusion is rarely necessary can best be done by the paraffin tube method.
3. In conditions requiring repeated transfusions, namely, the anemias and other medical conditions, the Unger method is preferable to all others.

"The type of practice of a decade ago permitted much symptomatic treatment. Diseases were allowed to run their course. The doctor was in a way the protector and nurse and comforter of the patient. The marked advances made in preventive medicine make it inevitable that the medical student of today and tomorrow must study the normal more than the abnormal and that he must be familiar with the incipient stages of all disease processes and recognize the first perversions from normal physiology and the first signs of abnormal pathology. The old easy practice of medicine has gone never to return. Great skill in the recognition of the early stages of disease means pre-eminence in medicine in the future. It is unfortunate that these periods of the beginning of disease are most susceptible to quackery and to deceit. We are all familiar with the phrase "threatened with pneumonia" or "threatened with disease." It is also inevitable that the very fact that we are able to relieve patients in the early stages of their diseases will in a way interfere with their interpretation of our success.

"The man who has an early operation for appendicitis often has such an easy time following his operation and during his convalescence that he sometimes wonders whether the operation was necessary. There is still great respect for the doctor who lets the patient go so far that he is only able to save him by the most energetic and persistent attention. This need not interfere with sound medicine and an increase in the respect on the part of the public for medicine. There is a gradually rising level of intelligence among our people and more and more of them are getting some biological understanding of life."—Extract from address by Dr. Ray Lyman Wilbur, President-elect of the A. M. A., at annual meeting of the California State Medical Society, May 16, 1922.

POST-OPERATIVE MANAGEMENT FOLLOWING GASTRIC OPERATIONS *

THOMAS O. YOUNG, M.D.

Duluth, Minn.

and

L. HAYNES FOWLER, M.D.

Minneapolis

Until recent years operations upon the stomach for ulcer of the stomach and duodenum and for gastric carcinoma have not received the attention they merit from the standpoint of postoperative treatment. The early recognition of the different types of complications and the institution of prompt and efficient treatment may mean not only the saving of a life, but may have a very definite bearing upon the success of the operation from the standpoint of a cure. In normal post-operative reactions the proper dietary treatment may prevent serious post-operative complications and is also a very important factor, from the standpoint of the ultimate success of the operation, in procuring permanent relief of the condition.

Operations upon the stomach naturally fall into two divisions from the standpoint of post-operative complications.

1. Gastro-enterostomies for duodenal or gastric ulcer where no further surgery on the stomach is done. Knife excision of duodenal ulcer with minor type of pyloroplasty such as a Mikulicz.

2. Gastric resections including Billroth No. I, Billroth No. II, anterior Polya, posterior Polya, and sleeve resection as well as Finney type pyloroplasties and gastro-enterostomies where a knife or cautery excision of a gastric ulcer is performed.

Complications following the first group, which comprises chiefly gastro-enterostomies, may be divided roughly into early and late complications.

Among the early complications hemorrhage⁶ is probably the most important. Evidence² of hemorrhage may be seen at any time within the first forty-eight hours. The vomiting of bright red blood in any appreciable amounts should be considered very seriously. Vomiting of small amounts within a few hours of the operation does not mean much as it is usually due to residual blood left in the stomach following the operation or to a very slow oozing along the suture line. Clotting usual-

*Read by request before the St. Louis County Medical Society, Duluth, September 8, 1924.

ly takes place within a short time in these cases. The onset of a real hemorrhage is usually the result of suddenly increased arterial or venous pressure due to straining from vomiting or coughing. In these cases the stomach is unable to empty through the pylorus and gastro-enterostomy opening as fast as it fills with blood, with the result that a reflex vomiting is set up. Vomiting attacks may occur regularly from a few minutes to an hour apart. The blood is usually bright red and may be accompanied by large clots. Morphine hypodermically in doses large enough to produce absolute quiet is indicated. Ice bags should be put to the epigastrium. Repeated gastric lavage with water at a temperature of 120 F. will usually control the bleeding. This may be performed as early as twelve hours post-operative without danger. In case the bleeding has been extensive enough to materially reduce the blood volume, hypodermoclysis of normal saline, intravenous saline injections, and blood transfusions are indicated. The use of the various intravenous medications for the purpose of decreasing the coagulation time of the blood and promoting clot formation may be useful and should be tried along with other methods.

Profound operative and post-operative surgical shock following operations upon the stomach is of infrequent occurrence in the hands of experienced surgeons. It is usually due to prolonged operation with marked surgical trauma and is more frequent in its occurrence in the debilitated and dehydrated type of case seen so often with gastric carcinoma. Its occurrence following simple gastro-enterostomy is very rare. In cases with marked obstruction at the outlet due to contracture from scar tissue formation and its resultant dehydration and debilitation the incidence may be more frequent. However, it must be remembered that post-operative surgical shock and other complications can be practically eliminated by proper pre-operative measures in preparing the patient. When surgical shock occurs it is usually present directly after operation. It may be mild and transient or it may present more marked and serious symptoms. The symptoms are identical with surgical shock seen in other conditions. The patient presents the typical picture of a rapid, feeble pulse, slow, shallow respirations, marked perspiration, and a cold clammy feeling of the skin which is of a dead, whitish color. The milder cases usually respond very readily to the ordinary measures, such as ele-

vation of the foot of the bed, external heat to the body in the form of numerous hot water bags, and the administration of a shock enema containing black coffee and whiskey. If the patient does not respond to this treatment within an hour the condition should be considered more serious. Transfusion, and intravenous and subcutaneous saline are indicated if there has been any appreciable bleeding. An immediate transfusion of 500 c.c. of blood will often be found to tide a patient over this very critical point, when all other measures may fail. This is indicated whether or not there has been any extensive loss of blood. Caffeine hypodermically as a stimulant is also useful.

Brown⁴ advocates feeding the patient peptonized milk while on the operating table as a preventative of surgical shock. He inserts a soft rubber catheter into the stomach just before it is entirely closed, passes it down into the lower jejunum; introduces the peptonized milk; withdraws the catheter and completes the operation.

Dilatation⁷ of the stomach occurs occasionally following gastric operations. Of ninety-two post-operative cases reported by Borchgrevink,³ six occurred after stomach operations, while thirty followed operations on the female genital organs. The most common time of onset is within the first forty-eight hours post-operative. Reardan¹¹ reports two cases of dilatation during the time of operation and emphasizes this phase of the subject.

There have been many theories⁹ as to the cause of this condition of which two are the most important. First, the theory of duodenal occlusion produced by the upper border of the mesentery with its contained superior mesenteric vessels. Second, that of a paralysis of the muscular wall of the stomach, possibly due to swelling and edema around the site of the operation. This results in temporary obstruction to the extent that anti-peristalsis is not sufficient to cause it to empty itself. The latter theory at the present time is the most commonly accepted explanation of acute post-operative gastric dilatation. Because the patient is not getting fluids in any form by mouth is not sufficient reason for neglecting to consider the possibility of dilated stomach as the cause of the trouble if the patient is not doing well. Oozing around the site of the operation and the normal secretion of the mucous membrane is sufficient to cause this condition if the stomach is not emptying itself properly.

Vomiting is usually a prominent symptom, and is an overflow, regurgitant type, large quantities of bile stained material being expelled. Pain varies from a mild discomfort to severe epigastric distress. If the condition exists for any period of time, the patient will often show signs of collapse, with a rapid thready pulse, the skin cold and moist and respirations rapid and shallow. Due to the loss of large amounts of fluid by vomiting, there is an extreme thirst and a scanty excretion of urine. Examination of the abdomen with the dressing off will usually reveal the trouble. Dullness over the stomach area with distention especially of the left abdomen should be sufficient reason for the use of the stomach tube. The above symptoms, with the escape of a large quantity of fluid and gas, and the relief of the distention on passage of the stomach tube, will establish the diagnosis.

The treatment consists first, of early and efficient gastric lavage, and second of postural treatment. Lavage should be performed on the first suggestion of any of the above symptoms, and repeated every six hours or frequently enough to keep the stomach empty. The statement attributed to a famous surgeon, that a young man entering the practice of surgery should discard his stethoscope and replace it with a stomach tube about his neck, while not to be taken literally, nevertheless serves to emphasize its importance in general surgery. The value of its proper use is even more marked as applied to gastric surgery. Oschner¹⁰ now has a standing order for his patients that "the moment a patient vomits or is nauseated or complains of gas pressure, gastric lavage with water at a temperature of 105 F. is performed immediately." In a considerable experience in gastric surgery the authors have never seen harmful results from the use of the stomach tube. Schwartz¹² reports one case of perforation of a chronic gastric ulcer caused by trauma from a stomach tube, but such cases are so rare that they can be disregarded when we consider the great benefit derived from the proper use of this simple instrument.

Secondly, if possible the patient should be placed in the knee-chest position, with the hips elevated higher than the head. Theoretically this will relieve the pressure from the intestines and mesentery on the duodenum.

No operative treatment for gastric dilatation has been found to be successful.

Some form of gastric obstruction is probably the

most frequent and important complication of gastric surgery. It may be temporary or permanent, mechanical or inflammatory, partial or complete.

The causes are incorrect diet, inflammatory swelling and edema around the stoma, mechanical twists or kinks in the loops, too small an opening, constriction due to scar tissue, misplacement of a gastro-enterostomy, peritonitic ileus and anterior gastro-enterostomy. It should be understood that the latter is only done in cases of carcinoma, with complete or almost complete obstruction, as a purely palliative measure, where it is impossible to do a posterior gastro-enterostomy. The importance of a proper dietary regime as a prophylactic measure against obstruction cannot be too strongly emphasized. This will be discussed in more detail later.

The first symptoms of obstruction may be noticed any time after the first twenty-four hours. The most frequent time of onset, however, is from the seventh to the twelfth day post-operative. The patient frequently will not complain, but on close questioning will admit that he does not feel as well as on the previous day, or "that he has a full feeling" after eating. Very often hiccough will be the first symptom of gastric retention. We have never seen a patient with hiccough after a gastric operation fail to reveal retention.

If these milder and apparently insignificant signs are not noted or regarded as sufficient evidence for the use of the stomach tube, the unmistakable sign of vomiting will soon ensue, and unless prompt and efficient treatment is instituted, the patient will lose ground rapidly.

The treatment should be directed along two lines, dietary and lavage. First, gastric lavage should be done at least twice a day. If this does not keep the stomach empty, or there is retention of over 500 c.c., it should be performed every six hours. Secondly, everything should be taken away by mouth for twenty-four hours, and a fluid intake of 2,000 to 3,000 c.c. a day maintained by proctoclysis of tap water, or 2 per cent soda bicarbonate and 5 per cent glucose solutions. If proctoclysis is not retained, normal saline may be given by hypodermoclysis. After twenty-four hours of starvation, fluids may be started, using tepid water, one ounce an hour by mouth for twelve hours. If retained well, small amounts of tea, broth, and gruel may be added gradually increasing until a regular post-operative retention diet is retained. During this

period it is very important to keep a careful record of the amount of fluid which is getting past the obstructed point in the bowel. The amount of material vomited and the amount withdrawn by stomach tube should be measured and subtracted from the total fluid intake. The difference should be supplemented by sufficient fluids per rectum or subcutaneously to bring the fluids up to the required amount. The retention diet should be entirely liquid with a high percentage of absorbable foods of a high caloric value, and should be given in small amounts at frequent intervals. The following is an example of the type of diet which may be used in these cases:

- 6 A. M. 1 glass hot milk (one-half cream).
- 8 A. M. Cereal gruel (made with milk) sugar.
- 10 A. M. 1 glass malted milk (one-half cream).
- 12 noon 6 oz. cream soup (one-half cream and one-half milk used).
Cocoa or Kaffee hag—cream—sugar; soft custard or jello with whipped cream; sherbet.
- 2 P. M. 1 glass buttermilk.
- 4 P. M. Egg-nog (one-half cream).
- 6 P. M. Cereal gruel—sugar, cocoa or Kaffee hag—cream and sugar, ice cream.
- 8 P. M. 1 glass hot milk (one-half cream).

This will total approximately 2,796 calories, when cocoa is served for one meal and Kaffee hag for two.

Dixon⁵ has recently shown that these cases of upper intestinal obstruction have not only characteristic clinical signs, but also constant chemical changes in the blood. These consist of a lowering of the plasma chlorides and increase of the blood urea and carbon dioxide combining power of the blood. The administration of sodium chloride subcutaneously, intravenously or by proctoclysis brings the blood findings to normal, reduces the associated toxemia and lowers the risk of a secondary operation.

A great majority of obstructive cases will be relieved by the above regime if it is persisted in. This type is usually due to an inflammatory thickening of the stoma, or to too rapid an increase in the diet, putting large quantities of food in a stomach whose innervation and normal peristalsis have been interfered with, and whose emptying power as a result is temporarily disabled.

A few cases do not respond to lavage and dietary restrictions, and these present a most serious problem. Whether to perform a secondary operation, and if so, when, and how much to do are questions of vital importance. At this stage, a patient has

been partially or totally obstructed from five to fourteen days or more. He has lost weight and strength; he is undernourished and dehydrated. The blood chlorides are low, and the carbon dioxide high. Here no general rules obtain. Each patient is a law unto himself according to the judgment and experience of the individual surgeon. One statement, however, will apply to all cases; namely, do not do too much surgery. More than one patient has lost his life because of too much surgery at this critical period.

If the condition of the patient will warrant it, the abdomen may be opened under local anesthesia, and the site of the previous operation examined for the cause of the obstruction. As previously stated this may be found to be due to too small a stoma, malposition of a gastro-enterostomy; constriction of the opening due to edema or scar tissue; mechanical twists or kinks in the proximal or distal loop, or too long a proximal loop. The relief of these conditions will again depend upon the ingenuity of the surgeon. In many malfunctioning gastro-enterostomies, a simple entero-anastomosis between the proximal and distal loop will relieve the symptoms; or an attempt may be made to enlarge the stoma. In a few cases¹ the gastro-enterostomy will have to be taken down and some form of gastro-duodenostomy performed.

The condition of many of these obstructive cases, however, will not warrant the trauma and shock incident to exploring the site of the previous operation. They are starved and dehydrated. In such a case, a jejunostomy of the C. H. Mayo type done under local anesthesia and without exploring is indeed a life saving procedure. Twelve hours after such an operation, small amounts of liquid nourishment (one ounce an hour) may be given through the enterostomy tube, this may be gradually increased until the patient is in condition to stand more extensive operative procedures, or until the obstruction is relieved.

Post-operative gastric tetany does not occur frequently. Its occurrence is always associated with gastric obstruction as described above, and is definitely dependent upon the duration and degree of obstruction. If obstructive symptoms are present, recognized early, and properly treated gastric tetany will not occur. However, in some cases the symptoms will not be sufficient to cause apprehension and the danger signals disregarded until the tetany develops. The symptoms are characteristic,

the attacks usually being preceded by drowsiness. The pulse is weak and the respirations shallow. Convulsions occur in the majority of cases and are characterized by clonic muscular contractions. They are usually followed by a comatose or semi-comatose condition. The position d'accouchiere of the hands with the thumbs slightly turned in is practically always found. The blood findings of low plasma chlorides and high carbon dioxide combining power will verify the diagnosis. Treatment consists in first relieving the attack. This may be done best by the simple administration of sodium chloride in sufficient quantities to bring the blood chlorides to normal. It may be given either subcutaneously, intravenously or by rectum or by some combination of the three. This treatment will afford complete and almost immediate relief. Further therapy should then be directed against the obstruction as described above, always bearing in mind the necessity of keeping the chlorides as near normal as possible to prevent recurrence of the tetany.

Peritonitis following gastric operations may be divided into two groups from the causative standpoint:

1. Peritonitis with no apparent contamination at operation and no evidence of leakage or perforation of the suture line.

2. Peritonitis due to leakage of the suture line. In most cases it is difficult to differentiate between the two. However, a patient who has had a normal convalescence, that suddenly develops a sharp piercing pain in the epigastrium with symptoms of shock can be definitely classed as due to sudden leakage through the line of suture.

The authors have seen two cases, in which a Murphy button entero-anastomosis between the two loops of a gastro-enterostomy was performed, develop a sudden pain in the lower abdomen and go into shock. Autopsy revealed a "blowing out" of the Murphy button anastomosis with general peritonitis. These occurred on the ninth and tenth days post-operative following an apparently normal convalescence.

If the onset of the symptoms is gradual and within a few days after operation it may or may not be due to leakage. If the symptoms are definite enough to make the diagnosis of perforation of the suture line fairly sure, operative interference is the treatment of choice. If operation is not resorted to, medical treatment with heavy doses of

morphine, ice bags to abdomen in the early stages, nothing by mouth and hypodermoclysis seems to produce as good or better results than any other treatment. At best the mortality will naturally be very high in these cases.

Even more important than the treatment of complications is the treatment of the much larger group of uncomplicated cases. This treatment should be directed toward keeping the fluid intake at a normal level and proper dietary measures. Strict adherence⁸ to a definite conservative post-operative regime will cause a much greater percentage of cases to be classed as uneventful convalescents. In the first group nothing should be given by mouth the first forty-eight hours. Proctoclysis of tap water, glucose and sodium bicarbonate, or normal saline. Hypodermoclysis may be used if proctoclysis is not well tolerated. The fluid intake should be maintained at approximately 2,000 to 2,500 c.c. per twenty-four hours. If the patient is doing well the third day he may be started on one ounce of water by mouth every hour. This should be supplemented by proctoclysis or hypodermoclysis to attain the required fluid intake. The fourth day very weak, bland, and nourishing liquids such as broth, albumen water, and tea may be substituted for the water. The fluid intake by mouth may be increased to two ounces every hour. The fifth day post-operative it is usually possible and advisable to start the patient on very soft food such as junket, oatmeal or barley jelly. This should be limited to two ounces at a feeding. If the patient is not disturbed by this and desires it, it may be given every three hours. The sixth day junket, oatmeal or barley jelly with parboiled milk containing sodium citrate may be used alternately every two to three hours. Two to four ounces at a feeding may be used if well borne; water, broth or tea in small amounts may be taken between feedings. If there is any distress from the feedings they should be discontinued and the regime of the third or fourth day used. The seventh and eighth days should be continued as the sixth, feeding every two to three hours, alternating junket with rich milk containing 15 grams of sodium bicarbonate or 1.5 ounces of lime water. Simple custard lightly cooked, oatmeal jelly, blanc mange or a fresh soft boiled egg may be used. The feedings should be about three hours apart, the quantity of food each feeding may be four to five ounces. It is important that the patient should not be disturbed

while resting. Rather forego one feeding than that the patient be aroused for this purpose.

The diet after the first week may be considerably increased but should still be very bland and non-irritating and given in relatively small, frequent feedings.

Breakfast

Four to six ounces of well cooked cream of wheat, strained oatmeal or farina, one egg, soft boiled or poached. One piece of stale bread toast or zweibach, one cup of hot water and cream.

10 A. M.

Two-thirds of a glass of rich milk with one ounce of lime water or 15 grains of sodium bicarbonate.

Lunch

Serving of cream soup, pea, bean or asparagus or puree of potato; choice of chicken or meat jelly without the meat. Small amount of baked or mashed potatoes. Sweet apple sauce or apple butter served warm. Bread and butter. Hot water and cream.

4 P. M.

Two-thirds of glass of rich milk with one ounce of lime water.

Dinner

The same as at lunch excepting no soup. Substitutes or additions such as custards, gelatine, jello and simple pudding may be made. Hot water and cream flavored with tea.

8:30 P. M.

Milk toast or hot milk with soda or lime water.

It is very important to give no meat of any kind until after the tenth day and in most cases it is best to give very little for a period of three months. A case which is otherwise doing very well may be upset and obstructive vomiting started by the use of meat. This general outline will serve very well in the majority of cases. However, each case is somewhat of a problem in itself and should be handled as such. At the slightest indication that the diet is not being well tolerated it should be stopped immediately. In some cases it may be necessary to discontinue everything by mouth for a day or two and then return to the beginning of the diet schedule and gradually work up again. Others may be simply put back a few days in the diet schedule.

Complications following the second group are similar in most respects to complications following the gastro-enterostomy group. It will be remembered that the second group includes gastric resections, Finney type pyloroplasties and gastro-enterostomies where a knife or cautery excision of a gastric ulcer is performed. The reactions following this group, as would be expected, are usually more severe, the convalescence is more protracted and the mortality definitely increased. It is un-

necessary to consider the symptoms and treatment of the various complications as this has been covered in a consideration of the first group. However, a few points of divergence are worthy of mention. Hemorrhage occurs most frequently following this group. This can be accounted for by the much larger scope of the operation with the ligation of the blood supply over a larger area. Surgical shock occurs more frequently for the same reason and because of the additional time necessary for the operation. Dilated stomach occurs less frequently in resections of the stomach. If the anastomosis is large enough and made on the dependent portion of the stomach it is practically negligible. In Finney type pyloroplasties its occurrence is more frequent though not to any marked degree. However, the convalescence following this operation is as a rule definitely protracted and long drawn out. There may be no definite post-operative complication but just a tendency not to improve as fast as following most gastric operations. This can be accounted for by the fact that the pylorus which has been enlarged is still not as large as an ordinary gastro-enterostomy. The size is materially reduced the first few days after operation by the swelling and edema practically always present until normal circulation has been re-established and healing well started. This constitutes a partial obstruction which may give signs and symptoms of obstruction, retention and tetany if not apprehended. Complete obstruction and tetany following gastric resection is very rare, one case was seen with a fatal termination. This case was an anterior polya. The patient became very ill with obstructive symptoms and died within a few hours before tetanic symptoms developed. Post mortem examination revealed intense edema of the anastomosis with gangrene of a small portion of the anterior wall of the stomach due to insufficient blood supply. Temporary partial obstruction is seen fairly frequently following gastric resections, but is practically always relieved by the prompt use of the stomach tube and dietary restrictions as previously described. Peritonitis and perforation of the suture line has a somewhat higher incidence in this group. The symptoms and treatment of these conditions may be considered essentially the same as in the gastro-enterostomy group. The possibility of a fatal outcome if complications do occur, however, is definitely increased because of the greater severity of the operation,

and greater duration of the anesthetic with consequent increased lowering of the patient's resistance.

The routine regime as established and followed in all cases in the post-operative treatment of this group consists mainly in strict adherence to a definitely restricted diet. Here again the importance of carefully following such an outline cannot be emphasized too strongly. In any considerable group of cases there will be exceptions to the general rule, however. In these cases, where the diet is not well tolerated, it should be restricted even more, occasionally to the point of giving nothing by mouth for several days. Individual judgment combined with the findings of the stomach tube are the most important factors in determining what the stomach will tolerate.

The patient should have nothing by mouth the first seventy-two hours following this group of operations. Fluid intake of 2,000 to 2,500 c.c. each day is maintained as described above. The fourth day one ounce of tepid water may be given every hour unless contra-indicated. The fifth day two ounces every hour of broth, weak tea, albumen water or grape juice may be substituted for the water. Soft food may be started on the sixth day if the patient's convalescence has been normal this far. Two ounces of junket, oatmeal jelly, buttermilk, barley water or lime water may be given every two hours. One or two feedings may be given at night if the patient awakens. The seventh day blanc mange, custard or gelatine may be added. The amount should still be limited to two ounces every hour. Two ounces of water or tea may be given on the alternate hour.

Starting on the eighth day small meals may be given. The diet from this point is essentially the same as in the first group with the difference that the whole regime is one day later.

No meat should be given until after the twelfth day post-operative. The patient should be advised to eat slowly and masticate thoroughly. Sugar and pepper should be avoided and very little salt should be used. An hour's rest lying down after each meal is advisable. Cleanliness of the teeth and a daily bowel movement should be observed.

This takes the average patient to the point where he is discharged from the hospital. Here trouble may begin if he is not cautioned especially in regard to further restriction and care in his diet. He feels good and his natural tendency is to over

eat and enjoy a good meal as a change from the hospital diet. A very safe rule to follow is to tell him to eat about the same things he was getting at the hospital at the time of his discharge and to eat them in small amounts.

When the patient is ready to be discharged from the surgeon's care it is necessary to give him definite instructions regarding what and how much he can eat. It should be explained, according to the type of operation he has had done, that his diet in general should be selected from foods that do not cause mechanical, chemical, or thermal irritation of the stomach or that his meals must be small and frequent in order to give a stomach which has been greatly reduced in size a chance to compensate.

A glass of fresh or boiled milk to which a tablespoonful of lime water has been added at 10 A. M., 4 P. M. and bedtime is advisable. After the third month it is usually possible for the patient to gradually increase his diet up to normal. If at any time he encounters trouble he should return immediately to the smaller meals at frequent intervals. Milk taken with half cream throughout the convalescent period is good practice and an excellent weight builder. Caution as to general hygiene, such as care of the mouth, daily bowel movements, daily exercise and rest after meals is advisable.

SUMMARY

Immediate recognition and treatment of post-operative complications is essential and definitely shortens the convalescent period. A post-operative regime of a restricted diet greatly lessens the chance for complications and shortens the period between the time of the operation and the time the patient considers himself completely well.

The science and art of medicine have reached a degree of perfection so that what we need today even more than further scientific discoveries is to educate the lay public as to what medical men are actually doing for the welfare of the whole, in order that there may be better understanding and closer co-operation between the public and the medical profession. This information cannot be conveyed to the laity and this co-operation cannot be secured until the rank and file of the medical profession themselves are better informed along lines of medical economics. And we must first of all look to the medical editors of America to convey this information to the practitioners of medicine in order that they may then pass it on to the public. This gives the medical editors a wonderful opportunity to which I feel sure they will rise when they once see the importance of it. The thing to do is not to give less attention to the scientific fundamentals but to cut out many of the frills and foibles in diagnosis and treatment with which medical journals are now cluttered up. If we would pay less attention to the newer refinements in diagnosis, which often confuse rather than clarify, and to new operations which only too often complicate rather than simplify, both of which are usually discarded after a short time, and both of which I am sorry to say are only too often brought out for no better purpose than to advertise an individual physician or a group of physicians, and in place thereof devote this time to a serious study and the space thus saved to an adequate representation of problems in medical economics, we would, I believe, have smoother sailing and accomplish more good as a profession.—*E. H. Ochsner, M.D., Am. Med.*, XIX, 40, 1924.

PRE-OPERATIVE AND POST-OPERATIVE CARE OF SURGICAL PATIENTS*

A. E. SOHMER, M.D., F.A.C.S.

Mankato Clinic

Mankato, Minnesota

The care of surgical patients is interesting from several standpoints, but we wish to bring before you a few of the more interesting points of practical importance in the care of surgical patients before and after operation, not touching upon the actual operation or anesthesia of the patient.

Time of Entry Into Hospital.—Whenever possible, the patient should be in the hospital the night before operation, and in the more serious cases forty-eight hours is not too long. At this time the records can be completed, the physical examination and laboratory tests made, the diet regulated, fluids and alkalies administered, if indicated, the field of operation prepared, and the patient will become acclimated to his surroundings.

Mental State.—It is well known that fear has a great influence on the physical condition of the patient, especially in relation to shock, and the psychic influence of the surgeon and hospital attendants is an important factor in preparing a patient for operation. When the patient has confidence in his surgeon, and the hospital attendants show that they know what they are about, without undue bluster, it imbues the patient with assurance, and goes a long way towards a comfortable convalescence. Visitors should be mostly excluded, because, as a rule, they think of the improper things to say to a patient. The patient should be kept quiet, so that he can sleep well and reach the operating table without fear.

Hospital Records.—It is important that an accurate history, written in descriptive phraseology, be recorded, and that a proper interpretation be made of this history. A thorough physical examination should be made and recorded, paying special attention to the heart, lungs, kidney function and blood pressure. Necessary laboratory tests should be made and recorded: while laboratory findings are not conclusive, yet when properly correlated to the physical findings, they are a valuable aid in modern diagnosis.

Special Preparation.—Throat and mouth should

*Read before the Southern Minnesota Medical Association, Mankato, May, 1924.

be examined, and the presence of an acute respiratory infection should be noted and treated, postponing operation until a satisfactory condition can be attained. A dirty mouth or an acute infection in the nose and throat often leads to serious post-operative conditions, especially when an anesthetic is given. Digitalis is a great help in supporting the heart and circulation, especially when a serious operation is undertaken, and where there is evidence of myocardial weakness and circulatory incompetence. Digitalis for two or three days before operation is often a great help in turning the tide towards a good recovery. It is much better than stimulation with strychnia or whiskey. Quick acting stimulants should be used only as a whip in an emergency, and never in the preparation of a patient.

Fluids.—It is usually wise to give plenty of fluids by mouth, and, if necessary, by rectal drip or intravenously. The addition of alkalis improves the general state of the body, especially when exhausting disease or starvation tends to a condition of acidosis. One can give fluids to within a short time of the operation with benefit.

Cathartics.—A much abused method of preparation consists in giving excessive cathartics. These produce congestion, sometimes acute enteritis, and often dehydration, and may cause post-operative vomiting, tympanites and so-called gas pains. Where a patient's bowels have been normal, no physic should be given. Under no circumstances should a cathartic be given within forty-eight hours of the operation. Much better technique consists in a careful and thorough colon flushing with normal salt solution, than any other method of bowel preparation.

Preparation of the Local Field of Operation.—A good routine, when there are no contraindications, is to give the patient a general bath or a sponge bath the day before, to carefully shave the field of operation without causing irritation, put on a clean binder and do nothing else until immediately before operation, when, depending upon the choice of the operator, benzene, followed by iodine and alcohol, or 5 per cent picric acid solution, or phenoco solution should be used, the object being to cleanse the superficial skin and not attempt a thorough skin sterilization. It is impossible to reach the bottom of the fat, sweat and hair follicles, and during an operation, these will empty on the skin, no matter what previous preparation

has been undertaken. If the skin is irritated, there is a greater danger of infection than otherwise. After cleansing, and the use of one of the above mild applications, protection of the skin with sterile towels is sufficient and efficient. We desire cleanliness, not irritation. In females, a cleansing but not an antiseptic douche is best, and if vaginal work is to be done, then a cleansing with a mild lysol solution meets the indication. Iodine is sometimes used, but there is a great danger of subsequent irritation, and this should be avoided. To sum up the preparation of the field of operation, we must emphasize that if we are reasonably clean, use mild applications, and avoid irritation by proper skin protection with drapes, then we meet the indication, and do not predispose to subsequent infection.

Morphine with scopolamine or atropine is indicated in most cases, as it quiets the patient, facilitates the giving of a general anesthetic, and keeps the patient quiet after operation. Judgment must be used in this, depending upon the case, and the general make-up of the patient. It is sometimes wise to give the patient 8 or 10 grains of veronal the night before, to assure a good night's rest before operation.

Every surgical clinic should have at hand grouped blood donors, materials and equipment for giving intravenous saline or hypodermoclysis, and a supply of fresh adrenalin to be used when loss of blood or shock occurs.

Special Operations.—In certain fields or types of operation, special preparations are indicated, and it is in these cases that such wonderful progress has been made in modern surgery, and mortality as well as morbidity has been greatly reduced. First, it is wise for each tonsillectomy case to have a urinalysis, lung examination and blood coagulation test made beforehand, to ward off any alarming emergencies. Second, goiter; the proper selection of cases for operation, depending upon the type of goiter, the history of the case, the rate of metabolism and amount of degenerative changes locally as well as in the important organs of the body, has increased the operability and improved the operative mortality materially. Preliminary rest, the use of Lugol's solution, operation in several stages, from simple ligation to complete thyroidectomy, with or without immediate closure of the wound, must all in turn be used, depending upon the indication; and keen judgment and pa-

tience bring their own reward. Biliary infections require, above all, a knowledge of the coagulability of the blood, and, where this is slow, the preliminary intravenous injection of calcium chlorid solution, giving 5 c.c. of a 10 per cent solution daily for two or three days, as indicated, a treatment which Doctor Wolters has brought before the profession and emphasized with illustrious results; it has been a great saver in gallbladder operations. Diabetic cases in need of surgical care require a careful preliminary preparation, with the establishment of a proper sugar tolerance, with or without insulin. Where formerly a diabetic gangrene in the toe required an amputation above the knee, we now, with the patient in the proper condition, can often ablate the dead tissues without interfering with the local circulation, and find almost normal granulation and healing as our reward. Prostatectomy cases should have the proper kidney secretory balance established before operative procedure is undertaken. The bladder should be decompressed gradually, watching the blood pressure until it is stable, checking the excretory function, and noting the blood retention of creatinin and blood urea or non-protein-nitrogen; and with the two-stage operation we can promise definite results, where formerly it was a hazardous and doubtful undertaking. As mentioned before, in cases with myocardial or circulatory unbalance, the giving of digitalis for two or three days beforehand is of great help.

Record of Operation.—It is always wise to note carefully the pre-operative diagnosis as well as the post-operative diagnosis on the chart at the hospital, to note the findings, as well as all the operative steps undertaken; the type of incision and the kind and location of drains and sutures should be noted.

Post-operative Care.—Transportation of the patient from the operating room to the bed should be made so as not to disturb sutures and drains. A competent doctor or nurse should accompany the patient, and stay with the patient until he is out of all danger. The patient should be protected against exposure; the bed, properly prepared beforehand and warm, should be in such a position of head elevation or foot elevation as is indicated by the operation. Position of the bed and posture of the patient mean a lot in the prevention of adhesions, phlebitis, embolus, and in the treatment of shock. A rectal drip should be used, when indi-

cated; but unless there is shock or a poor circulation, it is wise not to use it, since it tends to cause gas pains and nausea. We find a good method to be one in which the can containing the fluid is placed on a table, level with the rectum, and a short tube, just long enough to pass the sphincter, is inserted and left in situ. The rectum will absorb fluid according to the amount it can absorb, and the patient will expel gas through the can. For this an alum solution or normal salt solution serves well. The nurse, of course, should note the condition of the pulse, temperature and respiration, the facies and mentality of the patient, the amount of excretion, such as bile, urine, etc. If there is cardiac weakness, digitalis might be indicated. If there is dilatation of the stomach, gastric lavage and placing the patient in a prone position relieves the mesenteric pull on the duodenum, which is usually responsible. The giving of fluids may be started almost as soon as the patient desires them, hot water being best. It is easier to vomit with water in your stomach than with an empty stomach. The giving of food should be started as soon as conditions permit. Paralytic ileus without mechanical obstruction is best treated by gastric lavage, prone position of the patient, the introduction of a colon tube and, if necessary, a high and early enterostomy. Mechanical ileus requires a high enterostomy and secondary operation, before it is too late. The bladder should be watched, and if the patient cannot void spontaneously, and all routine attempts have been made, and the patient is in discomfort, there is no harm if catheterization is done *properly*, and a solution of argyrol, lunosol or other suitable antiseptic is immediately put into the bladder before withdrawing the catheter. After each operation the kidney function should be watched, which can be best stimulated by the introduction of fluids into the body.

Bowels.—The after care of the bowels is important. Do not give cathartics if you can help it. The use of a rectal tube, the above mentioned method of using a can on the level with the rectum, or a bowel irrigation meets the indication better.

Pulmonary Embolus is a tragic occurrence which we can never predict. In serious operations on the pelvic organs or rectum, it is important that the patient be kept quiet for twelve days, and that no large enema or cathartic be used. Elevating the foot of the bed to improve the return circulation from the lower extremities is important, espe-

cially when there has been infection in or near any of the important pelvic vessels.

Secondary collections of infectious fluids should be looked for and drained when they occur.

Dressings should be made with the "hands off" technique, with forceps. The wound should be inspected twenty-four or forty-eight hours after operation; the dressings should be changed at the proper time. In removing sutures, it is better to cut them one day and remove them in twenty-four or forty-eight hours. Because wounds are infected, one should not be careless in changing dressings, since you can get another type of infection which is worse than the first. This is especially important in traumatic injuries of the extremities, and

we find that even in the presence of infection, if we treat the whole limb just as carefully as if we were preparing an abdomen for operation, and keep the whole limb protected with sterile drapes during the healing process, we get kindlier healing and better function.

We think it is a wise plan to give the patient a record of the operation—in other words, an inventory of his remaining as well as his missing organs, for obvious reasons; both for his own information, as well as for the use of any further medical attendants.

A follow-up record of each surgical case works for the benefit of the patient, as well as of science, and in such institutions where social service can be had, it is worth while.

GOOSE GREASE FOR HAPPINESS

Any young interne in a loud-smelling hospital will tell you that the all-wise "Doc" of our boyhood days was an animated reservoir of ignorance. Likewise, the trained nurse with the hazel eyes will assure you that the old ladies who used to group themselves around every sick bed were merely advance agents for the village undertaker.

Bread-and-milk hot-packs are not what they used to be. The bag of "assifidity" hung around the neck is not recognized by Johns Hopkins as a preventive of measles. Serum takes the place of goose grease.

Physicians revise all of their beliefs every forty years. If the long-whiskered practitioner of the eighties, who could cure anything with calomel and morphine, is derided by the specialists of today, may we not predict that the present crop of specialists will be laughed at by the super-specialists of 1950?

They tell us that all of the pallid heroines of history were not broken-hearted, as reported. You can't break a heart. It is a combination of outer casing and rawhide. All of the anemic maidens we have read about were suffering from a lack of vitamins. The balanced ration may take most of the romance out of the world. It is almost impossible to be in love and feel well at the same time.

A venerable lady who smoked a pipe told me, many years ago, that white walnut bark should be peeled from the tree in the dark of the moon. If peeled upward, it was a purge. If peeled downward, it was an emetic. She spoke with much conviction.

The pin-feathered medical student will say that the old lady was daft. How does he know? Has he ever tried out white walnut bark in a large number of cases, working in

the dark of the moon, peeling first upward and then *vice versa*? He won't even admit that sassafras tea, taken in the spring, thins the blood which has become all thickened up with sausage and buckwheat cakes during a long winter. This, in spite of the fact that millions of people have actually diluted themselves with sassafras, and are ready to make affidavits.

We come now to the buckeye or petrified potato, carried in the trousers pocket as an antidote for rheumatism. No sense to it? Well, it's just as easy to explain the buckeye as it is to explain the radio.

If a large number of trustworthy citizens and God-fearing women testify that a woolen sock around the neck will drive away sore throat, that turpentine and sugar will cure a cold, that mutton tallow, gunpowder and a certain bittersweet bark cooked up together will dispel the itch, that catnip will relieve indigestion and skunk oil invariably banishes bronchial inflammation, while a flaxseed poultice will often do just as much good as a trip to the Mayos, how can we go against such a mass of evidence?

Out in the brush there is still an occasional old-fashioned mother who keeps the baby lubricated and calmed down by permitting it to work on a strip of bacon rind. This is contrary to all rules. The babyologists say that a young and toothless child requires orange juice. Yet thousands of bacon-rind babies have grown up to be congressmen, chiropractors, county agents, actresses and officers in the Federation of Women's Clubs.

Let Dr. Billings and the Harvard savants say what they will, when the children out our way begin to act squirmy, we will give them pumpkin-seed tea.—George Ade, *The Cosmopolitan*, September, 1924.

The St. Cloud Meeting

This recent meeting, and notably certain expressions in the House of Delegates, indicates the firm conviction of a large number of members, that larger portions of future programs must be clinical in character. This is a logical stand and while an outgrowth in part of the splendid accomplishments of the now famous Tri-State gathering, is not entirely the result thereof. We have had the various Clinic Weeks with an ever larger number of small special society group meetings, in which stereotyped papers have long been "taboo." Nevertheless, these clinical meetings will not go unless they are held rigidly to some form, structure, and sequence; unless each clinician has some message which he can effectually mobilize and present. "Clinic Weeks" cannot for example gravitate into marathons from hospital to hotel or meeting place, with only a scattering attendance at many of the sessions. Any sort of a preacher needs someone in the pews; only a fanatic can be eloquent in a hollow cave.

This is no academic and immaterial problem when we survey what actually happens to our medical programs and the St. Cloud meeting is fresh enough in our minds to make certain reviews useful. Both sections had very fine programs and the joint sessions were noteworthy and timely. Yet the sessions of Thursday began with only a "baker's dozen" on the benches; the men who came arrived late and were not ready to attend the session until most of the papers had been given. The suggestion was passed out by some that the place of meeting was not sufficiently central; that the Twin Cities should be the logical and constant meeting place. The St. Cloud committee had made arrangements for the physical comfort and mental relaxation of those who attended that have never been surpassed by any city in Minnesota acting as our host. A paved road made it only two hours further than the Twin Cities for anyone residing near thereto, and it brought the meeting to those in the west and northwest a little closer than ever before. Much argument may be advanced in favor of a constant central meeting place, but it must never be forgotten that large attendance records in large centers can easily represent the registration of a definite percentage of local men who only grace the banquet or smoker by their presence, or direct the golf tournament.

Finally, the joint session of Thursday afternoon brought to Minnesota (distinctly through the efforts of Dr. Charles Hensel) the most noteworthy presentation of the whole meeting: Dr. Carl R. Moore, of the University of Chicago, came, with a most interesting review of his work on the testes and the function of the scrotum. The Steinach episode in medical research has brought a deal of unpleasant notoriety to our profession that can only reflect the subumbilical seat of the intelligence in a considerable segment of the body politic. In so far as our profession has lent itself to the exploitation of the ideas concerned, we indicate fully our own incorporation into that segment. Dr. Moore's orderly, instructive, dispassionate and convincing researches indicate clearly the facts involved and the general futility of Steinach's attempt at rejuvenation. Due to the fact that the *early and late* sessions of every program received scant courtesy and attendance, he had, with the other excellent men of the Friday afternoon program, a very small audience.

New Year's is our usual time for sublimity and

resolutions. Let us anticipate that event somewhat while certain matters are fresh in our minds: Let us here and now resolve that whenever and wherever we attend medical meetings, we will make early hotel and banquet reservations, and we will come early and stay late.

E. L. T.

Scarlet Fever

At a time when doubt has been expressed as to the specificity of the streptococcus in disease, it is extremely interesting to find that so familiar a disease as scarlet fever may be definitely attributed to a specific streptococcus. Dochez, Tunnicliff, and others had shown that the streptococcus, which could be isolated in practically 100 per cent of the cases of scarlet fever during the week of onset, gave specific immunologic reactions. It remained for Dick and Dick to show that the disease can be experimentally produced by the application of a particular streptococcus to the throat of susceptible adults. In their investigations they were able to rule out the possibility of an ultra-microscopic virus and to show that it was definitely the streptococcus that was the etiologic factor. Their results are further of interest in showing that the cultural characteristics of the organism were not identical in the 100 cases studied, 84 per cent of the organisms fermenting manite and 16 per cent not doing so. The fact that they were able to produce scarlet fever with an organism of each type indicates that the cultural characteristics need not be the same, although the identical clinical picture is produced.

Dick and Dick have fulfilled all four of the canons of Koch in their demonstration of the streptococcus as the etiologic factor in scarlet fever. In their later work they were greatly helped by their skin test for susceptibility to scarlet fever. This is comparable to the Schick test in diphtheria. The filtrate of the streptococcus is injected intracutaneously and the result read after twenty-four hours. By means of this test susceptibility to scarlet fever can be determined. By repeated injection of the same antigen, they were able to immunize patients against scarlet fever.

Dick and Dick, as well as Dochez and his co-workers, have produced a scarlet fever antitoxin. The results to date seem to show that this antitoxin is useful in the acute toxemia of scarlet fever similar to the toxemia of diphtheria. If it is to be

used, it must be given in the first days of the illness. Progress has been made both in the treatment of the acute stage of scarlet fever and in the prevention of the disease itself.

H. F. H.

Dr. Archibald MacLaren

The passing away of Dr. MacLaren leaves a gap in our ranks which it will be difficult to fill. His absence at our state meeting in St. Cloud due to his illness was sorely felt but his departure so soon after the convention came as a shock to most of his friends and acquaintances.

The presidency of our state organization is an indication of the esteem felt for Dr. MacLaren by his fellow members. The position he held in the medical profession of the state was truly enviable. He was one of the outstanding figures in surgery of the Northwest, a position he not only held because of his long professional experience, industry and natural ability but because of his unusually fine character. Perhaps the outstanding quality was his absolute honesty in all his dealings. His friends at times feared his openness would work to his detriment. It never did.

While we have lost a friend, those who knew him will always retain the inspiration of his life.

Dr. Frederick Lee Beckley

As a sad coincidence, we are called upon to report the death also of our treasurer, Dr. Frederick Lee Beckley, Treasurer of the Minnesota State Medical Association for six years, he was again re-elected at the last annual meeting. Those of us who were at the St. Cloud meeting saw our friend, Dr. Beckley, who seemed in the best of health and just as keen for a round of his favorite game of golf as he ever was.

Dr. Beckley attained the enviable position he held in his community and among his professional associates through his real worth. As president of the Minnesota Transfer state bank, he was active in the business life of the Merriam Park district of St. Paul, as well as serving it professionally.

Those of us who knew Dr. Beckley will always remember that he played the game of life fairly and played it well. What more can be said of a man?

OBITUARY

DR. ARCHIBALD MacLAREN

Dr. Archibald MacLaren, leader of long standing in the medical profession in St. Paul and the Northwest, died early Sunday, October 12, at his home, 353 Summit avenue.

Death was due to an affliction of the heart, with which he had been suffering for two years, but which did not become acute until recently. Until serious illness overtook him he carried on the practice of surgery and the duration of his service to the profession placed him among St. Paul's oldest surgeons.

Long service and widely recognized abilities imposed many distinctions on him. He was chief of the staff of St. Luke's hospital, member of the staff of the Miller hospital, fellow of the American College of Surgeons, member of the American Surgical Association and the American Medical Association, state and county medical associations and he had been associate attending surgeon at the University hospital and professor of surgery at the University of Minnesota. He was president of the Minnesota State Medical Association at the time of his death.

Dr. MacLaren was born in Red Wing in 1858 and, with the exception of the years given over to education, he remained virtually all of his life in this state. When he was 10 years old he came to St. Paul with his father, General Robert N. MacLaren, celebrated Indian fighter, who was one of St. Paul's influential citizens in the days when the frontier was near at hand.

Dr. MacLaren received his early education in St. Paul grade and high schools and his academic preparation for medical study at Princeton university, from which he was graduated in 1880. He received his professional education at the College of Physicians and Surgeons of Columbia university. Then for two years he was an interne in the New York Women's hospital, after which he returned to St. Paul.

His first professional association was with Dr. Edward C. Spencer in 1885. Later he was associated with Dr. C. A. Wheaton, with whom he practiced until 1896. Two years later he joined with Dr. Harry P. Ritchie, and that association grew until at the time of Dr. MacLaren's death, it included Drs. MacLaren, Ritchie, Louis E. Daugherty and Harry Oerting.

Surviving him are the widow, who before her marriage in 1839 was Miss Katherine Dean; three children, Margaret, Katherine and Archibald MacLaren, and a sister, Mrs. George E. Ingersoll.

DR. HORACE H. WITHERSTINE

Dr. Horace H. Witherstine, 72 years old, prominent Rochester physician and former state senator, was killed Thursday, October 2, when the car in which he was driving skidded and turned over on a highway two miles north of town. Dr. Witherstine was alone in the car when the accident occurred and was on his way to make a rural call.

Dr. Witherstine for many years practiced medicine in Olmsted county and always took a prominent part in poli-

tics in that district. He was elected to the state senate in 1902 and was re-elected four years later. He also served two terms as mayor of Rochester in addition to serving as alderman and member of the school board at various times. In 1916 he was democratic nominee for congress from his district.

Dr. Witherstine was born at Herkimer, N. Y., April 14, 1852. His early life was spent on a farm and later he taught school for 10 years. In 1882 he began the study of medicine and was graduated from Rush Medical College, Chicago, in 1886, later locating in Rochester.

Dr. Witherstine for several years was editor of the Rochester Bulletin, which is now owned and operated by his son, Glenn. Besides this son he is survived by his widow, one other son, Dr. William H. Witherstine, Grand Forks, N. D., and Mrs. Russell Drake, of Rochester, a daughter.

DR. HENRY EDWIN DOUGLASS

Dr. Henry Edwin Douglass was born at Napanee, Ont., on February 14, 1868. His preliminary education was obtained in the Napanee Collegiate Institute and his medical education in the Medical Department of Queen's University, at Kingston, Ont., from which he graduated in 1892. He began his professional life at Morrisville, Vt., locating there five years before going to Iowa. For fourteen years he practiced at Independence, Ia., and the following four years at Hutchinson, Minn. His Minnesota certificate was issued in 1914. He served twenty-three months in the U. S. Army Medical Corps. For the past five years he resided at Blackduck, Minn., and was active in practice up to two or three days before his death, which occurred on June 14th of this year from acute dilatation of the heart. For the past four years he has been a member of the Upper Mississippi Medical Society and the Minnesota State Medical Association. He is survived by his wife, Mrs. Mabel Douglass, and daughter, Agnes. The funeral was held from his home at Blackduck, under the auspices of the Masonic Lodge, and remains interred in the Lakeview Cemetery.

IN MEMORY OF DR. ROBERT HYNDMAN MULLIN

The Administrative Board of the Medical School learns with regret the death of Dr. Robert Hyndman Mullin, formerly a member of this faculty, an associate professor of pathology and bacteriology, and an officer of the Minnesota State Board of Health.

He did valuable service for the Medical School during the years of his association with it. He was an earnest teacher, a good executive, a competent laboratory director. He gave himself unsparingly to the promotion of medical education and public health.

The faculty extends to his family the sympathy of its many members who remember Dr. Mullin kindly for his many sterling qualities and gratefully for the educational service he rendered to the State of Minnesota.

E. P. LYON,
Dean.

RICHARD OLDING BEARD,
Secretary.

REPORTS AND ANNOUNCEMENTS OF SOCIETIES

THE STATE MEETING

The annual meeting of the Minnesota State Medical Association was held at St. Cloud October 8, 9 and 10, 1924. The registration was 310 of the total membership of 1,952 in the Association. While this registration was the smallest for several years, the attendance at the various scientific meetings was fully as good as usual. This may be accounted for by the fact that most of those in attendance stayed for a longer portion of the program than is usually the case when the meeting is held in the Twin Cities.

In the House of Delegates the matter that received most discussion was the advisability of a full time secretary, a matter which has been brought up from time to time and a step which undoubtedly would react to the benefit of the Association. The expense of such a step makes it prohibitory without a substantial increase in the state membership dues. There was considerable opposition to any increase in dues and so the matter of securing an executive secretary, who will be able to devote more time to field work, was left to a committee appointed by the Council.

The desirability of employing a full time secretary is doubted by no one acquainted with Association activities. Few perhaps realize the amount of detail work which the affairs of an association of physicians numbering close to 2,000 entails. The present executive secretary has developed a fine system of bookkeeping and files for handling the secretarial work and the Association has been fortunate in having such competent service.

The program this year was excellent. Few physicians plan to be present at the opening and closing addresses of a convention and this year was no exception. The last session was a combined meeting and the attendance dwindled pitifully. Most of the members had to leave early in order to get home for dinner at a seasonable hour. It will be interesting to see how the recommendation of the House of Delegates, that there be more combined meetings and more clinical presentations next year, will work out.

The approval of the lay journal known as the Northwest Health Journal and published by the Minnesota Public Health Association was voted by the House of Delegates. It was also voted to continue the appropriation for assisting in the Public Health Exhibit at the State Fair next year.

The following officers were elected for the year 1925:

President—W. L. Burnap, M.D., Fergus Falls.

First Vice President—A. S. Hamilton, M.D., Minneapolis.

Second Vice President—John Libert, M.D., St. Cloud.

Third Vice President—C. W. More, M.D., Eveleth.

Secretary—Carl B. Drake, M.D., St. Paul.

Treasurer—F. L. Beckley, M.D., St. Paul.

COUNCILORS

First District—G. S. Wattam, M.D., Warren.

Fourth District—W. H. Condit, M.D., Minneapolis.

Seventh District—F. A. Dodge, M.D., Le Sueur.

DELEGATES TO THE AMERICAN MEDICAL ASSOCIATION

Delegate—J. L. Rothrock, M.D., St. Paul (2 years).

Alternate—J. G. Cross, M.D., Minneapolis (2 years).

Delegate—T. L. Chapman, M.D., Duluth (2 years).

Alternate—Theo. Bratrud, M.D., Warren (2 years).

The invitation extended by Minneapolis to hold the convention there next year was accepted. The time tentatively determined upon by the Council was the second week in October.

LYMANHURST AND PARKVIEW STAFF MEETING

The regular monthly meeting of the Lymanhurst and Parkview medical staffs will be held at Lymanhurst School, 1800 Chicago Avenue, Minneapolis, Tuesday evening, November 25, at 7:00 o'clock.

Following is the program for the evening:

"Tuberculosis and Diabetes," Dr. L. F. Richdorf.

"Diet and General Therapy in Tuberculosis in Children," Dr. Fred W. Schlutz.

"Pleural Effusions and Operative Procedures in Tuberculosis and Other Closely Allied Conditions in Children," Dr. E. J. Hucnens.

"Intestinal Tuberculosis and Closely Allied Conditions in Children," Dr. Rood Taylor.

All persons interested in tuberculosis are invited to attend these meetings and participate in the discussions.

MINNESOTA MEDICAL ALUMNI ASSOCIATION

A meeting of the Minnesota Medical Alumni Association was held in St. Cloud on October 10, 1924. President Dr. Paul B. Cook was in the chair.

The following officers for the ensuing year were elected:

Dr. O. N. Meland, Warren, Minn., President.

Dr. J. Warren Bell, Minneapolis, Vice-President.

Secretary and Treasurer, as formerly, Dr. Donald Daniels, Minneapolis.

Dr. E. P. Lyon, dean of the medical school of the University, addressed the meeting and discussed some of the problems confronting the medical school and medical education in general.

The President, Dr. O. N. Meland, appointed the following men to fill vacancies occurring upon the Advisory Committee to serve for a period of three years:

Dr. S. P. Rees, Minneapolis; Dr. E. L. Tuohy, Duluth; Dr. Paul B. Cook, St. Paul; Dr. Carl O. Estrem, Fergus Falls. Also as Medical Representative at Large, Dr. S. E. Sweitzer, Minneapolis. J. WARREN BELL, Acting Secretary.

AMERICAN WATER WORKS ASSOCIATION MINNESOTA SECTION

The fourteenth annual meeting of the Minnesota Section of the American Water Works Association will be held in the main engineering building, room 305, at the University of Minnesota, November 14, 1924. The session begins at 9:30 A. M. and the program includes subjects pertaining to public health questions which will be of interest to the medical profession.

The subjects which will be discussed include: "Problems Dealing With the Elimination of Lubricating Oil in the Water Supply Which Has Been Introduced Through the Pumping Equipment," "Stream and Lake Pollution," and "Simple Goiter: Its Prevalence and Prevention."

OF GENERAL INTEREST

Dr. Harry T. Frost, formerly of Hallock, has moved to Crookston for the practice of his profession.

Dr. W. F. Bleifuss, Rochester, has discontinued his work as city health officer at Rochester, and plans to retire from medical practice entirely the first of this month.

Dr. Fred W. Behmler, formerly of Lafayette, has taken over the practice of Dr. M. J. Fiksdal at Appleton, Minnesota, where he has been located since September.

Dr. Carl M. Oberg, Minneapolis, with his wife and daughter, Margaret, has returned from a five months' trip in Europe. Dr. Oberg spent two months in the eye and ear clinics of Vienna.

Dr. Robert Emmett Farr read a paper before the Linn County Medical Society, September 11, at Cedar Rapids, Iowa, and another before the Pennsylvania State Medical Association meeting at Reading, Pa., October 8th.

Dr. Arthur Margot, formerly Pathologist and Director in Charge of the Milwaukee County Laboratories, Milwaukee, Wis., has recently accepted the position of Pathologist and Director of the Clinical Laboratory with the Sioux Falls Clinic, Sioux Falls, S. D.

Dr. George E. Fahr, Minneapolis, read a paper on "The differential diagnosis of rheumatic fever and subacute bacterial endocarditis" before the meeting of the Minnesota Pathological Society, held at the Institute of Anatomy building, University of Minnesota, Tuesday evening, October 21.

The new Hudson-Towers hospital-hotel in New York City, representing an investment of \$3,500,000, is nearing completion. This new hospital-hotel combination is to be an open hospital and will meet a definite need. The unique combination of hospital for the sick and hotel for the relatives is particularly needed in New York, where such a large percentage of the population lives in hotels.

The 1924 roll call of the American Red Cross, to enroll members for 1925, will be held from Armistice Day to Thanksgiving Day, November 11 to 27. The membership this year is well over three and a quarter millions, with an additional junior membership of five and a half millions. The service of the American Red Cross is increasing and daily proving its value and it is felt that increase in membership is essential to its proper development.

Announcement has been received of the Warren Triennial Prize to be awarded for the best dissertation considered worthy of a premium on some subject in Physiology, Surgery, or Pathological Anatomy; the arbitrators being the General Executive Committee of the Massachusetts General Hospital, Boston. The prize was founded by the late Dr. J. Mason Warren in memory of his father.

The rules of the competition are as follows:

Dissertation must be either in the English, French, or German language, and must be typewritten and suitably bound, so as to be easily handled. Work that has been published previously will not be considered in competition. The name of the writer must be enclosed in a sealed envelope, on which must be written a motto corresponding with one of the accompanying dissertation. The amount of the prize for the year 1925 will be \$500.00. Dissertations will be received until April 15, 1925, and should be sent to

Dr. Frederic A. Washburn, director of the Massachusetts General Hospital.

University News.—More than \$3,000,000 for the support and extension of instruction in medicine, nursing, and allied fields, has been received as gifts by the University of Minnesota in the past 12 years, President L. D. Coffman told those who attended the cornerstone laying for two hospital units on the University of Minnesota campus, Wednesday, October 1.

He enumerated these gifts as follows:

\$120,000 from the heirs of Dr. Adolphus F. Elliot for the Elliot Memorial hospital.

\$42,000 from various Minneapolis citizens for the hospital site.

\$1,500,000 from the Mayo Clinic to be used as the Mayo Foundation, which sum has been increased by accumulated earnings to \$2,090,000.

\$1,000,000 from William Henry Eustis for a hospital and home for crippled children. (Final payment to be made by July 1, 1927.)

\$20,000 from Mrs. Frank C. Todd, \$20,000 from Mrs. E. C. Gale, and \$5,000 from Mrs. Emery Mapes for the Todd Memorial Eye, Ear, Nose, and Throat hospital.

\$250,000 from the Citizens Aid Society of Minneapolis for the George Chase Christian Memorial Cancer Institute.

President Coffman sketched the history of medical education at Minnesota during the past 12 years and said that the erection of Elliot hospital marked an era in the life of the Medical School.

"Another era was begun," he said, "when Drs. W. J. and Charles Mayo gave to the university \$1,500,000 with the understanding that the interest from this endowment would be converted back into the principal until the total reached \$2,000,000, and with the further understanding that the income would be devoted thereafter perpetually to research in the fields of medicine and surgery. Two years ago this magnificent gift with its accumulated earnings reached the sum of \$2,090,000, which means that the University has annually from this source alone more than \$100,000 for the study of problems relating to human health.

"Although the Mayo Foundation has been in existence since 1915, from the very beginning the Mayo Clinic has contributed out of its resources between \$200,000 and \$300,000 a year to the Foundation for the scientific study of human diseases. Today we are expending approximately \$350,000 a year, which is the income from the Mayo Foundation and the annual gift of the Mayo Clinic, to maintain graduate work in medicine and surgery at the University of Minnesota. In this respect, Minnesota is unparalleled among the medical schools of the world.

"For twelve years Elliot hospital has stood alone. Now, again, we come together to celebrate the laying of the cornerstones of two new hospital units," he said, "one for diseases of eye, ear, nose, and throat, made possible by the gifts of Mrs. Todd, Mrs. Gale, and Mrs. Mapes, supplemented by funds of the University, and the other to be devoted to the study of cancer, made possible by a gift of \$250,000 by the Citizens Aid Society, which was founded by Mr. George Chase Christian. These two new hospitals mark another step in the development of medical education at the University of Minnesota."—University of Minnesota News Bulletin.

NEW AND NON-OFFICIAL REMEDIES

The following articles have been accepted by the Council on Pharmacy and Chemistry:

ABBOTT LABORATORIES:

Metaphen

Metaphen Solution 1:5,000

SWAN-MYERS COMPANY:

Sterile Ampules of Mercury Benzoate, 2 per cent

Sterile Ampules of Mercury Biniodide (Oil Solution)

Sterile Ampules of Mercury Salicylate, 0.097 Gm.
(1½ Gr.)

Sterile Ampules of Mercury Salicylate, 0.065 Gm.
(1 Gr.)

Sterile Ampules of Mercury Succinimide, 0.01 Gm.
(⅓ Gr.)

NEW AND NON-OFFICIAL REMEDIES

Medicinal Dyes.—The dyes which are used in medicine may be divided into five classes: (1) the azo dyes, of which scarlet red medicinal and scarlet red sulphonate are described in New and Non-official Remedies; (2) the acriflavine dyes, such as acriflavine, neutral acriflavine and proflavine; (3) the fluoresceine dyes, usually combined with metal mercury such as mercurochrome—220 soluble and flumerin; (4) the triphenolmethane or rosaniline series, such as gentian violet, crystal violet, methyl violet and fuchsin; and (5) miscellaneous dyes, such as methylene blue, phenolsulphonaphthalein and tetrabromphenolphthalein. In order to obtain comparable results when employed clinically, dyes should be of constant composition. The triphenolmethane (rosaniline) dyes include fuchsin and the closely related violet dyes, gentian violet, crystal violet and methyl violet. Of these, gentian violet is the one that has been used chiefly in medicine. It is stated to have the property of great penetration; to be bactericidal also bacteriostatic in vivo toward selective organisms. Its chief use has been in the treatment of infections of the pleural cavity and of the joints. The intravenous use of gentian violet has also been proposed in staphylococcus septicemia, chronic cystitis, osteomyelitis.

Gentian Violet Medicinal.—A mixture of pentamethylpararosaniline and hexamethylpararosaniline chlorides. For direct application, a solution of from 1:500 to 1:1,000 may be employed; for instillation, a 1:10,000 solution. For intravenous use, 5 Mg. per Kg. of body weight, injected in 0.5 per cent solution has been used.

Gentian Violet Improved Medicinal.—A brand of gentian violet medicinal-N.N.R. Colcman and Bell Co., Norwood, Ohio.

Gentian Violet Medicinal—"National."—A brand of gentian violet medicinal-N.N.R. National Aniline and Chemical Co., New York.

Insulin-Stearns Quadruple Strength.—Insulin-Stearns (see Journal A.M.A., June 14, 1924, p. 1937) marketed in 5 c.c. vials containing forty units in each c.c. Frederick Stearns & Co., Detroit.

Sulpharsphenamine-Squibb, 1 Gm. Ampules.—Each ampule contains sulpharsphenamine-Squibb (see New and Non-official Remedies, 1924, p. 68) 1 Gm. E. R. Squibb & Sons, New York.

Sulpharsphenamine-Squibb, 3 Gm. Ampules.—Each ampule contains sulpharsphenamine-Squibb (see New and Non-official Remedies, 1924, p. 58) 3 Gm. E. R. Squibb & Sons, New York.

Diphtheria Toxin-Antitoxin Mixture (new formula).—Diphtheria toxin-antitoxin mixture-Squibb (see New and Non-official Remedies, 1924, p. 298) marketed in packages of thirty 1 c.c. ampules. E. R. Squibb & Sons, New York.

Antistreptococcic Serum-Squibb.—Antistreptococcic serum-Squibb (see New and Non-official Remedies, 1924, p. 305), marketed in packages containing one 10 c.c. syringe; in packages containing one 50 c.c. vial. E. R. Squibb & Sons, New York.

Antistreptococcic Serum Rheumatic-Squibb.—Antistreptococcic serum rheumatic-Squibb (see New and Non-official Remedies, 1924, p. 305), marketed in packages of one 20 c.c. vial; in packages of one 50 c.c. vial. E. R. Squibb & Sons, New York. (Journal A. M. A., Sept. 6, 1924, p. 767.)

Ampules Pituitary Solution Wilson, 0.5 c.c.—Each ampule contains pituitary solution-Wilson (see New and Non-official Remedies, 1924, p. 229) 0.5 c.c. Wilson Laboratories, Chicago.

Thiosinamine.—Thiosinamina. Allylthiourea. Thiosinamine is being used against arsphenamine dermatitis. This use is still in the experimental stage. Thiosinamine was originally introduced to promote absorption of scar tissue, lymphatic swellings, etc. Its restricted use indicates that it has little if any value for this purpose. Although it is usually well borne, except for its bitter taste and acid eructation, it may produce toxic systemic effects, and these may set in suddenly after it has been used for a time without toxic effects. (Journal A. M. A., Sept. 13, 1924, p. 843.)

Oridine.—The calcium salt of the iodized fatty acids of cottonseed oil. It contains from 23 to 25 per cent of iodine in organic combination. Oridine acts in the system similarly to the inorganic iodides. The iodized fatty acid radicle of oridine is not decomposed in the stomach but a part of the iodine is split off when it enters the intestine. The undecomposed portion is readily absorbed and, as in the case of other fats, it is largely deposited in the tissues where it is slowly split up. As with other iodized fats, the action of oridine is exerted more slowly than that of the inorganic iodides. Oridine is marketed in powder and as oridine tablets for the prophylaxis of goiter, containing oridine equivalent to iodine 0.01 gm. Eli Lilly & Co., Indianapolis. (Journal A. M. A., Sept. 20, 1924, p. 921.)

Rabies Vaccine (Human), Phenol Killed.—An antirabic vaccine (see New and Non-official Remedies, 1924, p. 306) prepared according to the general method of David Sempel. The product as sold contains brain substance 2 per cent and phenol 0.5 per cent suspended in physiological sodium chloride solution. It is marketed in packages of fourteen vials and a syringe, and in a package containing 21 vials

and a syringe. Jensen-Salsbery Laboratories, Inc., Kansas City, Mo. (Journal A. M. A., Sept. 27, 1924, p. 1001.)

PROPAGANDA FOR REFORM

BioFood.—This is a "patent medicine" combination put out by a concern that seems to go under various names: "Biochemical Food Products Corporation," "Bio-Products Company," and "BioFood Corporation." BioFood has been shrewdly and cleverly marketed. The impression is given that the stuff is a food and not a medicine. Its high price—ten dollars a treatment—impresses the public with its value. The treatment consists of a box labeled "A" and two bottles labeled, respectively, "B" and "C." BioFood is sold with the claim that our bodies are composed of twelve tissues containing sixteen elements, that our foods are deficient in these elements and that BioFood supplies this deficiency and thus "builds up the body by supplying all the elements which nature intended man to have and thus gives nature a chance to create her own antitoxins and effect a cure." BioFood has been advertised extensively in newspapers, in self-styled medical journals and by cruelly mendacious advertisements in the Chicago street cars. The A. M. A. Chemical Laboratory reports that BioFood "A" may be considered to be composed essentially of milk sugar and flavoring in which have been incorporated small amounts of iron, calcium and manganese salts and phosphate, either as such or in combination such as glycerophosphate. The Laboratory found BioFood "B" to be tablets which may be considered to consist essentially of potassium acetate, sodium chloride, sodium sulphate and sodium citrate. BioFood "C" was a liquid resembling solution of iron and ammonium acetate, U. S. P., modified by the addition of very small amounts of calcium, magnesium and sodium and phosphate compounds. (Journal A. M. A., Sept. 6, 1924, p. 782.)

Mercurochrome-220 Soluble and Gentian Violet Intravenously.—Reports on the intravenous use of mercurochrome-220 soluble and of gentian violet have been published. These drugs, when administered intravenously, are used in recently prepared aqueous solution. Of mercurochrome, 5 mg. per kg. of body weight appears to be generally used. It is used in a one per cent solution. Of gentian violet, 0.25 per cent of an aqueous solution is used; the dosage being 5 mg. per kg. of body weight. Mercurochrome-220 soluble marketed by Hynson, Westcott & Dunning, Baltimore, gentian violet medicinal—"National" of the National Aniline and Chemical Co., New York, and gentian violet improved medicinal of Coleman & Bell Company, Norwood, Ohio, have been accepted for New and Non-official Remedies. (Journal A. M. A., Sept. 20, 1924, p. 942.)

Hectine.—Hectine is said to be sodium benzosulphoamino-phenyl-arsenate and, therefore, is similar in composition to the product "Atoxyl." Atoxyl is one of a class of arsenical preparations, the use of which has been generally discontinued in favor of the products of the arsphenamin type. Hectine has not been accepted for New and Non-official Remedies, nor has the American agent, George J. Wallau, Inc., requested such recognition by the Council on Pharmacy and Chemistry. (Journal A. M. A., Sept. 20, 1924, p. 942.)

RESULTS OBTAINED IN THE TREATMENT OF NON-PULMONARY TUBERCULOSIS: H. O. West (Tubercle, London, 1924). "Does the pulmonary specialist have a greater percentage of cures, i.e., quiescent cases, or, in short, have a greater average of good results than the specialist in non-pulmonary tuberculous cases?" The specialist in the non-pulmonary field claims that he is at a disadvantage when his results are compared with the results in the pulmonary field.

The non-pulmonary specialist has not only to contend with a general infection, a local morbid process and therefore to consider the arrest and the quiescence of the disease both general and local, but, in addition to these, he has to consider the functional orthopedic results. He can claim a case as "disease quiescent" and at the same time the functional result may be a failure. The case may be as follows:

A woman with pulmonary disease may recover with the loss of one lung and still live a long and useful life in her family. But should a man have an arm amputated he is immediately handicapped. No invention to date can overcome the handicap. Similarly, ankylosis of hip joints with faulty positions from tuberculous disease can not be said to be a very credible result. Yet in the few cases named they will be classified as "disease quiescent," and after two years as "disease arrested."

Comparing the "end" results of pulmonary cases and non-pulmonary, we find that in the pulmonary cases the "end" results are becoming more available for statistical reports. In the non-pulmonary the tubercular process may be arrested, but the orthopedic results are less flattering.

When we come to consider the statistics of the results of actual institutional treatment two important points at once appear:

The first is that the proximate, though not the remote, results are vitiated by the inclusion of cases which are

admitted with the disease already soundly arrested. This undoubtedly occurs.

The second point is that while comparisons are always odious, they are impossible unless like is compared with like, and it is therefore futile to compare the proximate results (and in any case I do not propose to offer any comparisons) of an institution which picks its cases and one which admits all and sundry. In one American institution the policy has changed from mixed cases to picked cases, so that the basis of results has altered. A uniform system must similarly be adopted as to "relapse" cases.

For example, a classification has been adopted by the metropolitan Asylums Board whose main groups are:

- Active disease, with slight deformity
- Active disease, with considerable deformity
- Active disease, with abscess
- Disease with sinus formation
- Disease of long standing

To pass finally to the more important remote results. The difficulty of obtaining reliable after-history information year after year is notorious. Some records of pulmonary cases exist and are classical, but the serious thing is that the surgical officer may go on in blissful ignorance of the fact that although he is quite happily rejoicing in his 75, 80 or 90 per cent of "disease quiescent" proximate results, a proportion which may be far from flattering is falling by the wayside with relapses or with steadily degenerating orthopedic results and drifting off into other institutions. This, of course, happens to all of us. It happens especially in all branches of surgery. The surgeon comparatively rarely sees his failures. They go elsewhere.

To summarize—the following general statements about the results of the treatment of non-pulmonary tuberculosis will eventually be supported statistically:

1. That the proximate result of prolonged institutional treatment is to bring about quiescence of the disease in at least 75 per cent of all cases of non-pulmonary tuberculosis.
2. That this result will be maintained in the after history of not less than the same percentage of all cases.
3. That the length of treatment required varies almost directly with the promptitude with which treatment is given after early diagnosis.
4. That the expectation of life will not seriously be diminished in early cases suitably treated, and that diminution will be due essentially to any resulting crippling.

D. FLEMING.

THE CASE AGAINST GASTRO-ENTEROSTOMY:
Donald C. Balfour (Jour. Amer. Med. Assoc., Aug., 1924). The results of gastro-enterostomy for duodenal ulcer were studied so that the procedure might be compared with the more radical operations which are now being advocated by European and American surgeons.

Sherren, the London surgeon, reported satisfactory results in 92.6 per cent of 500 cases, two or more years after operation. He also stated that "patients who go for two years without symptoms never develop them later."

One thousand patients who were operated on ten years or more ago, were the basis of the study reported in this article. Nine hundred and eighty-six patients had complained of pain before operation; only ninety reported a return of pain in any degree and only twenty-two of these considered it sufficient to return for re-examination.

Vomiting was a symptom in 611 of these cases before operation, and only twenty-five reported any recurrence of this symptom. Hematemesis, melena, or both occurred in 286 cases before operation, and recurred post-operatively in only 57 cases (5.7 per cent). Recurring ulcer, whether in the duodenum, stomach, or stoma, was reported in 3.5 per cent of the cases. Subsequent perforation did not occur in any case. Eighty-eight per cent of the patients were entirely relieved of the symptoms for which they sought aid.

An investigation by the Actuarial Society of America disclosed the fact that the life expectancy of people who had had gastro-enterostomies for duodenal ulcer was greater than that of the general population.

The operative mortality was less than two per cent. The failures of gastro-enterostomy are due to: (1) the performance of that operation without definite indication, (2) failure to remove attendant infections in the abdomen, infected teeth and tonsils, (3) coexistence of functional derangement of the stomach, and (4) coexisting pulmonary or cardiovascular disease in which cases a gastro-enterostomy may be ill advised. Other causes of disappointing results are: (1) a young patient, (2) a short and atypical history, (3) the "constitutional inferiority" type of individual, (4) a small ulcer without obstruction, (5) bad habits of living, and (6) technical errors at the time of operation. Failure to recognize the cases in which a disturbance of motor function of the upper gastrointestinal tract results in severe toxemia is a cause of an unnecessary mortality in this group of cases.

Sherren reports that the persistence of high acids after gastro-enterostomy is intimately connected with the production of ulcer.

In closing, the writer states that at present there is no conclusive evidence that there is any operation more useful than gastro-enterostomy in cases of duodenal ulcer and also that the gastro-enterostomy can be disconnected with ease and safety after the ulcer has healed, if desired.

DONALD K. BACON,
LOWRY BLDG., ST. PAUL
VERNE C. HUNT,
MAYO CLINIC, ROCHESTER

THE PRESENT STATUS OF THE SURGICAL TREATMENT OF CHRONIC DUODENAL AND GASTRIC ULCER: Chas. H. Peck (Ann. of Surg., July, 1924). The success of the gastro-enterostomy to relieve symptoms lies in the fact that the irritating character of the stomach con-

tents becomes less and that it short-circuits the stomach contents and permits healing of the ulcer.

Chronic gastric ulcers should be managed differently than ulcers of the duodenum. The eradication of the ulcer should be a part of the operative procedure.

If the ulcer is near the pylorus, the author favors excision or destruction of the ulcer by the actual cautery, then to proceed with a gastro-enterostomy.

In gastric ulcers with marked inflammatory reaction, adhesions, and a patient in poor condition, it is sometimes advisable to make a gastro-enterostomy and a second stage for resection, if necessary.

Mid-gastric ulcers will frequently respond better to a trans-gastric resection than to a gastro-enterostomy.

In chronic ulcers of the duodenum and stomach, the choice of operation is very important and depends largely upon the type of ulcer; hence the author has divided them into four general classes.

1—Single anterior ulcers of the duodenum which may be treated by local excision.

2—Chronic indurated ulcers without obstruction, single, multiple and perforating, and most of these respond to the simple gastro-enterostomy.

3—Chronic ulcers with obstruction and in these gastro-enterostomy is the operation of choice.

4—Cases with severe hemorrhage, and these are frequently cured by gastro-enterostomy, although in some cases it is necessary to excise the ulcer.

Radical resection should be reserved for cases with:

1—Inflammatory mass or suspected malignancy

2—Cases complicated with gastro-jejunal ulcer (2 per cent)

3—No relief of symptoms following gastro-enterostomy

Success in gastro-enterostomy depends largely on surgical technique and the author's technique is described in detail.

L. D. POWELL.

APPENDICEAL FECAL FISTULA: J. B. Deaver (Ann. of Surg., July, 1924). In this article the author discusses the occurrence of fecal fistula in cases operated upon for acute appendicitis. In the Lankenau Clinic, appendicitis is grouped acute or chronic, since they find that practically all cases of acute appendicitis are partially or entirely gangrenous. If the gangrenous area is large, the patient frequently has a chill. A chill may also be due to thrombophlebitis of the veins of the meso-appendix and of those into which they drain.

Fecal fistula complicates appendicitis in the cases presenting perforation, abscess and drainage. There were 200 cases of fistula in the last 4,063 cases of acute appendicitis, or 5 per cent. In every case pus was present, requiring drainage. Cases showing perforation at the base showed a tendency to fecal fistula formation, owing to the amount of inflammatory reaction and the friability of the tissues relied upon for turning in the stump.

Of the 200 fistulae, 74, or 37 per cent, healed spontane-

ously; 97, or 48.5 per cent, required operative repair. The remaining 29 per cent either refused operation or failed to return for operative repair, having been sent home to recuperate. A period of trial for spontaneous closure was given, depending upon the patient's physical condition.

The type of operation depended upon the existing conditions. In 60 per cent of the cases, simple inversion of the fistulous opening by a purse-string linen suture reinforced by an additional suture line was sufficient. In 15 per cent, ileocolostomy was performed after inversion and reinforcement of the fistula. This was done in the cases where the regenerative power was doubtful. Twenty-three per cent presented either multiple fistula or else the fistula was so large as to preclude closure with maintenance of the lumen. In these resection of the bowel was done and an anastomosis performed.

Eighty of the 97 operated cases recovered and were discharged healed. In eight cases the fistula recurred and nine died after operation. Only 37 per cent of the entire series healed without surgical repair.

F. A. BOTHE.

THE TREATMENT OF ACUTE MECHANICAL INTESTINAL OBSTRUCTION BY TEMPORARY JEJUNOSTOMY: Walter Estell Lee and T. McKean Downs (Ann. of Surg., July, 1924). The seriousness of acute mechanical intestinal obstruction has been recognized for years and known to carry a very high mortality, which is not alone due to the obstruction but to the absorption of toxic material generated in the duodenum, probably from the pancreatic and biliary secretions.

The treatment therefore in these cases must be:

1—Remove toxic material as early as possible.

2—Relieve the distended bowel of its contents, which are paralyzing its musculature.

3—Restore the continuity of the intestinal lumen.

The extent of the surgery to be done depends upon the time the obstruction has been present, cases within twenty-four hours having good chances by relief of the obstruction alone; but cases of several days' duration have a paralytic condition of the intestine as well as the obstruction, so therefore it is better to simply do a high jejunostomy after the method of Witzel, which places a soft rubber catheter into the distended loop. This is done by means of purse-string and then the catheter carried along the gut for two or three inches in a trough-like groove and the serous coats of the intestine brought together over the catheter. After the jejunostomy has been completed, the obstruction proper may be treated if the patient's condition permits, and if not, the release of the mechanical factors may be done as a second stage.

The opening in the jejunum is carried up to and stitched to the parietal peritoneal and after the obstruction is overcome and the tube removed, the opening closes without danger of fistula or other complications.

The contra-indications are practically nil.

ROY N. ANDREWS,
MANKATO CLINIC, MANKATO

MANAGEMENT OF SUMMER DIARRHEAS IN CHILDREN: Carroll M. Pounders (Arch. of Ped., August, 1924): The annual mortality from the diarrheal diseases in children under two years of age exceeds the combined mortality from measles, scarlet fever, pertussis, typhoid and diphtheria at all ages. Artificial feeding is probably the most important single etiological factor. Less than five per cent of the severe cases occur among breast-fed babies and a fatal case is rare in a baby on the breast. The author's greatest difficulty during the summer months is with fermentative and infectious diarrheas.

Fermentative diarrhea is simply a fermentation of the intestinal contents without any attack on the mucosa or other body tissues by the causative organisms. Infectious diarrhea is a definite bacterial invasion of the intestinal walls and other body tissues by some strain of the bacillus dysenteriae. The condition really should be called bacillary dysentery. In the fermentative type, the abdomen is commonly distended, but there is little pain or tenesmus. In the infectious type, the abdomen is usually flat or sunken. There is often pain and tenesmus and there may be tenderness to pressure along the colon. The character of the stools is different. In the fermentative type, there is usually a green, watery, irritating stool, acid to litmus and showing fermentation. The infectious type of stool is characterized by the presence of pus and blood, very little odor and an alkaline reaction.

The treatment can be discussed under the following headings: (1) initial purgation—that is: oil or magnesia; (2) period of starvation—12 to 24 hours; water freely. This can be given as plain water, barley water or weak tea, preferably barley water, sweetened with saccharin.

Diet: In the fermentative type, the prevalent organisms thrive on a carbohydrate medium. So a food that is high in protein and containing a minimum of fats and carbohydrates is indicated. These requirements are well met by protein milk. It is more readily taken when sweetened with saccharin, using one grain to each quart. The child can be kept on this for some time. When the number of bowel movements approaches the normal, the protein milk can be gradually replaced by boiled skimmed milk. The fats should be withheld for weeks afterwards, as they are very poorly tolerated. In the infectious type, showing blood in the stools, we are dealing with some strain of the dysentery bacillus. Moreover, an excess of carbohydrates tends to inhibit their growth and development. So the indication is distinctly for food composed of carbohydrates and containing very little, if any, fats or proteins. Lactose is the

carbohydrate of choice, as it is slowly broken down and is more apt to reach the lower intestinal tract. It is given in a 7 per cent solution. In from one to five days more, depending upon the amount of improvement, small amounts of boiled skimmed milk are cautiously added. This is carefully raised until it replaces the sugar solution. Cream of wheat can be added quite early.

Toxemia, temperature, dehydration and acidosis: Obviously, the indication is to restore the fluid balance. In mild cases, where there is no vomiting and very little diarrhea, sufficient fluids may be given by mouth. More severe cases are controlled by administering normal saline subcutaneously. But if it becomes necessary to give very much fluid, other than by mouth, the intraperitoneal or intravenous route are more satisfactory.

Drugs play a very small part in the treatment.

R. N. ANDREWS,
Mankato Clinic, Mankato, Minn.

EXPERIENCES WITH LACTIC ACID MILK IN INFANT FEEDING: Morris Gleich (Arch. of Ped., August, 1924). Lactic acid milk, in the absence of breast milk, furnishes an excellent substitute for the routine feeding of well and sick babies. Healthy and sick infants, fed lactic acid milk, have peptic digestion to a certain degree. Acid, then, added to cow's milk renders it favorable to peptic, rennin and lipase digestion.

In the preparation of acid milk the method described by Marriott and Davidson was used. One teaspoon of lactic acid (U.S.P.) is added, drop by drop, to a pint of sweet whole milk, which is previously boiled 5 minutes, the scum removed, and allowed to cool. Two tablespoons of karo syrup are then added. In preparing lactic acid milk, the author suggests that a glass rod be used instead of a spoon and that stirring be very slow. It is advisable to stir about six times to every drop of lactic acid added. A tall vessel seems to give finer curd than a flat pan.

A study of lactic acid milk feeding was made in order to note its value and compare results with other methods. The stools were always soft, yellow and pasty, and had no offensive odor. No mucus or blood was observed. In fact, all children were remarkably free from gastrointestinal disturbances. Abdominal distention, present in three children, caused no apparent discomfort.

The high caloric value of lactic acid milk can be best appreciated by considering a sweet milk formula. If a child of 3 months, weighing 11 pounds, takes 19 ounces sweet whole milk, 11 ounces water and 3 tablespoons dextrimaltose, 5 ounces q3h, it received 500 calories. If that same child is fed 5 ounces lactic acid milk q3h its intake is 840 calories (1 qt. 1 a. m. 600 calories plus karo syrup 4 tablespoons, 240 calories).

Conclusions: Lactic acid milk in infant feeding is no panacea. It has a valuable place in the armamentarium of the pediatrician. Lactic acid milk may probably replace protein milk in the severe diarrheas of infancy. By increasing gastric acidity, it may play an important role in the prevention and treatment of rickets and tetany.

R. N. ANDREWS.

NEW EVIDENCE ON CALCIUM THERAPY IN TUBERCULOSIS: (New York Intravenous Laboratory, 100 West 21st Street, New York).

The value of calcium in tuberculosis has been the subject of much debate. On one hand existed the opinion of the practitioner, based on isolated cases. On the other, and opposed to it, was the academician, who, by animal experiments, was unable to demonstrate the clinical effect claimed by the practitioner. A few clinicians were inclined to believe in the value of calcium, but were unable to demonstrate sufficiently uniform results to enable them to come to definite conclusions as to its value.

This state of knowledge of the value of calcium is not unique in therapeutics. The same condition exists as to the value of other remedies, used empirically and administered by mouth.

A change of opinion as to the value of calcium has been brought about by the intravenous administration. Loeser, in his research work with a number of U. S. P. and standard remedies, ascertained that Calcium Chloride and Calcium Guaiacol Sulphonate, and other calcium salts are adaptable to intravenous administration.

Since the standardization and the commercializing of Loeser's Intravenous Solution of Calcium Chloride, many practitioners and a number of clinicians have proved conclusively that calcium is of great value in tuberculosis. During the last three years an increasing number of articles have appeared in the J. A. M. A. and in other medical journals on the subject. The American Review of Tuberculosis published in their April Number an article on Calcium Chloride in tuberculous enteritis. This is a report of clinical work done in the Fitzsimmons General Hospital, Denver, Colo., and was published by permission of the Surgeon General.

THE CONTRA-INDICATIONS TO RADIUM IN THE TREATMENT OF DISEASE OF THE FEMALE PELVIS: F. E. Keene (Amer. Jour. of Ob. and Gyn., August, 1924). The author discusses the contra-indications to radium in the treatment of diseases of the pelvis. Except for a few broad statements, this paper is confined to benign lesions.

Two facts stand out in observation on these cases: (1) In properly selected cases the advent of radium marks a great epoch of advance in the realm of gynecological therapeutics. (2) A sharp dividing line exists between the types of cases suitable for radiation or operation.

In dealing with cancer of the cervix early operation supplemented by irradiation is the method of choice. In advanced cases, especially those with extension, it is thought

unwise, as even palliation cannot be hoped for, and irradiation may add suffering to the patient's already miserable condition. What a combination of radium and deep x-ray therapy offers is still an open question. While only early lesions of the cervix are operated upon, operation is employed in fairly advanced fundal carcinomata applying radium ten and fourteen days later.

In discussing the contra-indications to radium in benign lesions, the remarks are limited to cases of myomata and so-called myopathic hemorrhages.

The contra-indications are:

1—*Tumors larger than three months pregnancy.*

Frequently adnexal and intestinal pathology and extensive degenerative changes are found and the already limited blood supply further impaired.

2—*Rapidly growing tumors suggesting sarcoma or actively progressing benign changes.*

3—*Uncomplicated tumors of any size giving rise to symptoms other than abnormal menstruation.*

Symptoms are usually mechanical in origin as a result of traction or pressure and the tumor disappears too slowly to justify radium therapy.

4—*Tumors associated with pelvic pain.*

Operation is preferable here because the pain is usually due to adnexal disease, usually inflammatory; to degeneration within the tumor or to adenomyomata. Radium excites old pelvic inflammatory conditions and degenerative changes or adenomyomata do not respond favorably.

5—*Pedunculated tumors whether subperitoneal or intra-uterine.*

Radium is useless here.

6—*Tumors producing hemorrhage and complicated by demonstrable adnexal pathology.*

7—*The presence of a marked secondary anemia in association with tumors not giving rise to sufficient uterine bleeding to account for the anemia.*

In the three cases observed necrosis of the tumor was found and rapid disappearance of the anemia post-operative.

8—*Tumors in young women.*

Radium sufficient to cause disappearance of the tumor may bring on a menopause and sterility. Doses are justifiable and sometimes beneficial in myopathic hemorrhages.

9—*Tumors so distorting the uterine cavity that introduction of radium well above the internal os is impossible.*

Sufficient radiation of the uterus is impossible and subsequent contraction of the internal os may give rise to hematomata or pyometra. Furthermore, a diagnostic D & C is indicated to rule out an area of malignancy.

10—*Where differentiation between myomata and adnexal pathology cannot be definitely determined.*

11—*Myomata or myopathic hemorrhage in nervous women.* Menopausal symptoms are probably more acute following irradiation, if they develop, and it is very likely to be the case in nervous women.

12—*In cases of radiophobia.*

EFFECT ON THE BLOOD OF IRRADIATION: Minot and Spirrling (Am. Jour. Med. Sci., Aug., 1924). An unusually complete review of the literature is presented together with the results of blood studies on 42 cases of malignant disease receiving various doses of roentgen rays. The effects of both deep and superficial therapy are presented and compared.

The most important findings are:

1. The first effect of radiation is a transient increase of neutrophiles. Following this a leukopenia and lymphopenia develop, the count going below 5,000 frequently about 6 days after intensive therapy. Bone marrow depression is present at this time.

2. The character of the reaction following the newer deep therapy is the same as that following more superficial doses, but it comes on more rapidly, is more intense, and more persistent.

3. Eosinophilia, degenerated leucocytes, and an increase of immature leucocytes appear frequently. Platelets are only slightly affected while there are no important changes in the red corpuscles or the hemoglobin.

4. The clinical condition of the patient is much less

important in producing the reaction than the character of the dose. The amount of surface area radiated is of great importance in determining the amount of blood changes which will take place.

5. Although a moderate depression of activity of lymphatic tissue and bone marrow do not have any serious detrimental effects, care should be exercised to determine the degree of leukopenia before radiation and where a study of the formed elements of the blood indicates a severe marrow depression it may be well to consider whether the benefits to be derived from further radiation will offset the disadvantages of increased hemopoietic depression.

LEO G. RIGLER.

MASSIVE COLLAPSE OF THE LUNG: Holmes (Am. Jour. Roent., June, 1924). The most important roentgen findings are as follows:

1. Displacement of heart and mediastinum to the affected side together with a high rigid diaphragm. This may occur in chronic fibrosis of the lung, but the appearance of the affected lung should indicate the diagnosis.

2. Lung in affected area gives a gray mottled shadow with loss of outline of the diaphragm if the lower lobe is involved.

3. The findings simulate collapse of the lung from other causes and the history is necessary to make the definite diagnosis.

Four cases of massive collapse following operation are reported with roentgenograms at different stages of the condition.

LEO G. RIGLER.

THE MINNEAPOLIS GENERAL HOSPITAL offers a Technician's Course in x-ray to women having high school diplomas. Course covers a period of eight months. Diploma is issued upon completion of the course. Noon meal furnished. Address Minneapolis General Hospital, Minneapolis, Minn.

FOR RENT—Two fully equipped offices in the Physicians and Surgeons Building, Minneapolis. Use of laboratory, operating room and reception room for morning hours. Nurse in attendance. Address C-5, care MINNESOTA MEDICINE.

PHYSICIAN'S OFFICE FOR RENT—Hamm Bldg., St. Paul. Centrally located. Dental office in connection, with furnished reception room. Reasonable. Call Cedar 2460 or address C1, care MINNESOTA MEDICINE.

MINNEAPOLIS OFFICE SPACE TO SUBLET—Very desirable office space at 323 La Salle Bldg., Minneapolis, to be sublet by Drs. Willson, Cabot and Wohlrabe. For information call at office or telephone Main 3220.

PRACTICE FOR SALE—General practice in northwest central Minnesota, in town of 600. Prosperous farming and dairying community. No competition; \$6,000.00 cash business last year. Will sell for price of equipment. Good reason for selling. Address C-8, care MINNESOTA MEDICINE.

FOR SALE—Stearns-Knight four-passenger militaire in perfect condition—cheap for cash. Tallant, 116 South Sixth Street. Atlantic 5721.

WANTED—Position as record clerk or office assistant in hospital or clinic. Knowledge of stenography. Can also do routine laboratory tests. Address C-6, care MINNESOTA MEDICINE.

EXCELLENT opening for physician at Bagley, Minnesota. No other practicing physician within radius of thirteen miles. For particulars address E. R. Wright, Bagley, Minn.

MINNESOTA PHYSICIAN desires to dispose at once of his nearly new drug stock at half cost price. Address C-7, care MINNESOTA MEDICINE.

THE BEHAVIOR OF THE TESTIS UNDER VARYING EXPERIMENTAL CONDITIONS AND THE FUNCTION OF THE SCROTUM; TRANSPLANTATION, CRYPTORCHIDISM, VASECTOMY*†

CARL R. MOORE, Ph.D.
Chicago

In the department of Zoology at the University of Chicago we have been engaged for the past six or seven years on a relatively intensive program of sex research. This has been to a large extent an outgrowth of the beautiful work of Prof. F. R. Lillie, chairman of the department, who demonstrated that fetal hormones have a remarkable capacity of influencing the sexual development of a growing fetus. This work, done on the developing twins of cattle, showed that a male-female combination resulted in the male delivering certain substances that not only prevents the proper development of the reproductive system of the female but even influences its development in a remarkable manner towards the male type. Our procedures have been directed toward an analysis of the primary question of sex and my own part of it has been directed to a biological study of the sex glands. Today I shall touch upon but one of the many sides of the work—namely some of the biological aspects of the mammalian testis. Presented largely from the biological aspect I will purposely leave to you for the most part the clinical applications that underlie and run through the work.

TESTIS GRAFTS

Probably the best known work in this field comes from the laboratories of Steinach in Vienna,

†From the Hull Zoological Laboratories, the University of Chicago.

*Presented before the Minnesota State Medical Convention, St. Cloud, Minn., Oct. 10, 1924. References to authors quoted and some details here omitted will be found in a paper of similar character in the *Journal of Endocrinology*, vol. 8, No. 4, 1924.

Sand at Copenhagen, and Lipschutz at Dorpat. Briefly, the typical testis graft—a whole or a part of a testis transplanted from one individual to another and recovered some months later—is somewhat different from normal testis tissue (Fig. 1). The seminiferous tubules are characteristically devoid of a germinal epithelium and though well outlined, but considerably smaller in diameter than normal tubules, contain but a single layer of cells next the basement membrane; these cells are ordinarily thought to be sertoli cells. The seminiferous tubules, unlike those of normal testes, are widely separated from each other, the intervals being packed with interstitial tissue. It is the latter tissue that is usually considered to be the internal secretory tissue of the gland.

Personally I have obtained many grafts from the rat and guinea-pig transplantations resembling

Fig. 1. Part of cross section of testis graft from female guinea-pig, seven months after transplantation, *ic*, interstitial tissue; *st*, degenerate seminiferous tubule.

this grade of graft but it has been the unusual type that has been of most importance from the fact that it presents conditions to be accounted for and has thus stimulated further work.

It should be mentioned that testis grafts have

been recovered from transplantations into normal males, castrated males, normal females, spayed females, and females that have given birth to normal litters of young while carrying the testis graft; these have been recovered from thirty days to approximately one year after transplantation. It is perhaps known to many of you that a considerable amount of Steinach's work and theories postulate an antagonism between the sex hormones derived from the ovary and testis. He has emphatically stated many times that this antagonism is of such a nature that one sex gland will not grow or persist in the presence of the other. My own work is in entire disagreement with this idea and I have produced artificial hermaphrodites, experimentally, so that a functional female would carry a testis graft or a functional male carry an ovarian graft that was actively maturing new follicles. It is also known that human material presents occasionally a fair degree of typical hermaphroditic glands that have persisted for long periods of time.

But this unusual type of graft I have obtained demands our attention. Instead of degenerate, quiescent seminiferous tubules and a great interstitial cell hypertrophy, some of them have contained seminiferous tubules in an active stage of spermatogenesis with normal amounts of interstitial tissue (Fig. 2). The sex cells have continued to multiply, building up an epithelium of two to three cells in thickness, but the innermost cells fail to adhere to those being produced underneath, and become loosened from the epithelium, escape into the lumen of the tubules, and degenerate. It is a curious fact that out of the hundreds and literally thousands of testis grafts that have been studied from mammals no one has ever found a graft in which complete germ cell differentiation has taken place, whether the graft was made subcutaneously, intra-muscularly or intra-peritoneally. It has been a problem since the first graft was studied to account for the complete absence of spermatozoa; active multiplication of these germinal cells goes on but none ever reach the final stage of the flagellate spermatozoon. One of our problems has been to determine why it is so.

Our first step in advance in obtaining real information on this question came through a study of experimental cryptorchidism. It is common knowledge that man and many other mammals (pig, horse, sheep, etc.) occasionally experience a

retention of one or both testes in the abdominal cavity; one in 500 military recruits according to Dr. Bevan of Chicago. One or both testes fail to descend into the scrotum through the inguinal canal and since hidden from view are known as "cryptorchid testes." Many such have been described and they are invariably abnormal and functionless so far as sperm production is concerned; doubly cryptorchid men or animals are sterile. The seminiferous tubules are without an epithelium similar to the ordinary testis graft.

It has usually been assumed that the condition of these undescended testes was due to an improper embryological formation but that this is wrong I will show unmistakably.

The guinea-pig, rat, rabbit, and some other mammals retain throughout life a wide open connection between the scrotum and the peritoneal cavity, and the testes may be elevated through the

Fig. 2. Part of section of testis graft from female guinea-pig nine months after transplantation. *a*, cells of germinal epithelium free in tubular lumen; *ic*, interstitial tissue; *st*, seminiferous tubule with many cells in germinal epithelium.

open inguinal canals into the abdominal cavity, to redescend into the scrotum on relaxation of the controlling muscles. Under these conditions the testes are normal. If, however, the testes are pushed through the open inguinal canals into the peritoneal cavity and are prevented from returning to the scrotum a very rapid and striking, progressive degeneration of the generative portion follows. Forcible retention may be accomplished by several slightly different means, i. e., by severing the mesenterial connection between the epididymis

and the bottom of the scrotum and turning the testis back into the peritoneal cavity; by pushing the testis through the canals and tying the scrotum, or sewing shut the inguinal canals, etc. Under such conditions the blood supply, nerve connections and vas deferens are normal. More certainly will the testis be retained in the abdomen if the inguinal canals are closed with a purse string suture, but in approximately 50 per cent of the cases in the guinea-pig the testes do not redescend into the scrotum when the canals remain open, even though the testes are not fastened by sutures.

It makes little difference what means are taken to insure abdominal retention of the elevated testis, the results are the same if the organ does not sag into the inguinal canal. The germinal epithelium of a normal active testis retained for the short period of seven days in the abdomen will be found to be totally disorganized. The usually well defined tubular lumen will be practically filled with a mass of free cells thrown out from the epithelium; many cells may appear approximately normal but the majority are in a stage of degeneration. Some of the cells can be defined in outline only, others show fragmentation of the nucleus, and chromatin materials scattered throughout the cell or protoplasmic masses may be located in a granular debris, the result of more extensive degeneration. The former compact epithelium is little in evidence, its place having been taken by a fibrillar reticulum filled with vacuoles or spaces from which the cells have escaped or in which they have undergone fragmentation and dissolution, with or without the complete removal of the fragmented remains. Very often large multinuclear protoplasmic masses—typical “giant cell” like masses—are to be found either in the epithelial position or loose in the lumen. All stages in the formation of these multinucleate masses can be followed and they are seen to owe their origin to the coalescence of contiguous germinal cells; the cell walls disappear and the epithelium reminds one of the proverbial melting pot in which discrete cells are merged into a common protoplasmic mass.

By fourteen days peritoneal retention the majority of the degenerating debris has been removed from the tubules through liquefaction and transportation and but few cells can be seen; these are almost without exception in a degenerate condition. By twenty days little else remains in the tu-

bules, aside from the reticulum, than the Sertoli cells situated against the inner border of the basement membrane, and a few spermatogonia. We have, therefore, produced experimentally, within twenty days, a typical cryptorchid testis such as occurs in nature.

So long as the testis remains in the peritoneal cavity it is degenerate. (See Fig. 3.) Followed at brief intervals from seven days to more than a year after operation, the testes are found to progressively decrease in size; tubules shrink to one-third their original diameter and interstitial cells become more prominent and are collected in masses between the now more widely separated tubules. If by chance the testis returns to the scrotum after being elevated into the peritoneal cavity it may be found a few months later in a normal condition. If descent has been only partial, and the testis is held by adhesions from taking its normal scrotal position, then the testis may be in part normal, part degenerate. In general it may be stated that the more nearly a testis returns to its normal scrotal position the more nearly normal will be the seminiferous tubule epithelium.

To test the powers of recuperation of a testis after degeneration, both testes of an animal were elevated to the peritoneal cavity and so retained for

Fig. 3. Seminiferous tubules from testis of adult sheep retained in abdominal cavity for 76 days. Germinal epithelium has been removed and Sertoli cells remain in the tubules.

twenty-four days. By a second operation one testis was replaced in the scrotum, the opposite one removed and studied histologically to ascertain the stage of degeneration of the one in the scrotum. The seminiferous tubules, at the end of twenty-four days are empty of all degenerating re-

mains, and Sertoli cells with a small number of spermatogonia formed a single layer of cells against the walls of the basement membrane.

It can be realized, therefore, that the testis replaced in the scrotum, after its twenty-four days retention in the abdomen, was in a highly degenerate condition. It was allowed to remain in the scrotum for two and a half months when the animal was killed and the testis prepared for histological study. The replaced testis had almost completely recovered from its degenerate condition. The majority of the tubules contained a well established epithelium and in many of them spermatozoa had again appeared. A few tubules were in stages of partial recovery but some were entirely devoid of an epithelium. In the latter case it is questionable if recovery would have ever taken place and there is little doubt that all cells capable of further division were destroyed during the peritoneal confinement. The few totally degenerate tubules were located indiscriminately among normal tubules and not segregated off into any particular locality, thus showing that recovery has no definite relation to particular local conditions within the gonad but depends upon the presence of cells capable of further division at the time of scrotal replacement.

It follows, therefore, that the scrotum exerts a peculiarly striking influence upon the testis and an influence that is necessary not only for the complete differentiation of germ cells but even for the retention of cells previously differentiated. Removed from the scrotum, or from conditions simulating those of the scrotum, a testis is rapidly deprived of its germinal epithelium.

Is this not a partial solution for the absence of normal tubules containing spermatozoa in testis grafts? With a realization that the testis-scrotal relationship was necessary for the production of spermatozoa I transplanted testes into the scrotum by sewing them to the walls of the tunica vaginalis. Though the tunica vaginalis would seem a rather poor place for the development of the necessary vascularity for a graft to persist, nevertheless the transplantations were successful and grafts have been recovered six months after transplantation that contained normal seminiferous tubules with typical spermatozoa. Thus for the first time have testis grafts from mammals been obtained that contained normal seminiferous tubules. We have additional evidence in this result that the scrotum is

necessary for germ cell differentiation in those mammals that normally possess a scrotum.

THE STEINACH OPERATION

Looking at the problem of the biology of the sex gland from another angle the popularly known and, if you will pardon an academic opinion, the too frequently practiced Steinach operation has come in for considerable attention in our laboratory. This problem of vasectomy or vasotomy has been a battleground of opinions for more than fifty years. It involves the effect upon the testis of occluding the vas or ductus deferens, the outlet duct of the testis. Opinions have been about equally divided that such an operation causes the generative part of the testis to atrophy and the supposed internal secretory part to undergo an increase, and that it leaves the testis normal. The French writers, Bouin and Ancel, who are really the founders of the conception that testicular hormones are the products of the interstitial cells, gave this problem its initial impetus, and following the recent work of Steinach the debatable condition has in the last few years been elevated to the position of one of the twentieth century miracles. It is at once a means to rejuvenate a worn-out organism and restore its youthful qualities, to enhance a pugnacious temperament, cure failing eyesight, headaches, heart-failure, and regulate blood pressure—truly a phenomenal series of results from such a simple procedure as the ligation of the excurrent duct of the sex gland.

Let me make my position clear that clinical symptoms have played no part in my results, since it is sometimes difficult to adequately determine the feelings of a rat or guinea-pig. It is also too well known that with a certain class of people in the proper mental conditions the mere acquaintance with the mysteries of an ether anesthesia works wonders untold. My own interests in the problem have been purely biologic and my first operations in 1919 were done to study the testis reactions and not to disprove the contentions of other workers.

The previously described results, and the philosophy accompanying the same, in brief, is that occlusion of the ductus deferens causes a rapid degeneration of the germinal epithelium accompanied by an increased amount of interstitial cells. These interstitial cells are therefore supposed to furnish an overabundance of internal secretions or

hormones, and these substances are the effective and sought-after results of the operation. This reaction is the only morphological evidence upon which the end results are based and upon the behavior of the tissue must stand or fall the value of the operation.

I could dismiss the results with a word were it not essential to attempt to harmonize the very divergent results obtained after the operation, and to attempt an explanation of the primary misconception.

I have performed the experiment on rats, guinea-pigs, rabbits and sheep and the results are consistent in showing that the operation leaves the testis in a normal, functional condition, actively producing germ cells, provided that it retains its normal position in the scrotum. Since the rabbit has been used to a great extent for such operations let me review, very briefly, the series of experiments brought to a close late in the past summer. It has been maintained that degeneration in the testis after vas deferens occlusion occurs from two to three weeks after operation.

Mr. Quick and I did twenty operations and studied the testes carefully at two weeks, one, two, three, four, five, and six months later. We found that the generative portion shows absolutely no reaction to the operation but the testis continues to produce germ cells. Not in a single case in all my vasectomy operations, on any of the four groups of animals, has there ever occurred an interstitial cell hypertrophy. And kindly remember, please, that it was only on the basis of such an hypertrophy that the idea was ever conceived. In the rabbit six months after vasectomy the testes have been found to be actively producing germ cells. In fact the intensity with which this proceeds even causes the epididymis to increase in size in order to accommodate the testis products.

Is it possible, from what we now know, to account for these findings of Bouin and Ancel, Steinach, Sand, and others?

I believe that many of the positive findings, for instance the degeneration which took place in the testis after vas ligation, can be explained on the basis of an abnormal testis-scrotal relationship. Following the operation on animals with open inguinal canals adhesions often cause the testis to be partially or completely drawn into the abdomen. Dr. Oslund, working in our laboratory on rats and guinea-pigs, performed something like 75 opera-

tions very diversified as to the time the testes were allowed to remain in the animal after operation. Many of these testes were degenerate, but in every case this degeneration was correlated with an abnormal relationship of the testis to the scrotum. If this organ is displaced towards the abdominal cavity we can only expect degeneration—but this is not caused by the vas deferens having been occluded.

In an adult rabbit I purposely displaced one testis and fastened it in an abnormal position with relation to the scrotum but left the vas deferens alone, whereas its partner remained normal with relation to the scrotum but had the vas deferens ligated and cut in two parts between ligatures. After two weeks the vasectomized testis was perfectly normal but the displaced one was highly degenerate; it must be remembered that in this instance, where the vas deferens was normal, degeneration was marked. This shows the misleading possibilities had the vas deferens in both cases been ligated.

When the epididymis, located for the most part at the bottom of the scrotal sac, increases so greatly in size after vas ligation, it pushes the testis upward into the inguinal canal or indeed through the canal into the abdomen. We have obtained degeneration in such cases, as is to be expected, but again it is not due to vas occlusion.

May I emphasize, therefore, that on the most carefully conducted type of operation, I can find no biological justification for the ideas underlying the Steinach operation.

Here again, however, we have re-emphasized the importance of the normal testis-scrotal relationship. A testis displaced from the scrotal influence rapidly undergoes degeneration, whereas its partner residing in its normal position remains healthy and active. What is this mysterious relationship that exists between testis and scrotum?

A few years ago I set about to attempt an answer to this question, and eliminated by experiment every possibility occurring to me but one and stated in 1922 that it appeared to be a temperature factor—a differential temperature between the body and scrotum. While working upon experiments to prove or disprove the hypothesis I came across a paper from the laboratories at the University of Edinburgh by F. A. E. Crew, who offered the suggestion on purely hypothetical grounds that a differential body temperature might account

for the structural condition of undescended testes.

Now if it is a differential temperature factor that is the underlying cause of degeneration several corollaries should follow. In the first place the temperature within the scrotum should be lower than that within the abdomen, and in such a case it would be recognized that the scrotum was a local temperature regulator for the testes. Then, could we prevent the scrotum from functioning in this regulatory capacity, the testes should show degeneration without displacement from the scrotum. This latter possibility was tested first.

SCROTAL INSULATION

With the cooperation of Dr. Oslund, the scrotum of a ram was insulated against loss of heat by securely, though loosely, encasing it in woolen materials and a water-proof covering, sewed to fit the scrotal contour, and suspended sufficiently by arti-

retained testes, while many tubules lacked entirely the germinal epithelium (Fig. 4). *The animal had sterilized itself with its own body heat due to prevention of the local thermo-regulatory function of the scrotum.*

SCROTAL TEMPERATURE AND BODY TEMPERATURE

With Mr. W. J. Quick, temperature readings were made with ordinary thermometers passed into the abdomen through locally anesthetized abdominal regions of rats, rabbits, and guinea-pigs. One thermometer bulb in the peritoneal cavity and another passed through the open inguinal canal into the scrotum, alongside the testis, showed us that at the same moment the scrotal temperature was appreciably lower than that in the peritoneal cavity in all cases. The differences between the two cavities varied as the external environmental temperature varied (Figs. 5 and 6). Thus in a white rat observed in a room temperature of 16° C. the scrotal temperature was 8° C. lower than that of the peritoneal cavity. This gives absolute proof, therefore, that the normal environmental temperature of the testes is appreciably lower than the general body temperature.

There remained for disposal one further assumption to provide actual proof of the correctness of our working hypothesis, namely, the testis should undergo degeneration following the application of temperatures slightly higher than those normal for it.

EFFECTS OF HEAT

It was found that hot water pads applied to the external surface of the guinea-pig scrotum, raising the temperature approximately 6° to 7° C. above normal body temperature for a period of fifteen minutes resulted in severe tubular degeneration within ten days after application. Increasing or decreasing either the length of application or the degree of temperature applied we can produce at will any stage of degeneration desired from the destruction of a few peripheral tubules to complete degeneration of all seminiferous tubules in the testis. Direct submergence of the testis in a controlled saline bath of 47° C. for five minutes is sufficient to produce complete degeneration of every tubule of a guinea-pig testis within five days after the application. Thus the application of slightly higher than its normal temperature is shown to be fatal to the generative portion of the testis and the degeneration following such an application is very

Fig. 4. Portion of testis of adult sheep 80 days after scrotal insulation (no other operation). *dp*, tubule in stage of degeneration with debris of former germinal epithelium in lumen; *it*, interstitial tissue; *stc*, seminiferous tubules devoid of germinal epithelium.

ficial supports as to preclude binding the scrotum or producing abnormal pressure. Within eighty days the testes were found to be devoid of spermatozoa; many tubules were in advanced stages of degeneration, the tubules being filled with loosened, degenerating cells similar to peritoneally

similar to the type occurring after testis elevation into the peritoneal cavity.

The totally independent work of Fukui, a Japanese investigator, but recently published, arrives

Fig. 5. Graphs showing temperature of abdominal cavity in comparison with temperature of scrotum in the rabbit and guinea-pig, at different room temperatures. In each case (Fig. 6 also) the abdominal cavity temperature is indicated by a solid line. At point A, one thermometer pushed into scrotum alongside testis; decline in temperature indicated by dotted line. At point B, scrotal thermometer retracted into abdomen; temperature curve ascends.

at a similar interpretation with respect to the effects of temperature on the testis and the explanation of degeneration of testes elevated into the body cavity. Applying heat in the form of hot water, hot air, heat of the sun, and arc light heat, Fukui has worked out a so-called "heat curve" of the testis in relation to time of application and degree of temperature employed. A very striking observation, however, and one that greatly strengthens our proof of degenerate testes when elevated into the body cavity was made as follows: Fukui elevated both testes of an animal into the peritoneal cavity but artificially cooled the external area on one side in the region of the elevated testis. He found that in the course of a few days the testis in the artificially cooled area was normal, whereas the uncooled testis was highly degenerate. Thus with all

the accumulated evidence there should no longer be any doubt that our conception of the effects of the body temperature on the testis condition is the correct one.

Let us examine briefly, then, the qualifications of the scrotum as a local thermo-regulator for the testes. In its simple form in the rodent the scrotal sac is but an outpouching of the peritoneal cavity posteriorly underneath an area of skin much thinner than ordinary skin, and well provided with sweat glands; the muscular layers are exceedingly

Fig. 6. Graphs showing abdominal cavity temperature in comparison with scrotal temperature in the white rat, at different room temperatures. Procedures and temperature changes indicated as in Fig. 5.

thin; subcutaneous fat is absent, and the organ varies in size and shape as environmental temperatures vary. Thus on hot days the scrotum relaxes to its full pendent condition, permitting the testes

to be farther removed from the body, whereas in a cold atmosphere the scrotum is contracted bringing the testes nearer to the body. It is difficult to detect a male from a female rat in low temperatures without close scrutiny, as the testes may be so elevated on scrotal contraction that their position is in reality abdominal; on hot days, however, the testes protrude considerably in a post-anal position. A similar adjustment follows also for man.

The physical and physiological principles of a local temperature regulator are inherent in the mechanism, and in consideration of all proofs brought forward I have no hesitancy in stating that *the scrotum of mammals is now to be considered a local thermo-regulator for the testes and that the regulatory or functional capacities are indispensable for the production of differentiated germ cells or the maintenance of those already produced.* Not longer than three years ago Cunningham, in his book, *Hormones and Heredity*, stated that "Various causes have been suggested for the formation of the scrotum, but no one has ever been able to suggest a use for it" (page 147). I believe we have not only been able to suggest a use for it but have proved its function and utility.

Objections may be raised against the idea, however, due first to the lack of such a structure in the bird, where the testes are abdominal and the body temperatures even higher than that of the mammal; and second to the lack of it in some mammals (monotremes, elephant, many aquatic forms, bats, etc.). In regard to the first objection may I not state that the bird and mammal are two entirely different animals. Many structural and physico-chemical differences exist between these two forms. Because the testicular tissue is a decidedly heat labile substance in one is no good reason for assuming it in the other; slight physico-chemical differences may produce an entirely different reaction system, and we need not be troubled by such physiological differences, particularly when we appreciate the many structural differences between the two animals. As regards the mammal it need only be mentioned that most biologists now assume that an evolution of animal forms has occurred within the class mammalia as well as among vertebrates as a whole, or invertebrates. In the monotremes, the lower reptile-like mammals in which it is said body temperatures are by no means constant but are subject to wide variations, the testes are

located in the reptilian position, namely, just posterior to the kidneys in the abdomen. As we ascend the scale of mammals a typical scrotum is gradually produced. In some mammals (bat, sloth, etc.) the testes have descended into the pelvic region and have taken up a position against the anterior abdominal wall in a pouch-like depression over which the skin is very thin. It is unquestioned that sufficient temperature adjustment is thus obtained, else we would not have such animals preserved for our edification. In rodents an onward step has been made; the testes protrude into the outpouching of the peritoneum in the inguinal region but the final scrotal condition has not yet been accomplished, as the sacs present a wide open connection capable of permitting passage of the testis into and out of the abdomen. The final closed scrotum is only gained in the higher mammals. It should not trouble us exceedingly that variations have occurred during its evolution—adaptations perhaps—for such have been present even in the evolution of such typical structures as appendages.

We may therefore assume a gradual evolution of a scrotum within the mammal group and may we not, with all justice, consider that perhaps the evolution of the entire mammalian group may have been more or less dependent upon this scrotal evolution? It involves certainly the capacity of the reproductive system to function and therefore the very foundation of the race.

In this general conception, therefore, we have brought together under one fundamental principle an explanation of the behavior of the testis in transplantation, an explanation of the condition of the cryptorchid testis, and I believe we have some insight into the divergent results and misconceptions of vasectomy, and finally the establishment, for the first time, of a proper conception of what has been heretofore considered an apparently useless and even detrimental structure—the scrotum. The established general physiological principles of the testis gives us not only a foothold in the upward climb into an understanding of the biology of this sex gland but it also brings to light some facts that may modify previous surgical procedures.

DISCUSSION

DR. F. C. RODDA (Minneapolis): I would like to ask in regard to the use of heliotherapy, in exposing the patients to the sun's rays, in which there might be a very consider-

able elevation of temperature, would there be any element of danger?

DR. CARL R. MOORE (Chicago): The only way I can answer that is to cite a case of the human testis examined after the application of heat. I believe that melted paraffin has been used by some to reduce inflammations in cases where epididymitis has occurred. One case has been cited where examination showed that the testicle had degenerated; there are always possibilities of a recovery if degeneration is not too severe. Bearing on the same situation, when the testicle is elevated into the abdomen, we know it can almost completely degenerate and still come back to normal. There is nothing to make us believe that the sensitivity of the guinea-pig testis to heat is of the same order as that in the case of the human. It may be possible that the human testis will stand more heat without degeneration; we do not know. But there is not a question of doubt in my mind that extraneous application of heat for too long a time, or for a shorter time and a higher degree of heat, will produce exactly the same type of degeneration in the case of the human testis.

DR. C. N. HENSEL (St. Paul): What about the question of leaving the undescended testicle in the abdominal cavity or in place in the scrotum?

DR. MOORE: Personally, I have had no experience in this matter, but Dr. Bevan I believe has discussed the question (see *Surg. Clin.*, Chicago, 1918, p. 1101-1117). He reports operations on approximately five hundred cases of return of the testes to the scrotum. Of course up to that time the possibilities of recovery were not known. It was not clearly understood that the displacement was the condition which caused the degeneration, and therefore the recovery of this has not been followed excepting in a few cases. Dr. Bevan stated to me personally that he was very certain that reestablishment of the functional activity on return to the scrotum had followed in cases in which the individuals were very young. We do not know how long it may remain in this abnormal position and still be able to return to its functional condition. Dr. Bevan I think under ordinary conditions advises return. He himself has done a great many operations of that character.

THE CHAIRMAN: We are greatly indebted to Dr. Moore for coming this long distance and giving us this very excellent review of his work. It is this sort of thing that we need and we are carrying home something from this meeting with which to meet a good many of the questions that concern many folks, even those who do not reside in Minnesota.

VITAMIN CONTENT OF COD LIVER OIL HIGH

A teaspoonful of cod liver oil contains as much of the fat soluble vitamin as a pound of the best butter, says *Hygeia*, popular health magazine published by the American Medical Association.

That is the reason why cod liver oil is given babies that have a tendency to rickets. As far as calories are concerned, cod liver oil has about the same value as other pure fats, but its vitamin content is far greater than the same quantity of butter, cream or other fatty articles of diet.

THE DIAGNOSIS AND TREATMENT OF NEPHRITIS IN CHILDREN*

F. W. SCHLUTZ, M.D.

Professor of Pediatrics, University of Minnesota

Minneapolis

Nephritis in infancy and childhood differs decidedly and in many ways from that occurring in the adult.

The youth and vigor of its tissues is in the child's favor in this condition as compared with the adult. Its cardiovascular system is generally in good order and has not been hopelessly weakened or damaged by abnormal influences as is so commonly the case in the adult. If the blood pressure does rise, it has little or no effect on the vascular system of the child. Fundamental differences like these, depending largely on the age of the organism, determine to a great extent the types commonly observed and also the prognosis of the condition—the latter always favorable in the child, but quite the other way in the adult.

The cardio-renal type of nephritis, which is without doubt the most common type observed in the adult, is rarely seen in the child—and again the acute hemorrhagic nephritis so commonly seen in childhood is only seldom seen in the adult.

There are essentially four types of nephritis of childhood which the practitioner will regularly and frequently encounter and which he must learn to recognize and differentiate: two acute types, the acute hemorrhagic nephritis and the acute exudative tubular nephritis or nephrosis type; and two chronic types, the mild so-called "pedo-nephritis" of Heubner and the more severe chronic nephritis with contracted kidney and hypertension. More elaborate classifications are often attempted and suggested, but it will be found that the additional types mentioned or included are really only sub-acute or intermediary stages of one of the four types mentioned above.

Acute hemorrhagic nephritis is the most common form of nephritis seen in infancy and childhood. Practically all observers agree that every type of nephritis depends for its development upon some source of infection. They are surely unanimous upon this point in the case of the acute hemorrhagic type. In my experience, infections in

*Presented before the Northern Minnesota Medical Association meeting, Duluth, August 4, 1924.

and about the throat—such as tonsillitis and acute adenitis, especially of streptococcic origin—are the most frequent and common cause. The acute hemorrhagic nephritis following scarlet fever is a familiar picture in the experience of every practitioner. It is always a streptococcic infection. Severe impetiginous skin infections very easily cause acute hemorrhagic nephritis. One should never fail to look for it as a complication of this condition. Gastro-intestinal diseases are a less frequent cause except in the very young artificially fed infant. Pyelo-cystitis, appendicitis, and infections about the teeth are among the rare causes.

In acute hemorrhagic nephritis the glomeruli of the kidney are the chief seat of inflammation. The principal characteristic of the condition is the bloody urine. The urine contains a moderate amount of albumin, quite a number of pus cells, but very few casts. Ordinarily there is very little or no edema present in the case. The kidney takes care of fluid very well. The urinary secretion is generally adequate. Functional tests of the kidney may show a moderate diminution of kidney functional capacity. There is in this type very little tendency to uremia. The heart and blood pressure are normal. The child really does not seem very ill. The tendency is always to recovery in this type. Fatal outcome in the acute stage is rare. Occasionally a case merges into the chronic form.

The second acute type, the nephrosis or exudative tubular nephritis, presents an entirely different picture.

The seat of the dysfunction is not in the glomeruli, but rather in the tubular portion of the kidney. There is swelling and degeneration of the cells lining the renal tubules. These cells are cast off, appearing in the urine as casts. The permeability of the kidney for proteins of the blood is increased. This causes albumin to appear in the urine. The glomeruli are not in any way involved and there is no formation of interstitial fibrous tissue as in contracted kidney. The changes in the kidney are not permanent. These cases can completely recover.

There is a different train of symptoms in this type from that of the acute hemorrhagic. This type of nephritis is also the result of infection. The infection is focal—often quite obscure, but Marriott and Clausen have shown that it can almost invariably be demonstrated in the nasal accessory sinuses. The staphylococcus is most com-

monly present in the lesions found there. The toxic material originating from these lesions is, in the opinion of Marriott and Clausen, the factor responsible for the development of the symptoms in this condition.

The nephritis begins without apparent cause—out of a clear sky while the child seemingly is in good health. There is no temperature and rarely the least evidence of any accompanying disease. The earliest symptom of the disease is edema. Beginning in the legs and then the face or in both places simultaneously, it spreads rapidly to the rest of the body. The edema is very persistent and continually recurs after slight remissions. The amount of edema present is an index of the severity of the case.

In the mild type the urinary output is slightly diminished. Albumin is present. There are a few red and white blood cells and a large number of cellular and granular casts. The heart is normal but there may be slight elevation of blood pressure. Functional tests of the kidney are somewhat diminished. The patient tends to recover from this condition and complete repair of the kidney can take place.

The severe cases present more the picture of adult parenchymatous nephritis. The edema is excessive. There is marked suppression of urine. Often only 2 or 3 ounces of urine are passed during the twenty-four hours. This oliguria often gives way to marked polyuria. There is a great deal of albumin, more blood than in the mild type and large numbers of cellular and granular casts. The blood pressure is generally high. The kidney is unable to excrete salt. This is always true if excessive edema is present. Non-protein nitrogen and urea retention may be high; but generally there is no real retention. The occurrence of uremic symptoms is an ever-present possibility and often does occur; but one must be careful not to mistake an edema of the brain for uremia. The patient may recover entirely without the development of chronic forms of nephritis. This development does, however, not infrequently occur; and the case is much more apt to end fatally at any stage than the acute hemorrhagic form. Marriott and Clausen advance an interesting explanation for the occurrence of the edema. It does not occur because the kidney fails to excrete fluids or salts. They believe that it is the result of change in the permeability of vessels and cells throughout the

body. This permits fluids and salts to pass through vessel walls into cells and serous cavities in an abnormal way. The kidney function may be, and often is, entirely normal and yet fluid is retained in the tissues. Clausen has found constantly present in the blood of the nephrosis type, substances which are capable of changing the surface tension of the blood and the permeability of cells. This substance is excreted in the urine and is produced in the body as a result of infection. Marriott and Clausen believe that this substance is responsible for the changes occurring in the kidney and the development of the edema through its influence on the surface tension of the blood and effect upon the permeability of cells.

Of the two chronic types, the mild type or so-called pedo-nephritis of Heubner is fairly common. Some of the cases occasionally follow the acute hemorrhagic nephritis. Generally they seem to appear from nowhere and without assignable cause. Heubner and most other observers believe, however, that in the chronic types, also, infections play the principal rôle as etiological factors.

The nephritis may last for months or years, with the little patient, except for an anemia, seemingly in good health. There is no edema, hematuria or high blood pressure. All functional tests are practically normal. Casts will be seen only if there are slight acute exacerbations. Most of the cases gradually clear up.

A more severe type, particularly if it follows acute hemorrhagic nephritis, may present the picture of the adult type of chronic diffuse nephritis. There is marked anemia. The skin is pale and waxy. Edema is generally pronounced. The urine is scanty, containing much albumin and many casts and some blood cells. The functional tests show a severely damaged kidney. Uremia is liable to supervene. This type is much more rare than the mild pedo-nephritis. The prognosis is not good.

The second chronic type is the true chronic interstitial nephritis with contracted kidney—a condition similar to the type so common in the adult. It is exceedingly rare in childhood. These cases show polyuria with urine of low specific gravity. There is albumin with few casts. Headache and visual disturbances are common. The blood pressure is high. The heart is enlarged. Albuminuric retinitis is often present. All functional tests are low. The prognosis is always bad. Fortunately,

the condition is exceedingly rare. Symptoms of infantilism are sometimes associated with this type.

There has been much discussion as to the value of the functional tests used in the diagnosis of nephritis. It is safe to say at the outset that they are by no means as valuable or certain in the diagnosis of the nephritis of childhood as they are in that of the adult.

Hill divides kidney function tests into two broad groups: (a) those that measure the power of the kidney to excrete chemical substances not ordinarily contained in the food; (b) those which measure the ability of the kidney to excrete substances ordinarily contained in the food.

The kidney has three important functions. It must excrete nitrogen, salt, and water. The functional tests are based on this fact and are essentially a determination of the rate or volume of such excretion. For practical purposes only four tests need to be considered.

The phenolsulphonephthalein test devised by Rowntree and Geraghty is valuable. It is carried out as follows: From three to six milligrams of dye are injected intramuscularly. All urine passed for two hours is saved. The urine is alkalinized with sodium hydrate and diluted to one thousand cubic centimeters. The intensity of the resulting color is compared with that of a standard solution. The result is expressed in percentage of phthalein excreted in two hours. A normal child should excrete somewhere in the neighborhood of 75 per cent of the injected dye within two hours. An excretion below 60 per cent could be regarded as abnormal function. In the acute nephritis with impaired function the average excretion will run somewhere in the neighborhood of 59 per cent, about 17 per cent under normal; in the chronic nephritis, 63 per cent or about 13 per cent under normal. This test, while probably the best one we have, is nevertheless not always significant in children. Severely damaged kidneys may show almost normal phthalein excretion. A decidedly low percentage of excretion is, of course, always very valuable. It indicates the severity of an acute case and the extent of damage in the chronic case.

The two-hour renal test elaborated by Mosenthal is valuable and can be readily carried out by anyone and anywhere. This test is based on the fact that the kidney expresses its diminished power to functionate by a fixation of its power of concentration. In the damaged kidney the specific grav-

ity of the urine remains fixed for indefinite periods regardless of dietary or other influences. The nitrogen and salt concentration in the urine show hardly any variation. The specific gravity of the urine may be low or high. The technique of the test is very simple. A full diet is given containing a liberal amount of protein, purin extracts and of salt. Hill gives an outline of such a diet.

<i>Breakfast</i>	<i>Dinner</i>
Cereal—2 tablespoonfuls	Chopped Meat—2 tablespoonfuls
Bread—1 slice	
Butter— $\frac{1}{2}$ square	1 Egg
Apple Sauce—2 tablespoonfuls	1 Potato
Milk—6 ounces	Butter— $1\frac{1}{2}$ cubes
Water—4 ounces	Milk—6 ounces
Extra Salt—1 gram	Water—4 ounces
Caffeine Sodium Benzoate—2 grams	Extra Salt—1 gram
	Caffeine Sodium Benzoate—2 grams

The caffeine is added to produce some diuretic effect on the kidney

The fluid allowance is fixed. No fluid is taken between meals. Two hour specimens of urine are collected, starting with six o'clock in the morning and continuing until six o'clock at night. The night urine is collected from 6 p. m. to 6 a. m. The specific gravity of each two-hourly specimen and of the night urine is taken. A fixation of the specific gravity in all the specimens indicates a loss of power on the part of the kidney to vary the concentration of solids in the urine and indicates impaired kidney function. The nitrogen and salt concentration of each specimen can be quantitated, but it is not necessary except possibly for the night urine. In the normal case there should be a difference of at least eight points between the highest and lowest specific gravity of the different samples. It is likely to run even higher. In the badly damaged kidney there is practically no variation at any period. The simplicity of the test and the ease with which it is applied commend it. In cases with marked edema and oliguria, it does not work well.

Determination of the blood urea nitrogen is a valuable test, particularly in the case threatened with uremia. The disadvantage of the test for the practitioner lies in the fact that it requires technical apparatus and knowledge of laboratory technique which may not be at his command.

Persistent urea nitrogen concentrations of 20 milligrams or over per 100 cubic centimeters of

blood should be regarded as abnormal. Still higher values would in a severe nephritis case give warning of impending uremia.

The added salt and urea test has a limited usefulness in children. It is tedious and difficult to carry out. The patient is put on a constant standard diet containing a known amount of nitrogen, salt, and water. The nitrogen and salt of the urine is quantitated daily until the excretion shows constant values. Two or three days are generally required. On the fourth day 5 grams of salt are added to the diet. For two days the urine is analyzed to determine how long it takes the kidney to excrete the added salt. Then 10 grams of urea are added and the rapidity of excretion of this determined in the same way. The test has only moderate value and is altogether too cumbersome.

Hugh Ashby, in the March, 1923, number of the British Medical Journal, describes a simple urea test which may not be without value. It is based on the fact that a damaged kidney is quite incapable of excreting a urine with a high urea concentration. The technique of the test is as follows: The bladder is emptied at 8 a. m. and immediately afterwards 10 grams of urea are taken in about 3 ounces of water flavored with Tincture of Orange. At 9 a. m. the urine is passed and again at 10 a. m. This specimen is kept for the estimation of urea. The urea is estimated by the hypobromite method. If the percentage of urea after the test exceeds two, the kidneys are fairly efficient; if below two, their condition is unsatisfactory. The test is surely simple and can be carried out by anyone.

In using the functional tests, it is better to use them together rather than singly. To some extent they are complementary. They are particularly valuable in determining the prognosis of a given case. Repeated low functional tests at intervals of a few months would warrant a poor prognosis. On the other hand, high phthalein excretion with fairly normal blood urea and good response to the two-hour renal test would indicate that the process is fairly mild and the damage to the kidney not great. Not any of these functional tests can, of course, compare in value with the careful daily clinical observation of a case.

In the treatment of the nephritides of children, two principles must govern. The kidney must be spared as much as possible, and care must be taken to prevent accumulation of waste products in the blood and tissues.

In the diet just two factors must be considered—the protein and the salt content. These substances pass only through the kidney. If the kidney function is inadequate, the partial or complete retention of these substances or their end products causes trouble. All edema cases show marked salt retention. It is quite obvious that in all cases with this symptom at all pronounced, the diet should be salt-free. If the edema is moderate, a slight restriction of the salt, and the use, for example, of unsalted butter may be enough to meet the requirement. If there is no edema, the diet need not be salt-free.

As a general rule, it is not well to restrict fluid intake. It may be useful in cases with pronounced edema. The acute hemorrhagic type would do badly unless large amounts of fluid were given. It is generally safe to give as much water as the kidney can take care of. Most nephritic children can take as much as 48 ounces of fluid without showing weight gain or edema. If the urinary output approaches approximately two-thirds of the water intake, conditions are satisfactory. Even in severe cases of edema, the amount of fluid given should not be below 10 or 12 ounces per day. This amount must be regarded as a minimum requirement. Purging and sweating are good and useful measures, if not carried to excess.

The policy of keeping the protein intake moderate or low in all nephritis cases is probably safe and good, but not necessary in all types. There can be no question about it, of course, in the case showing retention of these products or with persistently low functional tests. A mistake is probably often made in restricting the protein intake too much. Some observers, notably Epstein, even go so far as to advocate a high protein diet for nephritics. The mere appearance of a large amount of albumin in the urine does not mean that one cannot give protein. Many observers have shown that it has no effect on the albuminuria and that it does not appreciably influence the blood concentration of nitrogenous substances. This is particularly true in the nephrosis type. Hill gives the average protein requirement of a nephritic child as somewhere between 1.5 to 2.0 grams per kilogram body weight per day. Neither protein, carbohydrate, nor fat has any influence on the edema. The diet, therefore, except possibly for a limited protein restriction, can be that of any normal child.

Drugs are not very helpful in the treatment of

nephritis in childhood. Some of them, for example the saline diuretics, may even be harmful.

A notable exception is the use of diuretin in the nephrosis type. Clausen has shown that this drug has a definite effect in altering surface tension. Its favorable influence upon edema is explained by this action and has definitely established it as a valuable procedure in the nephrosis type of case.

Diuretic drugs are always contraindicated if there is much hemorrhage. Digitalis is not necessary, as there is seldom any cardiac complication. Complete rest in bed is essential during any acute stage of the nephritis and absolutely necessary in any case showing edema. The moment the disease is recognized, any possible focal infection should be localized and cleared up if possible. The throat, accessory sinuses and teeth should have the most minute attention and thorough care. Recurrences of infection should particularly be guarded against, as the effect upon the kidney promptly manifests itself in the form of relapse or exacerbation of the nephritis.

The prognosis in the nephritides of childhood is uniformly good. Most cases recover within six or twelve weeks. The kidneys apparently can recover their function entirely. It has been quite definitely shown that an attack of nephritis in childhood does not predispose to the development of this condition in later adult life.

The following is an extract from a pamphlet written by a national lecturer for the Universal Chiropractors' Association and sent recently to our state legislators for their edification. Speaking of hay fever, "We say the reason the nose is subnormal is because the 'power within,' that built the nose and adapts it to all the stimuli from without, *cannot* get the adaptative impulses to the mucous membranes of the nose, because a vertebra in the neck is out of alignment and pressing upon the nerve over which these impulses travel, from the 'power within' to the membranes in the nose. We say the cure is self-evident, and consists of adjusting the offending vertebra to normal alignment, thereby removing the pressure from the nerve and permitting the adaptative impulse to reach the membranes of the nose. We entirely ignore the outside stimuli and the patient gets well.

"Absolutely the same explanation is given for all so-called germ diseases. We say for forty years germs have been accused of causing disease of various kinds, but never in a single instance have they been proven guilty. Forty years is long enough to prove anything true that is true, and the mere fact that scientists and the thinking members of other professions do not accept the germ theory of disease is proof in itself that it isn't correct."

JAMES G. GREGERSON.

THE CUTANEOUS LESIONS OF LATE SYPHILIS*

PAUL A. O'LEARY, M.D.

Section on Dermatology and Syphilology,
Mayo Clinic

Rochester, Minnesota

Under the title of "The cutaneous lesions of late syphilis" I have included for discussion those lesions classified as belonging to the stage in which there is a tendency for the *Spirochete pallida* to become localized in the tissues.

I believe also that it is justifiable to include the lesions of the acute phase of the disease, which at times are found in patients who have had syphilis for many years, the so-called recurrent secondaries or relapsing types.

It is true that the transition from the acute to the late phase of the disease is usually very insidious. However, in certain patients this transition may be determined by the objective signs of the disease, particularly the skin manifestations. It might be said that syphilographers tend no longer to use the terms secondary and tertiary syphilis nor to speak of the stage of the infection in terms of years, but rather to speak of the "early" and "late" manifestations of the disease. The reason for this is, of course, readily understood when we consider that the transition from first to second and second to third stages is so indefinite. It is also unjustifiable to speak of the infectious and noninfectious periods, because *Spirochete pallida* have been demonstrated in the borders of late cutaneous lesions, although in very small numbers and after long search. The terms "early" and "late" syphilis are, however, terms of convenience. If this classification is accepted, it is necessary to add an intermediate type when referring to syphilis of the skin: the precocious or malignant, in which are evidences of both early and late stages. In other words, the cutaneous lesions may show simultaneously characteristics of both early and late cutaneous syphilids; also, lesions usually observed in cases of long standing may appear very shortly after the signs of the acute phase of the disease have subsided.

If we will dismiss from our minds for the time being the cutaneous picture of early syphilis, or

the period of dissemination of the *Spirochete pallida* and visualize the late period or the time at which the *Spirochete pallida* tend to localize in the skin or viscera, the classification of the cutaneous manifestations of late syphilis, as shown in Table I, seems justifiable.

SYPHILITIC LESIONS

If the late lesions of syphilis are regarded as granulomas, and if it is realized that the pathologic process is essentially the same in all of these late lesions, the foregoing classification will appear unnecessary. However, the nomenclature of cutaneous syphilis has been developed as the result of visual pictures rather than as the result of pathologic study; hence a classification is necessary. Various names often designate different phases of the same type of lesions.

The study of the immunology of syphilis has advanced considerably during the last few years so that we now endeavor to explain, in part, the various accidents of the disease on this phenomenon of immunity. In the late stage of the infection, or the period of localization of the *Spirochete pallida*, the organisms are scarce in the blood stream, viscera, and cutaneous lesions, due not only to the influence that has been brought to bear directly on the microorganism, but particularly to the protective reaction that has taken place in the tissues. To this reaction of the tissues the term "allergy" has been applied. It is also by this phenomenon that efforts are made to explain the varied pictures often presented by late, as well as early cutaneous syphilis.

Syphilis is notorious in its tendency to recur, or to light up and reappear while not being treated. At the same time it must be borne in mind that modern treatment has done a great deal to upset the mechanism of immunity, as the inadequately treated patient with acute syphilis is prone to have relapses and recurrences. The unfortunate patient who receives just sufficient treatment to break down the allergic reaction and allow the *Spirochete pallida* to remain disseminated and unrestrained, is likely to develop recurrences or relapses, and perhaps malignant or precocious syphilis. The histopathologic picture of the late syphilids is quite identical in all lesions; it is essentially a granuloma having its origin in the perivascular lymph spaces; it is always interstitial and appears first around blood vessels.

*Read before the Minnesota State Medical Association, St. Cloud, October 8-10, 1924.

The recurrent or relapsing lesions.—I may not be entirely justified in including the recurrent or relapsing lesions in a discussion of the late manifestations of the disease, but in view of the fact that theoretically the patient has passed through the stage of dissemination of the organisms when the secondary lesions have involuted, and the allergic phenomenon has been developed only to be shattered by one or several factors, and because of the many therapists who do not interpret the recurrent or relapsing lesions as a result of faulty defensive mechanism, I have included it. The recurrent secondary lesions occur in patients who have not had sufficient treatment during the early infectious period, and in those who have had no treatment, and whose own tissue reaction has been but temporarily developed. There are also certain patients who, in spite of prolonged intensive

ognized mercurial preparation, has been a factor in the production of this complication. The sites of predilection of the recurrent lesions are on the posterior aspect of the scrotum, glans penis, palms, soles, mouth, and the skin (Figs. 1 and 2). The lesions are chiefly of two types: the annular or ring shaped (Fig. 3), and the discrete papular. Depending on their location the papules may undergo maceration and erosion, resulting in the formation of "moist papules". At times there is a tendency for the papules to be grouped or clustered, assuming some of the characteristics of localization observed in the late lesions. The fact that the elementary lesions of this group are essentially papular, although not always necessarily so, and the fact that they tend to localize are evidence of the efforts of the disease to become latent. The *Spirochete pallida* may be easily recognized in

TABLE 1

Manifestations of late syphilis of the skin	{			mucous patches

(Modified from George Henry Fox)

courses of modern treatment, persist in developing recurrent lesions when treatment is stopped, and there are others in whom efforts to obtain abortive cure early in the course of the disease have failed because of the inefficiency of their resistance factors. I have noted that the extensive use of arsphenamin alone, when not followed with a rec-

these eroded lesions, by dark-field examination; hence they are to be classified as infectious. On the glabrous skin the lesions may appear as isolated grouped papules, annular or ring-shaped crudescences, or large gyrate macular figures without induration or necrosis.

Malignant syphilis.—The term "malignant" or

"precocious" syphilis is applied to those lesions which assume the characteristics of late syphilis, but which develop early in the course of the disease. The term early tertiary stage is perhaps more descriptive. The loss of the allergic reaction,

Fig. 1. "Moist papules" or recurrent lesions on the posterior aspect of the scrotum. Highly infectious.

besides an increase in the virulence or numbers of the *Spirochete pallida*, and possibly a dermatropic type of organism probably explain this phenomenon.

The distribution of the lesions of malignant

syphilis may be similar to that of the acute phase of the disease. The salient features are extensive gummatous ulcerations, resembling late tertiary gumma, with the constitutional symptoms of marked asthenia, loss of weight, and general malaise. Occasionally the ulcerations form large, piled-up crusts, to which the name rupia or oyster-shell crusts have been given.

It is fortunate that this form of syphilis is rare because some of these patients seem to be overwhelmed by a spirochetemia, and do not respond to any form of treatment, progressing to marked weakness and death. The majority of such patients, however, respond encouragingly to modern treatment. This form of the disease is often Wassermann negative, which possibly is also an expression of the lack of resistance displayed by the tissues.

Late syphilids.—The true tertiary syphilid (Table 1) is divided into three main groups: the nodular, squamous, and gummatous, each having individual subdivisions. The term "tuberculous gumma", or "tubero-nodular syphilid", and the various other combinations with the prefix tubero, as suggested by George H. Fox, have been omitted because of their tendency to confuse those not trained in the use of dermatologic terms, and because they are not descriptive.

The late syphilid, in general, presents essentially seven main characteristics. It is not practical to discuss these in the order of frequency, or their individual diagnostic value, because the late lesion presents one or two or all of these characteristics

Fig. 2. Recurrent papules on sole of the foot. Note the arciform tendency the lesions assume at the base of the great toe.

in varying degrees. It should be emphasized that every late lesion does not contain all of these characteristics, nor are they always of the same importance in the same type of lesion; likewise, that the diagnostic value of these pathologic processes depends on the location of the lesion; the type of skin, whether brunette or blond; the racial ten-

portant part in the production of gummatous lesions. This has been proved experimentally. It has also been shown that the *Spirochete pallida* exists in the advancing border of the ulcers, but usually in such limited numbers that its demonstration is very difficult. In malignant syphilis the distribution may be that of a secondary syphilid with the tertiary characteristics.

Configuration.—The borders of the late lesions are arciform or polycyclic segments uniting to form arcs or semicircular plaques. This circular configuration occurs not only in the individual nodule or gumma but in the contour of the grouped lesions and plaques. Arciform, serpiginous, polycyclic, and kidney-shape, are some of the descriptive terms applied to the borders (Fig. 4). This characteristic may be explained by the fact that endarteritis and peri-arteritis are important factors in the pathologic process. It must be borne

Fig. 3. The annular recurrent lesions on the buttock showing particularly the arciform configuration.

dencies, and the associated objective findings and collected data. Practically each of these features may be found alone or in combination in other dermatoses, so that the value of each individual so-called characteristic process must be weighed and interpreted in terms of the entire lesion.

Distribution.—The lesions of late syphilis are usually solitary or few in number. In view of the fact that they appear at a time when localization of the *Spirochete pallida* has taken place, the reason for the development of only a few lesions may be readily understood. They may, however, become very extensive and involve large areas, due to their ability to involute voluntarily and to recur, and also because of the simultaneous healing and extension. There are no classical sites for the appearance of the late lesions although there are areas in which their appearance is most common, as for example, the face, scalp, buttocks, palms, soles, shoulder, knees, and forearm. It has been recognized for some time that trauma plays an im-

Fig. 4. The nodular syphilid showing two of the characteristics: the arciform borders and the induration.

in mind, however, that all annular and round lesions are not syphilitic; they are often noted in other diseases such as the trichophytoses, erythema multiforme, granuloma annulare, and certain types

of epithelioma. The configuration is more distinct at a distance of 6 or 10 feet than close to the lesion.

Induration.—Induration or deep infiltration is a characteristic of practically all the late lesions of

Fig. 5. The superficial atrophic scar of the late syphilid; friable, soft, wrinkled, retaining the configuration of the original lesion.

syphilis. The degree of induration is dependent on the depth of the infiltration, and with experience may readily be differentiated from the induration of other granulomas. Particularly is the element of induration of diagnostic importance in the papular and nodular types of the disease. It has a definite diagnostic importance only when combined with other findings.

Destructiveness.—The late lesions of syphilis are, as a rule, destructive. Although they may not always undergo necrosis, replacement by fibrosis, with the other characteristic changes, is always of diagnostic value. The subcutaneous gummas may ulcerate or involute without destroying the skin. The amount of destruction varies with the depth of the infiltration. It is true also that the amount of scarring is proportionate to the amount of destruction of the deep tissues, although there may be scarring without ulceration of the skin.

Atrophy.—The pathologic process in the more superficial lesions is a loss of the elastica, resulting in atrophy, which is characteristic of the late lesions, and, even when occurring alone, is of considerable diagnostic value (Fig. 5). The scar is

usually of the thin, wrinkled, non-contractile, pliable, tissue-paper type, which retains the configuration of the lesion. In the massive granuloma the scarring may be extensive and deforming, depending on the depth of the involvement and the amount of the invasion of the underlying structures, such as bone and muscle. Superficial scars also result from epithelioma, various forms of cutaneous tuberculosis and superficial burns.

Residual pigmentation.—The peripheral residual pigmentation may persist for a considerable time after the granuloma has completely involuted. The pigmentation also retains the original configuration and the outline of the lesion. Many other dermatoses likewise resolve, leaving a residual pigmentation, particularly lesions in which stasis is a factor, and therefore residual pigmentation in itself is not pathognomonic of tertiary syphilis.

Fig. 6. Classical late syphilid showing the characteristics of the arciform configuration of the advancing border, peripheral extension, scarring, atrophy, and residual pigmentation. The induration does not show in the photograph.

Peripheral extension.—The tendency for the one-sided healing in the gummatous lesions with peripheral or centrifugal extension is common (Fig. 6).

The resulting scar which retains the configuration, pigmentation, and atrophy frequently breaks down and develops recurring granulomas some time after complete healing. The advancing border due to the coalescence of the nodules or ulcerated gumma, or of both, retains the diagnostic arciform configuration. The individual lesion, as well as the group of the lesions, retains this kidney-shaped, arciform, circinate, or polycyclic border.

Individual types of late lesions.—The predominate lesion of late syphilis is the gumma, and, depending on its visual characteristics, it may be roughly classified as nodular, squamous, and ulcerated. Depending on its secondary changes it may be serpiginous, agminate, circinate, rupial, verrucous, or cicatricial, either circumscribed or diffuse.

The nodular type, which is particularly common around the face, buttocks, and thighs, presents the characteristics of one or a few clustered, indurated nodules, with an arciform border, which may ulcerate, or involute without ulceration, resulting in the classical atrophic pigmented patch. This type of lesion must be differentiated from lupus vulgaris, fibroma, lipoma, chafed areas, sebaceous cysts, sarcoids, and rhinoscleromas. The salient features of this type of lesion are the induration and the border previously described, and the color, usually a dark cherry red, shading at the periphery to a brown which, although not pathognomonic, is of diagnostic value.

The serpiginous syphilid is a superficial nodular type of lesion that may or may not ulcerate, but extends peripherally, leaving a thin atrophic scar. The individual nodules desquamate, producing a scale, and at times a crust, if ulceration has occurred. The serpiginous syphilid must be differentiated from lupus vulgaris, psoriasis and epithelioma.

The squamous syphilid, which is most common on the soles and palms (Fig. 7), is at times difficult to distinguish from the common eczema, psoriasis, and trichophytosis of the palm. It is characterized particularly by atrophy, an arciform or circinate border, and tight adherent scales. It may be bilateral although it is usually unilateral. Vesicles, pustules, and pruritus are not found in the squamous syphilid, while atrophy, its most prominent characteristic, is not found in the differential possibilities. The presence of psoriasis elsewhere on the body helps confirm such a diag-

nosis. Also the recognition of mycelium from scrapings is a valuable differential point in the diagnosis of trichophytosis.

The gummatous lesions are not always characterized by ulceration, as this is merely a late phase of the gummatous process. Gumma may be either solitary or multiple; the former being the more difficult to diagnose because fewer diagnostic signs are present in the solitary lesions. As a rule there is very little pain with gummatous lesions, and the adjacent nodes are not affected. The non-ulcerated gumma may involute spontaneously or break down, fluctuate and ulcerate. The resultant necrosis has the characteristic configuration, with crusts growing freely on a dirty ulcer base, and induration, with a tendency to extension and healing at the same time. The gummatous lesions must be differentiated from two other main groups:

Fig. 7. Squamous syphilid of the hands. Note the outline of advancing border, also the atrophy along the index finger.

lesions occurring before ulceration, and those occurring after ulceration. Before ulceration, the differential possibilities are erythema nodosum, furuncles, and lupus vulgaris. After ulceration the possibilities are more numerous and include varicose ulcers, sporotrichosis, traumatic ulcerations, ecthyma and scrofuloderma.

Rupial lesions are ulcerated gummas on which the crusts, made up of inspissated pus, have piled up layer on layer until they have taken on the appearance of oyster shells. The crusts persist so long as active ulceration lasts.

Scars.—Scars of late syphilids are diagnosed by the residual atrophy, pigmentation, configuration and the amount of destruction caused. Certain scars, such as those of erythema induratum, burns,

and certain basal cell epitheliomas, are almost indistinguishable, so that it frequently is necessary to look for other evidences of syphilis before reaching a final conclusion.

Leukoderma coli, or residual depigmentation and atrophy around the back and sides of the neck, is a valuable diagnostic finding.

Mucous membranes.—There are essentially four manifestations of late syphilis of the mucous membranes which are worthy of emphasis, the recurrent mucous patches and moist papules, atrophic glossitis, leukoplakia, and nodular and ulcerated gummas. Gummatous involvement of the bony structures of the mouth may result in perforation and necrosis of the mucous membranes.

The recurrent mucous patches may or may not be associated with the cutaneous recurrences. The characteristics are like those of the secondary mucous patches of the mucous membranes. A recurrent papule, because of its environment, becomes eroded and macerated, resulting in a small gray plaque, the borders of which are sharply circumscribed. The surface of these lesions swarm with *Spirochete pallida*.

The late lesions of the mucous membrane of the mouth are like the typical nodular and gummatous lesions of the skin. The tongue, fauces, and nasopharynx are the most common sites. A third type may be included in this group: sclerotic or atrophic lesions. These occur most often on the tip of the tongue in the form of atrophic glossitis, but at times the entire tongue may be atrophic. Interstitial glossitis of the entire tongue is also met with.

Leukoplakia of the mucous membrane is the most common of the late manifestations of syphilis of the mucous membranes (Fig. 8). There is also a type of leukoplakia which is the result of constant irritation and is not associated with syphilis. The syphilitic type is usually associated with atrophic glossitis, and differs clinically in that it is not the smooth, pearly white, glistening plaque of the traumatic type, but tends rather to be striated, of a bluish tint, and likely to be located where there are no sources of irritation, such as snags of teeth, tobacco cuds, and pipe stems. The removal of leukoplakial patches with cautery or radium is warranted not only as a prophylactic against malignant degeneration, which is quite common, but also to prevent the development of more leukoplakia. At the same time the removal of such irri-

tating influences as pipe stems and snags of teeth, is essential. Although nine different types of affections of the nail have been attributed to syphilis, there are really only two that are seen often enough to warrant mention here: the syphilitic onychia, and the spade nail as described by Varney.

Syphilitic onychia and pronychia may affect a few or all of the nails. The onset is insidious, with thickening, increasing brittleness, furrows, and depressions in the body of the nail. The matrix is, as a rule, affected so that the nails are shed from time to time, and are replaced at first by ill-formed nails. Suppuration and ulceration of the surrounding tissue may occur. The absence of pain is characteristic in syphilitic lesions of the nail. Of course, it is necessary to differentiate these lesions from trichophytic diseases, trophic disturbances, and psoriasis.

Fig. 8. Syphilitic leukoplakia with the associated atrophic glossitis.

The alopecia of the scalp of late syphilis is usually the result of a gummatous process that has subsided, leaving a scar that results in the destruction of the hair roots and bulk. Such signs as thinning of the hair are of minor importance.

The average Wassermann reaction in patients with late syphilis is 87 per cent positive; in other words, in the type of disease in which the Wassermann or the Kolmer test is the least necessary the percentage may be the highest. The frequent finding of the so-called Wassermann-fast group in

cases of late cutaneous syphilis, has been emphasized by Stokes. He reported that 17 per cent of cases of late syphilis eventually became Wassermann-fast cases. Half of these were shown to have evidences of cardiovascular involvement, and 6 per cent invasion of the nervous system.

In a review of the late cutaneous lesions, as observed at the Mayo Clinic, the following types and their frequency are noted: nodular 49 per cent; squamous 10 per cent; gummatous 26 per cent; and miscellaneous 15 per cent. This grouping is based on all the patients with cutaneous syphilis that have been examined at the Clinic. Of all the patients admitted with syphilis, 24 per cent were found to have evidence of cutaneous late syphilis. Weiss and Conrad report that 25 per cent of the syphilitic patients observed at the University of Washington in St. Louis, show evidence of late syphilis.

SUMMARY

The various types of recurrent and late cutaneous syphilis are itemized, and their important characteristics emphasized. These are the types of late syphilis in which the need for confirmatory serologic tests is least because the clinical findings are usually sufficient to warrant a diagnosis. The signs are valuable as aids to the diagnoses of syphilis of the viscera, and so forth, when the Wassermann test has failed to confirm a suspicion, the recognition of the cutaneous evidence of late syphilis clearing up an otherwise embarrassing situation.

CLINICAL OCULAR TUBERCULOSIS*

JOHN F. FULTON, M.D.

St. Paul

I have chosen for my subject Clinical Ocular Tuberculosis, a subject in which I have become intensely interested from a practical standpoint in the last few years. For a long time oculists seemed to be of the opinion that tuberculous infection attacked only the choroid and posterior parts of the eyeball. We now know, however, that all ocular structures may be attacked either by the tubercle bacilli or the toxin produced by the accumulation of these organisms in parts of the body remote from the eye itself.

The clinical pictures of tuberculous diseases of the eye, as they show themselves anteriorly, are now quite familiar to the experienced oculist and it is not my purpose to describe them in detail here. All degrees of ocular pathology due to tuberculous infection are met with from the mildest cases of phlyctenular keratitis and conjunctivitis to keratitis profunda and from slight and quickly disappearing congestion and small hemorrhage of the fundus to massive exudates and rapid destruction of the ocular structures.

The literature of this disease has increased enormously in the past ten years and the success in treating this unfortunate infection I am happy to say has kept pace most satisfactorily with our knowledge of the disease itself. The vast majority of cases of the various forms of ocular tuberculosis is secondary to an infection elsewhere, but that it is sometimes primary in attacking the conjunctiva can no longer be doubted. I am not unmindful, however, of the fact that bodily epithelial coverings are resistant to bacterial infection, so primary tuberculosis of the eye can only take place as a result of trauma.

Our knowledge of the clinical phenomena of ocular tuberculosis has been vastly augmented by experiments recently made by some of the most prominent ophthalmologists, and chief among them Dr. William C. Finnoff, who has demonstrated that every type of ocular tuberculosis met with in the human eye can be reproduced in animals, and that the animals thus infected presented almost the same identical picture as that which we

*Presented before the Northern Minnesota Medical Association, Duluth, August, 1924.

see in the human eye. The most interesting part of the experiment is the fact that the introduction of an emulsion of the virulent tubercle bacilli into the healthy conjunctiva produced no result, but when the conjunctiva was incised or bruised, typical tuberculous conjunctivitis resulted. Thus being able to produce tuberculous lesions in the eyes of the lower animals at will, has added immensely to the accuracy of our study of ocular tuberculosis.

Tuberculous conjunctivitis is not very common, but is met with sufficiently often in our practice to require a more careful study than it has yet received. It is met with in various forms:

1. Ulcers with ragged edges in which may be found the tubercle bacilli.
2. Cockscomb-like granulations closely resembling trachoma.
3. Tumor-like peduncular structures.

Tuberculous conjunctivitis is the most typical illustration of primary tuberculous disease of the eye, as particles of dust with sharp edges or foreign bodies of any kind having on their surface the tubercle bacilli may bring about this form of inflammation and by extension to surrounding structures may produce the same disease in the lacrimal apparatus and other adjacent structures.

Igersheimer contends that tuberculous conjunctivitis is always primary.

Perhaps the most common form of inflammatory disease of the eye to be mistaken for other inflammatory troubles is tuberculous iritis, which is secondary to a primary focus in some other part of the body, usually the lungs. The symptoms of tuberculous iritis are very much the same as other forms of iritis with the addition of the formation of the nodules. They are usually to be found close to the pupil or the ciliary margins. In the early stages they are very small, requiring the aid of the loop to be seen. Only too often "K.P.s" can be found on the posterior parts of the cornea, indicating ciliary involvement; occasionally, they become massed together, presenting the appearance of a yellowish-white tumor. At this stage this form of iritis may be mistaken for gummatous iritis; a negative Wassermann or the failure of the ocular congestion to respond to tuberculin guides us to a correct diagnosis. Associated with this is usually a well-marked circum-corneal ring of congestion. If the case is tuberculous, the congestion is intensified by a small hypodermic injection of tuberculin.

In this way tuberculous iritis is differentiated from the same disease due to other causes.

A most careful study of this form of tuberculous infection was made by Dr. E. B. L. Brown, of Chicago, which he read in the section of Ophthalmology of the American Medical Association at its 56th annual meeting. A splendid review of the literature on the subject up to that date was published with this paper.

Tuberculous keratitis has also become a most interesting study in recent years. This lesion shows itself in the form of nodules, large and small, in the corneal structure, usually complicated by intense vascularity and photophobia. This condition is usually the result of the extension of the disease from the uveal tract, although a number of cases have been reported in which the starting point was trauma. It is in this form of tuberculous disease that we often have the most wonderful results by the careful and prolonged use of small doses of tuberculin. This refers especially to that variety of non-healing abscess and ulcer of the cornea, formerly called scrofulous.

In addition to the already described types of ocular tuberculosis, we meet with disease of the fundus due to systemic tuberculosis. This usually shows itself in a periphlebitis and vasculitis resulting in repeated hemorrhage into the vitreum and retina and also in certain forms of exudative chorio-retinitis. This may occur independently or associated with the different forms of this disease described in this paper.

Von Hippel recently reported a case in which after the disappearance of the deep corneal infiltration and iritis with typical nodules, characteristic pictures of retinal perivascular tuberculosis became visible. Under tuberculin, all the foci healed entirely.

Notwithstanding the enormous number of most favorable reports we find in the pages of ophthalmological literature in regard to the successful treatment of tuberculous eye diseases by tuberculin, we still occasionally meet a "doubting Thomas" who fails to recognize its value, although Fuchs, with whose genius and unerring judgment we are all familiar, declares that he is now able to save eyes that he formerly enucleated, with resulting good vision, by the prolonged use of small doses of tuberculin. Men like Treacher Collins speak in the highest terms of its usefulness. DeSchweinitz reports in his text book the wonderful results in

treating this same class of disease by this very reliable therapeutic agent.

After having observed with careful attention the beneficial effect of tuberculin in a vast number of cases myself, I agree with what Von Hippel declared in one of his early reports that we possess in tuberculin a means which if rightly used will permanently heal sufferers from tuberculosis of the eye.

I also agree with Mr. C. J. Campbell Faill of Bristol in regard to tuberculin, that its use requires knowledge and care and in no department more than in the treatment of tuberculous disease of the eye, but if administered judiciously and skillfully, it can, in a very large number of cases, produce complete and permanent cure. However, in eye lesions, associated with active lung disease, the best results are obtained by sanatorium treatment rather than by tuberculin.

In a recent paper, Goitz sums up by saying that tuberculin is a most valuable agent. The tuberculous lesions improve under its use and cure takes place in the majority of cases. Its principal field of usefulness is when simple therapy fails. It should be used as early in the disease as possible. Dr. E. B. Miller, of Philadelphia, has reported some cases of delayed union following operative procedures which healed promptly under tuberculin treatment after all other remedies had failed.

Drs. Jackson, Magruder and others have called our attention to the distressing asthenopia which is met with in tuberculosis subjects which are greatly relieved by carefully correcting the refractive and muscular deficiency, thus adding much to the comfort of the patients during their convalescence.

A word in regard to the phlyctenular group of eye diseases: the evidence that they are the result of tuberculous infection is overwhelming.

Dr. Wilder, when he was Chairman of the Committee of the Ophthalmological Section of the American Medical Association for the study of the relation of tuberculosis to diseases of the eye, reported that in 51 cases of phlyctenular diseases of cornea and conjunctiva, 47 showed distinct evidence of tuberculosis, either in quiescent or active form. Colmans, in his recent paper, called our attention to x-ray demonstration, that the majority of patients belonging to this group have enlarged broncho-tracheal glands. Weekers and Colmans have pointed out in recent writings that evidence of this is accumulating more and more as we con-

tinue to investigate. In 50 cases recently examined, enlargement of the broncho-tracheal glands was demonstrated.

Through the instrumentality, foresight and energy of Dr. H. Longstreet Taylor, of St. Paul, we have established in our city a Preventorium for the care and treatment of tuberculous children. For a number of years the St. Paul Free Dispensary has been sending its ocular tuberculosis cases to this well-managed institution. Many of these children developed phlyctenular keratitis and conjunctivitis. I have had the opportunity to make a careful study of treating them with and without tuberculin. In those instances where, for some resulting in repeated hemorrhage into the vitreous reason, tuberculin treatment was neglected, the children made little or no improvement as to their eye condition, but with the tuberculin treatment all these symptoms disappeared with marvelous swiftness to the perfect satisfaction of parents, nurses and physicians. Not only did this treatment seem to relieve the eye conditions, but it aided quickly and most satisfactorily in the improvement of their general condition.

Associated with the St. Paul Free Dispensary is a most efficient tuberculosis department conducted by Dr. E. B. Daugherty. All of our tuberculous eye cases are referred to that department and the treatment conducted and applied by Dr. Daugherty. We have the same arrangement now with our new dispensary service directed by the Wilder Charities.

The kind of tuberculin used is not a matter of importance, but it is important for the physician to comprehend the underlying principles of tuberculin therapy together with its limitations. The type of cases and the dosage suitable to each individual case is far more important than the kind of tuberculin used. Tuberculin, therefore, is one of the most useful therapeutic agents that we have at our command when suitably applied and one of the worst and most dangerous in unsuitable cases and unsuitable dosage.

DISCUSSION

W. E. PATTERSON (Minneapolis): Dr. Fulton has selected a very interesting and vitally important subject for his paper. Tuberculosis of the eye is a disease that until recent years has been little understood.

In retrospect, we who are engaged in treatment of eye disease can see where we have failed to recognize this very common form of ocular disease because of our lack of

knowledge of tuberculosis in its incipency, and the many varied forms occurring in its development.

At the present there is a great difference of opinion as regards the presence of primary ocular tuberculosis.

The difficulty which Dr. William H. Finnoff, of Denver, encountered in his experiments on rabbits' eyes in establishing an infection of the external structures of the eye would lead to the supposition that exogenous infection would be very much the exception if it ever does occur, and that intraocular tuberculosis must be of metastatic origin, as it was necessary in every instance to introduce the virulent organisms directly into the tissues to get a lesion. When the organisms were injected into the blood stream, all forms of intraocular lesions that are common to man were seen to develop.

Tuberculosis of the eye occurring in childhood has been insufficiently studied, especially from a histological standpoint. There may be no other evidence of infection and Pirquet's reaction may be negative.

Tuberculosis should always be considered where acute or chronic inflammations, particularly of a recurring type, do not yield readily to treatment and where no other form of infection can be determined, bearing in mind that it is a common cause of keratitis, cyclitis, choroiditis and scleritis.

As yet I have found no explanation for the absence of the Pirquet reaction in many cases of ocular tuberculosis in children, or for the rarity of ocular tuberculosis in the presence of extensive lesions in other parts of the body.

The development of tuberculin therapy, as is in use today, has made it almost specific in the treatment of early tuberculosis and is a real scientific achievement. Hence the need of early diagnosis.

We should always bear in mind that the best results are obtained by starting with the infinitesimal dose of tuberculin and gradually increasing as the patient shows evidence of immunity.

DR. TUOHY (Duluth): As I have listened to this very interesting paper by Dr. Fulton, I am attracted particularly by what he says relative to the influence of tuberculin upon

the lesions which can be so easily watched during the course of treatment and essential changes noted. Tuberculin, in the treatment of general tuberculosis, and notably tuberculosis of the lungs, has been more or less abandoned. Nevertheless, there has remained this very logical use for tuberculin in conditions of the eyes, and we know that it has a decided field of usefulness in localized tuberculous adenitis. Possibly if we knew more about how to use it and under what exact conditions, it still might be found, as in the hands of some men who still use it, to have a much wider field of accepted usefulness.

We are much indebted to Dr. Fulton for this splendid review.

DR. CALLAHAN (Pokegama): It is very interesting for those of us who are engaged mainly in the treatment of pulmonary tuberculosis to hear something of the diagnosis and treatment of the more special tuberculous conditions.

In a very limited experience with tuberculous eye conditions, I agree quite heartily with Doctor Fulton on the value of tuberculin in the treatment of ocular tuberculosis in the absence of a progressive tuberculous lesion in other parts of the body. About three years ago, Corper and his co-workers of Denver published an article on the eye as a portal of entry for tubercle bacilli in pulmonary tuberculosis. In Corper's opinion, many viable tubercle bacilli get into the eye from dust and the spray from the cough of positive cases, which are carried through the tear ducts into the posterior pharynx and from the pharynx into the trachea and lungs in a very short time. It just occurred to me that in cases of previous injury or disease of the conjunctiva some of these bacilli may occasionally cause a primary ocular tuberculosis.

DR. A. T. LAIRD: I was very much interested in Dr. Fulton's paper especially in his reference to the use of tuberculin. In no form of tuberculosis has the value of the tuberculin treatment been more thoroughly established than in lesions affecting the eye. Several of our patients who have had keratitis and phlyctenular conjunctivitis have improved under tuberculin treatment given in connection with usual sanatorium care.

PHYSICIANS ATTACK MACFADDEN JOURNAL

An attack on *Physical Culture* magazine, a Bernarr Macfadden publication, is featured in the November *Hygeia*, popular health magazine published by the American Medical Association.

The magazine announces that this is the first of a series of articles entitled "Exploiting the Health Interest" which will discuss the manner in which the desire for health and the hope of relief from suffering and disease are exploited by promoters of peculiar cults and fads.

"Future articles," says the magazine, "will deal not only with other Macfadden periodicals but also with all the prophets of nondescript cults that thrive on the delusions they create in the minds of the sick."

After characterizing *Physical Culture* as a magazine edited for morons, every issue of which reeks with sex appeal, *Hygeia* takes up the type of advertising that makes *Physical Culture* commercially profitable. It publishes reproductions of advertisements, formerly carried by *Physical Culture*, of concerns that have been declared frauds by the federal government and debarred from the use of the mails.

"The amount of harm that *Physical Culture* does is incalculable," says *Hygeia*. "Not only does its advertising pages inevitably tend to destroy public confidence in the printed word, but its editorial pages pervert public intelligence on matters pertaining to scientific medicine and promulgate doctrines that have pernicious and far-reaching effects on the public health."

PERIODIC PHYSICAL EXAMINATIONS*

HENRY W. COOK, M.D.Vice President and Medical Director
Northwestern National Life Ins. Co.*Minneapolis*

Osler said that "Sanitary science, hygiene, or preventive medicine may claim to be one of the brightest spots in the history of the nineteenth century;" and certainly in the twentieth century so far, the distinguishing emphasis of scientific medicine has been on prevention rather than on cure.

While this fact is more or less generally recognized, we may not keep in mind the profound changes that it has been responsible for in both medical theory and practice. The "healing art," which was for centuries descriptive of the scope of medicine, would today be grossly inadequate. The limits of "healing," or the restoration of diseased tissue, especially of the chronic types, are so restricted as to make medical practice relatively discouraging, were not this vast and largely unexplored field of prevention widening before us.

While each of the steps in the preventive field have been notable in themselves, they have only gradually brought to the medical profession a new conception of its relationship and obligation to the general public. The traditional attitude of medicine has been mystical, secretive, exclusive. Perhaps as a healing art this had some justification. The prescription written in Latin probably carried added potency, but in the preventive field the educated, enlightened co-operation of the lay public is absolutely essential to any real progress.

As a conception of the possibilities of preventive medicine has gained a hold on the imagination of the profession, and the necessity for the education and understanding of the public becomes recognized, our members have gradually—all too gradually—reversed the traditional attitude, and are now seeking to educate the layman into the principles underlying medical science, and into its practice as it relates to the preservation of health and prolongation of life.

Two striking illustrations, from many, will suffice to show the necessary trend from medical practice as a healing art to preventive medicine as a universal social benefaction.

First came the discovery and use of quinine as a cure for malaria, a method of healing for medical practice; then the discovery of the mosquito as the carrier of the malarial parasite, and the method of prevention for the state and the public at large.

Also, the treatment of diphtheria by intubation, a real contribution; then by antitoxin, a far greater contribution,—both a method of healing for medical practice. But now we have toxin-antitoxin, the greatest of all, but requiring the intelligent and informed co-operation of the public to be made effective.

Preventive medicine, both from the professional and lay viewpoint, has no more important, though relatively neglected, opportunity than the periodic physical examination. Here the layman is absolutely dependent on the medical profession for service, instruction, and advice. He cannot, as in other fields of preventive medicine, take this scientific contribution as he did the discovery of the transmission of malaria, and apply it by sanitary regulations or engineering methods.

In the prevention or treatment of practically all forms of disease—acute, chronic, infectious, or toxic—the periodic physical examination is of the greatest value, both in maintaining a standard of personal hygiene and health which may prevent the onset or modify the progress of disease, and in showing the earliest stage of disease when it may be susceptible to cure or arrest.

Today, the wisdom of the periodic physical examination is so generally conceded that it is a matter of astonishment that it was little heard of until the past decade, and that it is comparatively so little practiced by the profession or the layman.

It will not be the purpose of this paper to present the blanks of the periodic examination, nor to cover in detail the diseases which it may reveal, nor the treatment which may be based upon its data. Approved forms have been prepared by a committee of the American Medical Association, and are obtainable from that organization; the symptoms and signs developed, and their interpretation, are merely clinical medicine.

It may be of interest, however, to inquire into the cause of the comparative failure of the periodic physical examination to gain its proper recognition in practice, and also whether experience so far obtained justifies the claims made for it.

*Presented at the annual meeting of the Minnesota State Medical Association, St. Cloud, Minn., October 19, 1924.

There are two essential factors in the successful practice of the periodic physical examination:

1. An educated public,
2. A competent profession,

each being very dependent upon the other as a necessary complement.

Education is a slow and laborious process in any field of knowledge. This would be true if all adults reached even a moderate degree of mentality. But when mentality is of such wide variation, and when so large a proportion of the population is of very low natural intelligence, and equipped with but meager education well diluted with superstition, ignorance, and misinformation, it is easier to understand the very gradual spread of the appreciation and utilization of some of the most important scientific contributions.

Sickness has for ages been thought of as the punishment or manifestation of displeasure of gods or a god, depending on the particular theological dogma; and the most potent preventive measures have been prayer or votive offerings, supplemented in the post facto emergency of active illness by the remedial devices of the healing art.

Belief in sickness as sin and health as virtue, uninfluenced by mere material conditions, is only a modern variation of this superstition, which is even today reflected to a greater or less extent in the prayers, doctrines, and practices of nearly all varieties of religious faith.

As appreciation of the value of the periodic physical examination is incompatible with such a belief, it is not so surprising that progress is slow. The layman must be taught to realize that health is determined by a normal functioning of the spiritual, mental, and physical elements in the human trinity; that a careful history and examination will in many cases reveal that an abnormal condition exists in one or all of these factors, and that knowledge of the true condition existing at certain periodic intervals gives an intelligent basis for continuing a condition of health or correcting any abnormal variation which may be present.

However, in spite of reactionaries and fundamentalists in secular directions as well as in religion, education is spreading rapidly, and ignorance and superstition are giving way before it. More and more, national and local legislative action is based on the Gladstone doctrine that "In the health of the people lies the strength of the nation." This has been for long recognized in the

emergency of war, but now is recognized in the progress of peaceful development.

It was interesting and encouraging recently to have Secretary of War Weeks ask for national health as a feature of Defense Day, calling upon the medical men in each community to "issue friendly advice to their fellow citizens" and to provide for examination to assess the "vitality of our citizenship."

Industrial competition is a new and potent factor in education for better health standards. Most industries of the higher grade now require health as a condition of employment, and inaugurate employment with a physical examination, required or offered at subsequent intervals not longer than one year throughout the period of service.

Life insurance companies, with their fully equipped medical departments, have had wonderful opportunities, only partly embraced, to spread through policyholders and agents sound health propaganda. Many of these companies are offering periodic physical examination free of charge to policyholders and employees,—and about 5 to 7 per cent take advantage of this offer.

Several cities—Pittsburgh, Boston, New York—have offered periodic health examinations at municipal clinics, and these have been well patronized.

Numerous commercial enterprises, more or less legitimate, have sprung up in response to the popular demand for these health examinations. One of them, the Life Extension Institute, cannot be too highly praised for the splendid educational and practical work which it has done through its bulletins, advertisements, and health service. Many other similar institutions, however, are merely quack replicas of the Institute, and are doing the cause of legitimate preventive medicine much harm.

There is, however, some evidence that public education in the periodic physical examination has advanced beyond the stage where adequate appreciation by the medical profession always meets the need. It is a very common experience in insurance medicine and in periodic physical examination work to come across instances where interest of the layman in his health or in health examination has been ridiculed or discouraged by the physician, or met with indifference. Some physicians take the position that periodic examinations tend to make the individual nervous or a hypochondriac. A re-

quest for a careful examination is met by a joking reassurance.

The time is passing, however, when jovial optimism can acceptably replace careful, intelligent, and scientific clinical methods. Optimism may be the wisest of therapeutic agents, but, as with any therapy, it should follow and not anticipate or replace diagnosis. Any such reversal of sequence is extremely dangerous.

Comparatively few practitioners today, except pediatricians, oculists, and dentists, are urging periodic health examination on their patients. This failure is due to several causes. In the first place, in city practice the family physician is becoming less common, and obviously a patient cannot go to ten or twelve specialists each year for as many special examinations.

Then again, the practitioner often hesitates to urge well people to come to him for periodic examination for fear that he may be suspected of urging unnecessary work and expense for his own profit.

Possibly some physicians are too careless and slipshod in their history records and examination methods to make worth-while use of the periodic physical examination opportunity and data.

Undoubtedly, also, some physicians are skeptical about the real value of the periodic examination. It is quite true that it has not fully met all the enthusiastic claims that have been made for it. It has suffered, as have other good movements, at the hands of its friends. Periodic examinations will not make everyone live to old age. Their possibilities are strictly limited. Medicine is far from an exact science. Even with the most complete and prolonged clinical and laboratory examination, disease may be overlooked and data misinterpreted. An ordinary periodic examination must be relatively simple and superficial.

Less emphasis should be placed upon the value of the periodic examination in revealing disease, and more stress should be put upon its great value in health education. At the periodic examination the opportunity can be utilized, by the wise practitioner, to teach men, women, and children to live wholesomely, not necessarily or merely to have some insidious disease detected.

And above all must the profession take the opportunities offered by the periodic examination for profitable treatment or operation, with the greatest conservatism and singleness of purpose. The man who recommends that he or his consulting col-

league remove every enlarged tonsil found on examination, treat every symptom or correct every physical deviation from an arbitrary standard, is practicing meddlesome medicine or surgery, and is discrediting his profession.

But while frankly facing the possibilities of abuse, let us not fail to appreciate the great value of the periodic physical examination, nor the high standards of service and practice by the large majority of the profession.

The periodic examination is educational to the patient and the physician,—each knows the other better, to their mutual advantage, both during continued health and also when any symptoms or signs develop. Rather than making a patient nervous, a well-conducted physical examination is the best possible remedy to calm and relieve nervous fears. If an examination worries or distresses a patient instead of cheering and comforting him, the physician who has such an experience should closely examine his own methods and mental attitude.

Each step in the examination gives opportunity for advice and counsel in the prevention of disease and maintenance of health of priceless value—if the examiner is qualified to give it. Posture, weight, mental attitude, work, exercise, diet, water, sleep, recreation,—and all the other factors known to modern science as of so much more importance in maintaining health than medication or operation,—are discussed to the infinite benefit of the layman.

And of importance, too, is the finding of early and curable disease,—the trace of sugar or albumin, the rising blood pressure, the neglected eye strain, the toxemia, the early or precancerous ulcer or tumor, the beginning thyroid enlargement, anemia, and other signs and symptoms which may be invaluable indications of needed treatment.

Ordinarily it would be extremely difficult to accurately evaluate the good accomplished in promoting health and prolonging life by such a variable factor as the periodic examination, but fortunately there are several sources of information which throw a definite light on the subject.

In factories and offices where the periodic examination has been adopted as a routine practice, a very marked reduction in absenteeism for sickness has been observed. There are usually other favorable factors introduced at the same time, such as more adequate treatment, health educational

propaganda, etc., but unquestionably the periodic "health audit" is a most important factor.

When we realize that \$3,000,000,000 is the annual tax levied by illness last year in this country, we can gain some conception of the need for every possible preventive measure.

The most striking proof, however, of the definite value and benefit from the periodic examination, is the experience of the Metropolitan Life Insurance Company. This company was the first to offer its policyholders periodic physical examination, which it did through the Life Extension Institute, immediately on that institution's organization in 1914. From 1914 to 1922, 63,000 periodic physical examinations were made, at a cost to the company of \$225,000. In order to obtain as long an experience as possible, the policyholders who took the examination during 1914 and 1915,—5,987 in all,—were intensively studied in the light of subsequent experience. This group had an experience of 33,629 years, and showed 217 deaths, as against an expected death loss of 412, according to the American Experience Table,—or an actual mortality rate of 53 per cent. The lower death rate was for practically every age period, the most favorable being from ages forty to sixty, inclusive.

While this was perhaps a select group, as naturally the more intelligent and careful would accept

the offer of the examination, on the other hand, many who elect examination do so because of some symptom from which they may be suffering.

The Metropolitan studied these policyholders critically, and their final opinion was that they had saved in actual dollars and cents from mortality, two for every one they had spent on periodic physical examination.

This striking and definite statistical study, supported by the best clinical opinion as to the value of the periodic examination, should induce each member of the profession to lend the weight of his influence among his friends and patients, and with the public at large, to urge every man, woman, and child to have at least annually a thorough, competent examination.

I trust, also, that this Society may intensively co-operate with the American Medical Association in furthering interest among our members in this field, either through the active work of one of our committees already appointed, or by a special committee, as has been done in other State societies.

In enlarging the routine practice of the periodic physical examination, we shall contribute in no small measure to the great service which our profession is rendering humanity in the maintenance of public health and in the prolongation of human life.

THE BAN ON HEROIN

As long ago as 1917, the Council on Pharmacy and Chemistry deleted heroin from its handbook of Useful Drugs, saying: "The Council holds that heroin has no advantage over morphin; that it has every disadvantage of morphin; and that on the whole its introduction has been harmful, in that it furnished a specious means on the one hand of avoiding the well founded popular fears of morphin by substituting another habit-forming drug." In 1920 the House of Delegates resolved, "that heroin be eliminated from all medicinal preparations; that it should not be administered, prescribed or dispensed; and that the importation, manufacture or sale of heroin should be prohibited in the United States." The recent Congress enacted, June 7, 1924, a bill prohibiting the importation of opium intended for the manufacture of heroin. The Federal Narcotic Control Board has announced that it will not authorize the importation of any opium intended to replace opium or morphin thereafter converted into heroin. This will prevent the open manufacture of heroin in the United States, and as none can be lawfully imported, heroin will soon disappear from the legitimate market.—(*Journal A. M. A.*, Sept. 6, 1924, p. 784.)

BENZYL BENZOATE AND ARTERIAL HYPERTENSION

While the Council on Pharmacy and Chemistry recognizes the existence of honest differences of opinion on many therapeutic questions, and desires to be liberal in its attitude toward all worthy innovations, it refuses to admit claims which are neither in harmony with already accepted facts nor supported by acceptable evidence. The wisdom of this rigorous attitude has been recently demonstrated anew with respect to the widely acclaimed benzyl benzoate. The Council has insisted that its clinical use is still in the experimental stage, despite the alluring announcements of the various alleged virtues of the compound. Benzyl benzoate has, for example, been recommended and doubtless frequently prescribed for reduction of arterial hypertension. A careful clinical study, however, shows that benzyl benzoate, if taken in 25 to 30 drop doses (20 per cent alcoholic solution), has no effect on blood pressure. Furthermore, even continued therapeutic administration over a period of days produced no effect on the blood pressure of patients suffering with hypertension.—(*Journal A. M. A.*, Oct. 11, 1924, p. 1171.)

INDICATIONS AND TREATMENT OF ACUTE SUPPURATIVE MASTOIDITIS*

CARL L. LARSEN, M.D.

St. Paul

The presence of so many discharging ears is a positive indication that active measures have been sadly neglected in the treatment of acute mastoiditis. The production of a chronic running ear should be regarded as a serious offense in preventive medicine.

Even today, in the light of a better knowledge concerning mastoid disease, better laboratory and x-ray facilities, more and better qualified otologists than ever before, chronic ears are still prevalent, which leads the writer to but one conclusion, namely, that many of us err on the side of conservatism.

True, there are undoubtedly fewer discharging ears than existed fifteen and twenty years ago, due to: first, the fact that general practitioners and particularly pediatricians, who see so many of these acute cases, treat them with early free incision of the drum membrane and are capable of recognizing mastoid symptoms and call an otologist when conditions seem warranted; second, early removal of tonsils, adenoids and nasal irregularities; third, better care given the patient's general condition.

Tivnen, in a masterly paper in 1919, says considerable difference of opinion may arise among otologists in the interpretation of the various symptoms encountered in acute mastoiditis but practically all are agreed on the following conditions: (1) that the majority of acute mastoiditis cases are chargeable to an extension of a suppurative otitis media to the mastoid cells; (2) that the majority of suppurative middle ear infections are caused by diseased processes in the nose, throat and naso-pharynx; (3) that a moderate amount of mastoid tenderness and a varying degree of mastoid involvement is present in the majority of cases of acute middle ear suppuration, but this mastoid infection and tenderness, if early and adequate drainage be provided, may, unless other determining symptoms develop, be accepted without alarm for several days and does not during this period

of observation demand a mastoid operation; (4) that in addition to the virulence of the infection and resistance of the patient, the particular build and architecture of the individual mastoid process is an important element in estimating and interpreting the clinical development; (5) that the mastoid of infancy or early childhood is anatomically different from that of the adult—that these anatomical variations are a determining influence in inaugurating and extending such infections, and must be reckoned with in interpreting their particular symptomatology.

In order to better understand and interpret the significance of the various signs and symptoms of this condition, it is essential that we briefly consider the pathology. Three stages are commonly recognized: first, the stage of congestion and exudation of serum; second, the stage of pus production; third, the stage of cell destruction and granulation formation. In the first stage, the mucoperiosteal lining of the cells becomes congested and an inflammatory reaction occurs with exudation of serum; the septa between the cells remain intact; the cells are red and filled with serum tipped with blood. In the second stage, the cells contain pus, the septa being preserved. In the third stage the septa break down, granulations develop, pus is formed in too great a quantity to be drained through the tympanic opening and endeavors to find an exit in the path of least resistance.

The history and general condition of the patient should receive most careful consideration. Inquiry should be made as to previous attacks. Experience has demonstrated that acute suppurative otitis media produced by an acute simple rhinitis or pharyngitis is less likely to involve the mastoid; while if the middle ear suppuration accompanies the exanthemata, diphtheria, septic tonsillitis or influenza, the dangers of mastoid extension are greatly increased.

The ordinary attack of acute suppurative otitis media with adequate drainage usually subsides within two weeks. Prolonged prostration, loss of appetite, anemic appearance, general lassitude and restlessness are all signs that suggest rather more than a simple middle ear infection alone.

The symptoms of mastoiditis may be divided into the following and each one will be discussed individually:

*Read before "Clinic Week," St. Paul, 1923, and the North Dakota Academy of Ophthalmology and Otolaryngology, Grand Forks, May, 1923.

1. Pain.
2. Tenderness on pressure.
3. Temperature.
4. Discharge from the external meatus.
5. Changes in the tissues over the mastoid.
6. Sagging of the postero-superior meatal wall.
7. Changes in the drum membrane.
8. Narrowing of the canal.
9. Blood examination.
10. Bacteriological examination of the aural discharge.
11. Roentgenograms of the mastoid.

Pain.—While not always a prominent symptom, it is in the majority of cases a very important one and should have careful consideration in every case, particularly if it continues after the first few days. Like pain in any diseased condition it varies greatly in different individuals. It depends on the adequacy of drainage, the extent of the mastoid involvement and the severity of the infection. In most cases it is over the mastoid or in the ear, at times radiating upward in the temporal or backward in the occipital region. It may be of a sharp or more often of a dull character. Frontal or temporal headache is not an uncommon symptom. Continuous unilateral radiating pain on the same side as the diseased ear is worthy of consideration. Continued pain, after free drainage has been obtained through the drum head, is an indication of mastoid involvement. I regard with special significance the occurrence of pain on cessation or diminution of the discharge from the middle ear. Undoubtedly pain is a more constant symptom and of more consequence in adult mastoiditis than in children. Absence of pain is not an indication that a mastoiditis is not present. I have not infrequently opened mastoids where a great deal of destruction had taken place but pain had been entirely absent.

Tenderness on Pressure.—According to their relative significance and frequency, Whiting enumerates four tender points: (1) antrum; (2) tip; (3) the point of emergence of the emissary vein; (4) the pre-mastoid lamina or posterior wall of the bony meatus. Tenderness is a very constant subjective symptom and when properly elicited and interpreted is of the greatest significance. Naturally it is more marked in the pneumatic type with thin cortex than in those of the sclerotic type

with thick cortex. I regard recurring tenderness of the utmost importance. In the early stages of acute otitis media tenderness of the mastoid may be present, and if drainage is adequate it usually subsides in two or three days. If it recurs and persists with free drainage, operation is necessary.

Temperature.—Temperature is a very variable symptom and is dependent to some extent on the underlying exciting cause, and we may have little or no temperature and still have an involvement of the mastoid. It is usually higher in infants and children. A recurrence of temperature with free drainage is significant of mastoid involvement and a persistent high temperature, providing drainage is free and no other cause is present, may be the only apparent indication for operation.

Discharge from the external meatus.—The great majority of cases of acute mastoiditis have a discharge from the external meatus. The amount, character and duration of the discharge are important. The quantity of aural discharge is not at the beginning of the disease significant but if it persists for five or six weeks, even in the absence of other symptoms, one must conclude that the antrum and mastoid cells are probably sharing to an appreciable extent in the infection and that the patient should be kept under close observation with the thought of establishing adequate drainage by surgical means. A bloody serous discharge continuing ten days or two weeks, particularly in the adult, is usually characteristic of a severe infection and bears careful watching. If the free drainage abruptly ceases, returning in a few hours or a day or so later, the patient's other symptoms meanwhile exhibiting no improvement, a mastoid involvement is to be apprehended. A profuse discharge continuing for over a week accompanied by other local and general symptoms, particularly if the latter are increasing in severity, are indications for surgical intervention.

This leads the writer to briefly consider the most important point in this discussion. How long are we to allow the aural discharge to continue in the absence of other apparent symptoms?

In children we frequently see dry ears and a normal functioning middle ear after weeks of discharge, but on the other hand, a great many become chronic with the attending dangers of serious complications, the menace of a focal infection and the certainty of impairment of the function of

the middle ear. A persistent discharge in adults is always of more consequence than in children, and a discharge continuing for three or four weeks, even in the absence of other symptoms, frequently accompanies destructive changes in the mastoid, which is demonstrated by roentgenograms and necessitates operation. In children we can often with safety wait a longer time. In many of these cases the suppuration is limited to the middle ear and Eustachian tube and removal of adenoids and diseased tonsils will often bring about a prompt cessation of the discharge. This is particularly true when the middle ear suppuration follows a simple nose and throat infection. Many of our leading otologists believe conservative treatment ought to be limited to three weeks. I do not believe that we can place a definite time limit, but I am sure that we are all agreed that a discharge continuing in children for over three weeks should be kept under close surveillance. Pulsating or pumping discharge in the early stage of acute otitis media is frequently present and is not at this time of particular consequence, but if it continues for two or three weeks, it is important and denotes at least antrum involvement and is then often associated with sagging of the postero-superior meatal wall and an operation is indicated.

Changes in the tissue over the mastoid.—Edema, redness and prominence of the auricle are relatively late manifestations of acute mastoiditis. In the early stages of acute otitis media, these changes are frequently seen but subside in a few days if adequate middle ear drainage is established. In infants and early childhood the changes are often due to the pus penetrating the cortex, producing a subperiosteal abscess. One must always eliminate diseased conditions in the external auditory canal in interpreting the condition. They are much more frequent in children than adults. In Bezold's mastoiditis the swelling is situated below the tip and frequently involves the soft tissues of the neck, caused by the pus penetrating the tip of the mastoid at the digastric fossa. In zygomatic mastoiditis (an involvement of the zygomatic cells) the swelling is high up, extending backward to the occipital and forward to the temporal regions. I have seen several of these cases and in a few was impressed with the relatively few other symptoms that they exhibited.

Sagging of the postero-superior meatal wall.—In the opinion of most otologists this is considered

a pathognomonic sign of mastoid involvement, demanding immediate operation. This symptom unaccompanied by other symptoms, I feel should not be considered too seriously. It can be caused by a filled up antrum which may drain through an adequate drum opening. I have repeatedly seen cases presenting prolapse of the drum clear up under conservative treatment. However, in most cases it is associated with other symptoms rendering the indication for operation comparatively easy.

Changes in the drum membrane.—The drum is usually perforated at some point, or is red, swollen and bulging. We do find an increased number of cases with the drum membrane intact. Here the membrane will not glisten like the normal. It has a dull appearance and the hammer handle will appear narrow. If the perforation is in Shrapnell's membrane it is indicative of an acute exacerbation of a chronic otorrhea. Polypi protruding through the drum opening, I consider an indication for operation. A great many cases of primary mastoiditis without apparent involvement of the middle ear have been reported. Dabney classifies the condition as idiopathic mastoid abscess. He says, "I wish the title to be understood as meaning an abscess in the mastoid process of the temporal bone without any immediately preceding or accompanying inflammatory involvement of the tympanum." Hempstead, of the Mayo Clinic, in a recent article on this subject, in which he reported three cases, says: "The term primary mastoiditis, as it has been designated in the literature, is misleading in such cases, since the infection must be primarily in the mastoid cells, and not secondary to an inflammation of the middle ear that has cleared up. It is possible to conceive of a blood-borne infection, after a severe local injury, as in osteomyelitis of other bones, although there is no more reason to expect such an infection in the mastoid than in other cavities, for example, the accessory sinuses. It is quite probable that some of these cases are latent suppurative otitis media, and not mastoiditis without involvement of the middle ear." He concludes that while the study of these cases does not permit definite conclusions, it indicates the existence of an antecedent otitis media without symptoms.

Narrowing of the canal wall.—In the absence of any inflammatory condition in the canal, this symp-

tom is particularly significant. It is, I believe, more reliable than any other one symptom. It denotes pressure back of the posterior wall.

Blood examinations.—They are not of much value in uncomplicated mastoiditis. A marked increased leukocyte count with an increased polynuclear percentage in conjunction with other confirmatory symptoms is an aid in diagnosis.

Bacteriological examination of the aural discharge.—Most observers regard bacteriological examinations of doubtful diagnostic value. The pneumococcus, Type III, formerly called the streptococcus mucosus, the streptococcus viridans or the streptococcus hemolyticus, are the most virulent and undoubtedly the direct cause of most of the cases of mastoiditis that require operation. I do not see how we can prognosticate from the organism found in the discharge the future course or severity of the disease, this being a question determined by a normal or lowered resistance and by the local diseased process.

Roentgenograms of the mastoid.—There is no doubt that the x-ray when properly taken and correctly interpreted, is in the majority of cases, an aid in diagnosis. Frequently it is the determining factor. I am conscious of the fact that a great many place little or no reliance on the x-ray. In some cases we have not always found what the x-ray apparently demonstrated, in others we were somewhat misled, but in the aggregate our findings corresponded and it has led us to adopt the procedure in all doubtful cases. We have seen many cases that we were convinced had mastoiditis but were unable to convince the physician, patient or parents that such a condition existed, where a roentgenogram verified the diagnosis. However, I much prefer to operate on the clinical symptoms.

Facial paralysis occurring during the course of an acute otitis is an absolute indication for immediate operation.

Gradenigo's symptom, a paresis of the sixth nerve, unless accompanied by other definite clinical symptoms, is not necessarily an indication for operation.

From the foregoing it can readily be seen that the discussion of this important subject is narrowed down to two questions: first, the question of the presence or absence of mastoiditis; second, when should we operate in mastoiditis?

In attempting to answer these questions, the

writer is led to the following conclusions based upon a careful survey of the literature of today and a personal experience in over three hundred cases.

1. Every acute otorrhea should be considered as a potential mastoiditis. The difference is largely one of degree.

2. The majority of cases of acute otitis media do not require operation before the third week because bone softening or decalcification usually requires about three weeks, depending upon the virulence of the infection, the resistance of the patient, the degree of tympanic drainage, and the type of the mastoid bone.

3. Relatively few serious complications follow acute mastoiditis in children caused by the ordinary nose and throat infections. Continued aural discharge in adults is of more serious import.

4. Early operations do not always prevent complications and too early operations may cause complications.

5. Most chronic ears follow the exanthemata (notably scarlet fever and measles), septic tonsillitis and influenza and it is in these cases, particularly following scarlet fever, that the writer urges early mastoid drainage, preventing what is otherwise inevitable, the menace of a discharging foci and the impairment of the function of the middle ear.

6. An acute discharge from the ear should not be allowed to continue for more than six or eight weeks at the utmost, if for no other reason than the impairment to hearing which is so likely to follow.

7. Inasmuch as the laws guiding us in the presence of a given group of indications have been well established for a number of years, only the physician in charge who observes the case from day to day can determine the presence or absence of mastoiditis and can decide the time of operation.

Treatment.—Treatment of acute mastoiditis may be considered under two heads: (1) the treatment of acute mastoiditis including the various abortive measures; (2) the securing of adequate drainage and the extirpation of all diseased conditions by mastoid operation.

Our first aim must of necessity include early and free incision of the drum membrane. If deemed expedient by the surgeon, this can be done under nitrous oxide or ether, or by instilling a few drops

of a mixture containing cocaine hydrochlorate, grains five to ten; alcohol, one dram; anilin oil, one dram.

The incision should be made at the bulging point, extending it upwards and backwards to the posterior meatal wall. This should be followed by a warm, weak antiseptic irrigation. One must remember that bulging of the drum membrane is relatively a late symptom of middle ear suppuration and we should not wait for its appearance before deciding to incise the drum membrane. If the incision is too small it should be enlarged. As a rule I am not in sympathy with repeated incisions because it must be borne in mind that it is not the partially healed incision with retention that accounts for the increase of symptoms, but often it is the increased tension put on the cells of the mastoid that are overfilled with pus, which, from mechanical hindrance, produces the pain, and the increased infection produces the temperature. Almost all the discharging ears that last through life can be traced to a spontaneous perforation. The patient should be put to bed, lying on the affected side, given a laxative, placed on a light diet and every attention given to the general condition. In the early stages an ice bag or heat may be employed. Personally, I prefer cold in the early stages, but the majority of patients, particularly children, are made more comfortable with heat. Politzer states that if the cold eases the pain, the continuation of the inflammation may be assumed; if it proves irritable and unpleasant, then disappearance of the inflammation is probable. Seldom is one obliged to administer sedatives to children. In young adolescents and the adult, I have no hesitancy in employing them, always bearing in mind the fact that the relief thus afforded may tend to mask the symptoms. In the early stages, gentle, warm irrigation with a saturated solution of boric acid, drying well afterward, is not only cleansing but often relieves the pain. After the first few days I favor the dry treatment, mopping the ears dry with cotton-wrapped applicators dipped in borated vaseline, followed by the insertion of a small piece of sterile gauze in the canal to facilitate drainage. The vaseline makes the application less difficult, anoints the canal, thus protecting the skin from the irritating effects of the discharge. Continued irrigations waterlog the drum and to some extent the middle ear, thus favoring suppura-

tion rather than retarding it. I am emphatically opposed to prolonged irrigation.

I realize that in small children, irrigation is more easily administered than mopping, but the former should not be overdone.

Suction is the most efficient means of draining the middle ear. It should be gently and lightly applied two or three times daily.

In children, I doubt the efficacy of any medication to the nose and throat. Many of these children, particularly if they have been susceptible to nasal and throat infection, do splendidly on cod liver oil.

In the Vienna clinics, heat in the form of light, using a high power electric bulb with a condenser, is being universally used, not only in cases of acute otitis media but in early mastoiditis, with most gratifying results. The light is held close to the retro-auricular region from forty-five minutes to one hour the first day, one and one-half hours the second day, and from one and one-half to two hours daily thereafter, preferably half of the time in the morning, the remaining time in the afternoon. I have seen acute otitis media of several weeks' duration clear up very quickly and in acute mastoiditis where operation was apparently indicated, cure was effectively produced in many instances. This form of treatment, too, is very valuable in slow healing wounds following operation. I cannot recommend this valuable adjunct in treatment too highly. There can be no doubt that some of the continuous discharging ears are simply tuborrrhea, the suppuration being confined to the Eustachian tube. This usually responds promptly to removal of nasal conditions, especially the removal of adenoids and diseased tonsils and the correction of the nose-blowing habit. The latter, I feel certain, is responsible for many of our acute and chronic ears. There is too much blowing of the nose. These patients should be instructed to blow the nose without closing either nostril.

I am not an advocate of tonsil and adenoid surgery in the early stage of acute otitis media.

Protein therapy and autovaccinotherapy have not shown the results expected and probably yield their greatest influence in post-operative cases.

Operation.—The technique of the classical simple mastoidectomy, you are all familiar with and requires no elaboration. A sufficiently wide opening made into the antrum to provide adequate

drainage and the careful, clean removal of all diseased cortex are the essential features of the operation. Early healing of the mastoid wound favored by the so-called blood-clot method (the immediate closure of the post-auricular opening) or the removal of drains as early as is compatible with safety are the additional important essentials. The immediate closure of the wound is contraindicated in complicated cases or where the dura or sinus has been exposed.

In these cases we should always remember the law of surgery, namely, that wounds in the process of normal and healthy repair should be subjected to the least possible mechanical disturbance. All dressings should be as light as possible. The outer dressings should be changed in twenty-four hours and daily thereafter. The drain should not be disturbed for four or five days and then gradually removed so as not to disturb the granulations. All bandages should be removed as soon as possible. If the wound shows a great deal of reaction, nothing has given us as much satisfaction as hot, wet boric acid dressings. We have encountered such cases particularly following scarlet fever. I am convinced that the use of wet dressings in this class of cases has been generally neglected. Later on if healing is slow the wound should be exposed to the air and sunlight or radiation.

Causes of failure necessitating a second operation are generally due to too early operation or because diseased cells have been overlooked either in the tip or the zygoma.

In Minnesota in 1921, there was one death in every two hundred and twenty-eight, due to ear diseases. There were twenty-seven deaths attributed directly to mastoiditis.

When we recall that between one-fourth and one-half per cent of all deaths are due to ear diseases, and that between one and two per cent of our population have chronic running ears, I hope that this subject will receive the attention that it so justly deserves.

PLURIGLANDULAR PRODUCTS OF HARROWER

In 1919, the Council on Pharmacy and Chemistry examined a number of the products of the firm of Henry R. Harrower, Glendale, California. It found none acceptable for New and Non-official Remedies. An examination of the "literature" sent out by the firm during the last year shows that its business is still largely in complex mixtures such as those reported on adversely by the Council.—(*Journal A. M. A.*, Oct. 4, 1924, p. 1098.)

Rochester, Minnesota

Fractures of the hip occur at all ages, but are most common in elderly persons. The term, in its broadest sense, may include fractures through the trochanter, but I shall discuss here only those through the neck of the femur, just below the head (sub-capital), through the narrow part of the neck, or at the juncture of the neck and the trochanter. Dislocations of the hip are rare; they occur in persons in the more active period of life, from twenty to fifty years of age. Epiphyseal separations occur generally in children under fifteen years.

The hip-joint, one of the ball and socket type, is firm and stable, owing to the generous depth of the acetabulum, which is increased by the strong cotyloid ligament, to the heavy musculature, and to the fan-shaped arrangement of the muscles, and their insertion close to the joint. Weight-bearing is also a prominent factor in the stability of the hip. The capsule is greatly thickened in certain portions to form strong ligaments, well illustrated by the Y or the femoral ligament on the anterior aspect.

The architectural plan of the neck of the femur shows nature's attempt to strengthen this bridge of bone that is subjected to so much strain. The under part of the neck is the thickest. The elderly person's bones are atrophic and more brittle, and hence give way more frequently than those of the younger person. A cross section shows a system of finely formed bony arches, Gothic in type, thrown across from side to side.

A fracture of the hip is intra-articular, and the synovial fluid that bathes the fractured surfaces of bone is an inhibiting factor in the formation of callus. Delayed union, in the ordinary sense, does not occur in fractures of the hip. The fracture either unites or becomes a case of non-union in a comparatively short time. The proximal fragment is devoid of muscular attachments, and its only source of nourishment is the ligamentum teres and the joint fluid. The capsule of the joint has no

*Read before the Northern Minnesota Medical Association, Duluth, August 4-5, 1924.

attachment to the proximal fragment, except in rare instances in fractures near the trochanter, when there may be a small attachment on the posterior surface. It is apparent that practically all of the reparative process will have to come from the distal fragment. It is very evident also, that in the reduction and setting of such a fracture, the muscular spasm will all be exerted on the distal fragment, and this fragment will have to be manipulated and brought into contact and correct alignment with the upper or proximal fragment. The capsule is strong and reinforced in parts, forming ligaments, and portions of it may, in rare instances, get between the fragments. If this occurs, non-union may be the result in spite of careful and painstaking treatment. When reduction is not satisfactory, open operation should be resorted to. In two instances a few weeks after injury and at-

close to the head and form the group formerly strictly called the intracapsular. On the other hand, if the fracture occurs through direct violence, as the result of a fall on the trochanter, the break is usually through the trochanter, or at its juncture with the neck. In this type a better prognosis may be given than in the sub-capital type, owing to the fact that there is better circulation in the proximal fragment, because of the capsular insertion into it and because usually the patients are younger and in better general condition. When the fracture is through the trochanter, union always occurs, although the position may not be of the best. The only exception I have ever seen was in a case of syphilis of the central nervous system. The signs and symptoms, if the fracture is sub-capital or near the trochanter, are the same, and the differentiation can only be made by aid of the x-ray.

Fig. 1. Measurements used to determine presence or absence of shortening.

tempt at reduction elsewhere, we found the fragments slipped by each other. Clearly under such conditions open operation is necessary.

The Y, or ilio-femoral ligament, is of aid in the reduction of a fracture.

When a reduction is made, and the hip is placed in abduction and extension, this strong ligament becomes taut and acts as a sort of splint in forcing the fragments into alignment, just as do the triceps muscle and tendon in the reduction of supra-condylar fractures of the elbow joint. The exact method or manner of sustaining the fracture varies. Frail, elderly persons may sustain fractures through indirect violence, the fall coming as a result of the break. Such fractures are usually

Disability, even without much pain, following an elderly person's fall on the hip should render the surgeon wary, and unwilling to make a diagnosis of sprain and contusion unless a thorough x-ray examination fails to reveal a fracture. The outstanding subjective symptoms are (1) disability following a fall, and (2) pain of varying degrees on attempted manipulation, or when the limb is used. Instances are not uncommon of the patient's being able to walk for some distance because of the stability of the impaction. The objective symptoms are of more importance: (1) eversion of the leg and foot, (2) shortening of varying degrees, (3) displacement of the trochanter to a posterior plane, always accompanied by eversion of

the foot. (4) crepitus on manipulation, (5) slight swelling and often local tenderness of the hip-joint manifested on palpation, (6) inability, except in firmly impacted fractures, to lift the heel from the bed or table while the knee is extended, and (7) a good x-ray plate or film. The last mentioned will definitely establish the diagnosis, and render unnecessary the manipulation to elicit crepitus.

The absence of the classical clinical signs of fractures of the hip may lead one into the pitfall of mistaken diagnosis if the fracture is well impacted. Time and again have patients presenting themselves with non-union in the hip-joint stated that at the time of the accident their physicians had examined them carefully, measured their legs for comparison of length, then manipulated for crepitus, and because of the absence of these signs had insisted that there was no fracture. Months later, when prolonged disability had demanded further consultation, much to the chagrin of the attending physician, shortening and crepitus had been found, and x-ray examinations had clearly revealed a fracture. The explanation is that there had been good impaction at the time of the accident, but as no fixation was provided, the impaction had broken down. Such cases emphasize the necessity for re-examining at intervals, as one would a patient seen for the first time, if he does not make the recovery anticipated. Measurements are important, and it may not be amiss to emphasize the different ways of accurately taking them. The "real" length is recorded by measuring from the anterosuperior spine to the internal malleolus on both sides. The "apparent" length is obtained by measuring from the umbilicus to the internal malleolus on both sides (Fig. 1). Difference can be made in the apparent length by the patient, by simply tilting the pelvis, but this discrepancy is readily detected by measuring for the actual length. When there is real shortening due to a fracture of the hip, the top of the trochanter will ride above Nelaton's line, an imaginary line drawn from the anterosuperior spine to the tuberosity of the ischium. Also the length of the so-called Bryant's line may be shortened (Fig. 1). This line is obtained by dropping a perpendicular line from the anterosuperior spine to the table with the patient lying on his back. The distance between the top of the greater trochanter and this line will be shortened on the affected side.

We must beware of placing our trust in impaction. Undoubtedly impacted fractures of the hip do sometimes unite firmly with little or no treatment. As I have stated, in a large number of our cases of ununited fractures of the hip a diagnosis of fracture was not made at the time of the accident because there was no appreciable deformity and no shortening demonstrated. In others the treatment had been indifferent and unscientific, carried out more as a ritual, and consisted in applying an ordinary Buck's extension, a long side splint, sand bags on each side of the leg, and so forth. There must be a comprehensive understanding of the pathologic condition present, knowledge of the type of tissue being dealt with, and of the simple mechanics necessary to correct

Fig. 2. Recent fracture of the neck of the femur before reduction.

the deformity. The means to attain the end desired, namely anatomic restoration of the injured part and the fixation in that position until union occurs, may vary according to the method of the surgeon. However, when such surgeons as Royal Whitman and Willis Campbell have had the opportunity to treat a large number of patients with a high percentage of excellent results, it behooves us to follow their teaching and practice their methods, unless circumstances prevent us from so doing, or we have something better to offer. I believe that the abduction method, as advocated so strongly by Whitman, and practiced so successfully on a large number of patients by Campbell, is the

method of choice and should be thoroughly understood by all who undertake the treatment of this serious type of fracture (Figs. 2 and 3). The old belief that the majority of fractures of the hip-joint fail to unite is in the discard, and not to be countenanced in modern surgery. On the other hand, to say that treatment of this sort should be accorded all fractures of the hip is unreasonable. We are all occasionally confronted with the feeble old woman or man of seventy, eighty, or ninety years, whose reserve is almost at the zero point. They are senile, and cerebral arteriosclerosis is advanced. They cannot stand any confinement, and the only thing to do in such a case is to treat the patient and not the fracture. In the past there was too much of a tendency to treat the patient

Fig. 3. Same case as Figure 2 after reduction.

and not the fracture because of the impression entertained both by the profession and the laity that treatment was futile, but in the light of our experiences we now strike a better balance.

The diagnosis of non-union of the hip-joint needs no discussion. The prolonged disability, the shortening, with tendency to eversion of the leg, and, usually the inability to raise the heel from the bed or table with the knee extended, are the cardinal signs. The x-ray discloses the typical lack of union with varying degrees of absorption of the neck. The foot should be in the upright or inverted position when the x-rays are made or there

will appear to be a greater degree of absorption of the neck than really exists.

The treatment of a recent fracture of the hip may be undertaken with confidence, unless the patient is too old or feeble to stand confinement. When possible, the patient should be placed in a hospital, but this is not always done. The emergency is just as great as in most abdominal disorders, and yet a patient with a fractured hip is treated in the home, whereas a patient with an abdominal lesion is rushed to the hospital. Under an anesthetic and preferably on a fracture table, the impaction should be broken up, the leg pulled down to normal length, and the hip swung out into full abduction with the foot in inversion. This reduction is usually readily accomplished, the abduction and inversion maintaining securely the correct anatomic reposition of the fragments. Abduction is checked only by the impingement of the trochanter and its tissues against the wall of the pelvis. Also in this position, while the limb is in extension, the ilio-femoral ligament is tightened, which steadies the fragments. In our hands a double plaster-of-Paris spica cast has been very efficient in maintaining this reduction, but any other agent that answers the purpose may be used. Extension in the abducted position by weight and pulley, or by the Thomas extension splint with means to maintain abduction and inversion, can be used, but the frequent attention necessary is decidedly against either. Bradford has reported several excellent results following the use of his abduction hip splint, primarily designed for the treatment of disease of the hip-joint. I have used it in a few instances as a splint applied after the cast has been worn for from eight to ten weeks. In Minnesota, due to the teachings of the late James E. Moore, the Ruth Maxwell traction method has become more or less popularized, and when properly applied with a full understanding of what is being done, it also affords good results. The chief argument against it is that it requires attention to keep it working properly. That the Whitman method gives good results is shown by the careful report of Willis Campbell, who, in an article based on 160 fresh fractures of the hip, carefully reports his results. Twenty-one patients reported for examination several years after dismissal, but of these, sixteen (75 per cent) had solid bony union, and 90 per cent had good functional results, certainly a different

story from that told by the older practitioners that non-union is to be expected in fractures of the hip.

When non-union exists the patient must either be satisfied with a fibrous union, which in some instances is more satisfactory than might be expected, or have some form of reconstruction operation to bring about union of the fragments or to give bony weight-bearing contact of the femur on

Fig. 4. Non-union of hip with absorption of neck.

the pelvic wall, and thus stability. Each case should be studied separately as to whether or not operation should be undertaken. The age, general condition of the patient, as well as the local condition of the fragments as to the amount of neck left, the viability of the head, and so forth, should all be carefully considered. When possible, after the fragments have been exposed and freshened, the bone pegging or grafting operation is the one preferred because it leaves the anatomic relations more nearly normal. As a rule, the results in patients who have had non-union for a year or less are better than in those who have had it longer. For some time it has been our custom to use the fibula as the graft or peg rather than a piece of the tibia. It is larger and stronger, and the patient never misses it if it is taken out 3 or 4 inches above the external malleolus. Of thirty-six patients operated on by the bone pegging method, twenty-two (61 per cent) obtained bony union.

When the absorption of the neck is almost complete and the fibrous union is inadequate to give a serviceable leg, there are two types of operation to be considered, the Brackett operation and the

Whitman operation. The Brackett operation consists in freshening the surfaces of both fragments and reconstructing the neck of the femur by moving the trochanter with its attached muscles to a lower level on the femur. The denuded end of the distal fragment is put in firm apposition to the raw freshened surface of the head. The hip is then put in the fully abducted position in a plaster-of-Paris cast. The Whitman operation has as its base the removal of the head of the femur and the placement in the acetabulum of the reconstructed neck of the femur as described (Figs. 4 and 5). Each has certain advantages, and in certain patients, if the pain is extreme and the disability great, other things being equal, one of the two latter operations may be undertaken.

SUMMARY

While fractures of the hip do not give the high percentage of good results that other fractures do, they nevertheless respond well to treatment. They should be reduced and held in position until healing occurs, at least three months, with no weight bearing for at least six months. The abduction method, advocated by Whitman, has a sound basis. The teaching that non-union is to be expected is in the discard. Careful examination checked up by measurements and x-ray examinations at the time

Fig. 5. Same case as Figure 4 after Whitman reconstruction operation.

of injury will prevent many mistakes. Re-examination clinically at frequent intervals, if x-rays are not made, will reveal the case in which the impaction breaks down. In case of non-union, the bone pegging operation, preferably using the

fibula, is the most efficacious. When the neck of the femur is practically gone, the reconstruction operations of Brackett and Whitman should be considered. It should be remembered, however, that firm fibrous union in some instances is quite adequate for the demands of function in the declining years of life. Each patient with non-union of the hip presents a problem that can only be solved by individual study.

DISCUSSION

DR. EMIL S. GEIST (Minneapolis): Fracture of the neck of the femur is one of the most serious fractures we have to deal with. The percentage of non-union is still far too high and does not compare at all with any other type of fracture; this even in the face of the Whitman method of treatment, which is pretty well acknowledged to be the best we have to offer up to date in fresh fractures.

The x-ray—even the stereoscopic Roentgenogram—often leaves us in doubt as to whether or not we have achieved that so absolutely necessary desideratum—perfect apposition of the fragments. For without perfect apposition there will be trouble later; either non-union, or a painful hip. We, all of us, have seen cases develop non-union even

when, to judge from all clinical and Roentgenographic evidence, there does exist perfect apposition.

Surely, there must exist some other cause of non-union in this particular kind of fracture besides lack of skill of the physician. Do we not see union the almost universal result in all other fractures, no matter how little the degree of skill employed?

I believe we must look to the synovial fluid for the intrinsic cause of most non-unions of the femoral neck. Witness the old lady of 75 or 80 who breaks the neck of her femur. Personally, I have quit worrying about non-union occurring in her case if she survives the so frequent immediate sequelæ of her fracture (pneumonia, general asthenia, etc.). I have now 8 or 9 such cases, all of whom achieved union—without any treatment excepting rest in bed. Why? I believe it is because there is in these old folks less synovial fluid to interfere with the proper activity of the osteoblasts.

That is why I believe absolute apposition of the fragments is more necessary here than in other types of fracture, i.e., to get away, if possible, from the deleterious effects of the synovial fluid.

Those of us who see many fractures will recall the frequency of non-union in other bones bathed in synovial fluid (head of radius, carpal bones). This idea is by no means original—Cotton has voiced it and others before him.

Absolute apposition is therefore more desirable here than anywhere else in the body. How to achieve it:

Baer, of Baltimore, at the last meeting of the American Orthopedic Association, practically announced his intention of cutting down on all of his (operable) fresh fractures of the neck of the femur and pegging and nailing them because then, as he said: "He knows he has the fragments in apposition and he knows he keeps them there."

I believe that Baer's statement is worth pondering over, for we must adopt some different, radical departure from the methods in vogue today if we are to reduce the percentage of non-union in this so frequent and grave type of lesion.

THE STANDARDIZATION OF DRUGS AMID CHANGING STANDARDS

Medical welfare is hampered in many ways by the machinations of the quack and the health impostor; likewise by the production and distribution of products that are below standard or utterly incapable of accomplishing what the unsuspecting user, be he layman or physician, may rightfully expect of them. Much of the valuable work of the Council on Pharmacy and Chemistry of the American Medical Association consists in revision—in promoting an up-to-date attitude toward well tested novelties in drugs, while preserving a justifiable conservatism toward the valuable contributions of the past. An illustration of the diffi-

culties encountered is afforded by the recent experiences with cod liver oil. The product itself is no novelty, but some of its reputed virtues have been put on a more scientific basis in the last decade. The pharmacopeial standards have been found insufficient. Today it is standardized on its vitamin potency—and more recently on its antirachitic properties. Such tested cod liver oils are widely advertised and have been accepted for inclusion in New and Non-official Remedies by the Council on Pharmacy and Chemistry. Those who believe in keeping abreast of progress should, therefore, lend their enthusiastic support to agencies, such as the council, that labor unselfishly for them.—(*Jour. A. M. A.*, Oct. 4, 1924, p. 1080.)

SOME PHASES OF EPILEPSY*

ERNEST M. HAMMES, M.D.

Associate Professor of Nervous and Mental Diseases,
Medical School, University of Minnesota*St. Paul*

Until recent years epilepsy has been described as a disease characterized by recurrent attacks of convulsions associated with unconsciousness. Many allied conditions have been gradually added, and at present epilepsy is considered merely as a syndrome of some underlying disorder. The old theory that the epileptic convulsion is *always* produced by an explosive discharge of the motor cells of the brain cortex has long been abandoned. This was based mainly on the fact that electric irritation of the cortex produced convulsive seizures. Two other theories have been advanced as to the location of the convulsive site, namely, the combined cortical and subcortical theory, and the medullary theory (Pollock¹). Mingazinni² and others have demonstrated that convulsive seizures are produced in birds by hemorrhage in the pons. Similar observations have been noted in man. Nothnagel believes that general motor irritative phenomena may arise from lesions of the pons alone, while Bechterew states that these are due to indirect irritation of the motor area of the cerebral cortex. However, in decerebrated animals, irritation of the pons produces convulsions, in which the clonic component frequently is absent. On the other hand, Grünwald³ and others have produced typical convulsions in decerebrated dogs and cats by picrotoxin injections. Many similar interesting observations are recorded in the literature. However, no definite location in the brain has as yet been established, which could be termed the convulsive center and which initiates the seizure. It would seem that epileptogenic qualities are possessed by the ganglion cells both of the brain and the brain stem, and that irritation of these cells at any level may produce convulsive attacks.

Fully as interesting and confusing are the various theories advanced as to what makes the individual prone to these periodic convulsions. Toxic factors, both exogenous and endogenous, are given due consideration. Among the former, alcohol heads the list. Endogenous toxins may be pro-

duced locally by the breakdown of cortical tissue in disease, such as arteriosclerosis, general paresis, and other degenerative cerebral disorders. Biochemical substances and endocrine disturbances entering the blood stream are further cited as causative agents. Buscaino⁴ believes that abnormal proteins in the thyroid play an important rôle in many cases of so-called idiopathic epilepsy, and that the convulsions are simply anaphylactic crises. He has demonstrated these proteins in the colloid substance of the thyroid in 71 per cent of epileptics (396 cases) and in only 14 per cent of non-epileptics. He recommends thyroidectomy for these patients. In a study of 128 cases of epilepsy presenting some endocrine disturbance, Patterson⁵ noted evidence of pituitary involvement in an overwhelming majority. Sargent⁶ emphasizes the vascular theory and believes that the vascular disorders produce localized cerebral anemia, which initiates the convulsion. These disorders are due to a disturbance of the sympathetic-autonomic control of the cerebral cortical vessels. Attempts are made to explain traumatic epilepsy on a similar basis. The adhesions between the skull and brain produce traction, if the brain is pulled upon, causing a localized constriction of the cerebral blood vessels and resulting in a localized anemia which precipitates the convulsion. However, in a study of 610 cases of head injuries Holmes and Sargent observed traumatic epilepsy in only 6 per cent, while in a series of 18,000 cases of gun-shot and other head injuries occurring in warfare only 4.5 per cent of epilepsy was noted by Wilson.⁷ Because of this, Wilson hesitates to say that a single case of epilepsy has been caused by a head injury, but feels that the determining agent is an inherited constitutional predisposition to nervous irritability and epilepsy.

In 1917 Terhune⁸ and Reed⁹ published articles on the bacteriological theory of epilepsy. Their findings have not been substantiated by other investigators and were never seriously considered. In recent years L. Pierce Clark¹⁰ suggested the psychogenic factor as a causative agent. He believes that epilepsy is the result of a peculiar personality defect which is constitutional. The epileptic, due to his inability to properly adjust himself to his life's responsibility, reacts by a convulsive seizure. In this way he attempts to escape from distressing situations and unpleasant en-

*Read at the meeting of the Northern Minnesota Medical Association, Duluth, Minn., August 4 and 5, 1924.

vironments. This theory is an interesting one from the psychogenic emotional viewpoint.

Probably the most important causative factor in epilepsy is acidosis (Osnato¹¹). This may depend on a viciously functioning carbohydrate metabolism, causing a general toxicosis, or upon the local production of the toxic substance from disintegrating cellular structures secondary to vascular disturbances. Cuneo has experimentally demonstrated that toxic substances are liberated in the blood by a defect in the alkalization function of the small intestine and liver in the process of carbohydrate metabolism. These toxic substances are capable of causing convulsions when they reach the brain.

The classical syndrome of epilepsy is the grand mal or petit mal attack. However, all its other manifestations are fully as characteristic and significant. Douglas Thom¹² has called attention to the relation between infantile convulsions and the chronic convulsive disorders of later life. In a group of 300 cases studied at the Monson State Hospital for epileptics, 50 per cent had their first convulsion prior to the fourth year. From the records of the Massachusetts General, the Infants' and Children's Hospital, Thom collected 111 cases who had convulsions during the first three years of life. None of these cases were associated with any acute or chronic cerebral condition, birth trauma, or other brain damage. The convulsions occurred with gastro-intestinal disturbances, acute infections, spasmophilia, pertussis, and rickets. In 11 cases no associated disease was noted. Out of these 111 cases 62 patients, or 56 per cent, continued to have convulsions until the time of death, or are having convulsions at the present time or are mentally deficient. Of 29 cases diagnosed as spasmophilia, 16 are similarly affected. These statistics are of special importance when we consider the usual attitude of the general practitioner, and even the pediatrician, toward infantile convulsions. Patrick and Levy¹³ believe that convulsions in infancy and childhood not epileptic, spasmodic or symptomatic of a gross brain lesion, are evidences in themselves of the individual's increased chance of later epilepsy. They¹⁴ further emphasize the importance of slight attacks in young people, such as a transient dreamy state, a momentary stare, a causeless stop in play, a sudden bobbing of the head, a drop to the floor, the youngster at once jumping up, etc.

Similar recurrences are highly suggestive. An occasional nocturnal enuresis, a subconjunctival hemorrhage occurring during sleep, a sore tongue or a confused feeling upon awakening, a small amount of blood on the pillow without demonstrable cause are sufficient evidence to warrant careful observation for nocturnal epilepsy.

A little youngster five years old who had been diagnosed spasmophilia because of three convulsions at the age of two, was referred to us because of nocturnal enuresis occurring about every six weeks during the past eight months. The parents were instructed to have the patient sleep in the same room with them, and about two weeks ago the father was awakened by a grunting noise and found the little youngster in a grand mal attack. Another very interesting observation was that of a bank clerk, aged 23, who consulted us August 15, 1922, because of increasing difficulty with his bookkeeping. His family and personal history were negative except one sister who was under our care for idiopathic epilepsy. He stated that in the spring of 1922 he first noticed that occasionally after a good night's sleep he would feel confused and drowsy. During that day he was unable to concentrate, would make errors in his bookkeeping, lacked interest in his work, and seemed unduly irritable and fault-finding. This was followed by a good night's rest, after which he seemed perfectly normal for a week or so. These distressing periods gradually became more frequent, and about August 1, 1922, he lost his position because of his many errors and general inadaptability. His sister stated that he was becoming very irritable and unreasonable. His neurological examination was negative. He answered questions promptly, but in a rather sullen, resistive manner. He added and multiplied small examples correctly, but seemed confused and made errors when confronted with larger problems. A tentative diagnosis of incipient dementia precox was made, and under a reconstructive regime and rest he gradually improved. After three months he was able to resume his work. His former difficulties soon recurred and he was advised to secure outdoor occupation. About this time one of his sisters residing in a neighboring state informed me that some years previous she had suffered from a condition similar to her brother and that she had been diagnosed nocturnal epilepsy. She made

marked improvement since taking luminal. She requested the same treatment for her brother. He was given two grains of luminal at bedtime and put on a non-stimulating diet. He has made very satisfactory progress and for the past year has been entirely free from his periods of confusion. He is alert and able to fill a responsible position. His irritability has subsided. Although we were unable to obtain any history of epileptic attacks, the irregular periods of confusion, the definite benefit from luminal, and the family history strongly suggest a nocturnal epilepsy.

Epileptic equivalents, especially psychic manifestations, are always interesting and frequently most difficult of diagnosis. Explosions in the mental sphere may manifest themselves in the various forms of psychosis. Furthermore, epileptics present definite mental changes in the course of their recurrent attacks. According to Lewandowsky,¹⁵ these develop in about 85 per cent of all cases. Brill¹⁶ in his recent textbook of psychiatry groups them into three classes, according to the degree: (1) epileptic character; (2) epileptic psychopathic constitution; and (3) epileptic dementia. These patients are frequently unduly irritable, impulsive, moody, passionate, and easily stirred to emotionalism, particularly of a religious nature. Their affectivity reacts in a morbid manner, in that an existing effect lasts a long time and it is difficult to divert it by new impressions, either pleasing or distressing. In many cases psychic functions are markedly retarded and intelligence is below normal. As the seizures recur over a period of years, memory impairment and other evidences of beginning mental deterioration frequently develop.

Epileptic insanity may manifest itself in the most varied forms of psychosis. Mania, melancholia, delirium, stupor, confusional states, paranoid syndromes are all types which may occur on an epileptic psychopathic constitution. Bruce,¹⁷ however, objects to the term epileptic insanity, and believes that the insanity associated with epilepsy is merely an accident.

The psychic equivalent frequently has the same characteristics in its mental explosion as the grand mal seizure, namely, a sudden onset, a rapid subsidence, and no recollection of what occurred during the attack. This is particularly true of the acutely maniacal type and is well illustrated by the following case:

A man, aged 42, was admitted to the neurological service at the Ancker Hospital, November 12, 1922. His friend gave the following history: About 5 P. M., while walking along the street engaged in a friendly conversation, the patient suddenly became violent and excited. When attempts were made to restrain him he became very noisy, attempted to bite and strike his friend. He was overpowered and brought to the hospital in the police ambulance. It was necessary to put him in full restraint, and with the aid of morphine hypodermically he passed a fairly quiet night. Early the following morning, upon awakening, his acute excitement reappeared. He was noisy, abusive, profane, attempted to break his restraints, and talked in an incoherent manner. In about four hours the maniacal condition gradually subsided, but the confusion continued for about two hours. By noon he was apparently normal, requested to be taken out of restraint, inquired as to where he was, how he was brought to the hospital, etc. He had no recollection of what had transpired, but remembered that he had been walking on Sixth Street in the morning with his friend. He was able to give a clear, concise history. His family history was negative. He denied alcohol and venereal disease. For the past twenty years he had been subject to attacks of epilepsy, grand mal type, averaging about ten seizures a year. He had experienced two acutely maniacal attacks similar to the present one. They occurred two years and nine months ago, respectively, and were of about twenty-four hours' duration. He has no recollection of these, but described the attacks from information he received from his friends. The neurological examination was negative. All laboratory tests were normal. In the absence of any other causative factor and with a history of epilepsy, these three acutely maniacal attacks were evidently epileptic equivalents.

Sometimes these sudden mental explosions assume very serious forms and patients commit impulsive acts. This should always be borne in mind when an unusually brutal crime is committed or when an epileptic gets in conflict with the legal authorities because of some unexpected indiscretion against the social order. A young boy, aged 19, devoted to his mother, who was his constant companion, had frequent grand mal attacks. During the interval he seemed apparently normal. On one occasion, while enjoying a meal with his mother, he suddenly grabbed the bread knife, attacked her, and painfully injured her. About six months later, while both were reading, he suddenly jumped up and struck her with the reading lamp. Both of these attacks were of short duration. He had no recollection of what had happened, but manifested great anxiety lest they should recur. He also showed evidences of beginning mental deterioration, a slight memory impairment, and emotional instability.

It is quite characteristic in these epileptic equiva-

lents that the patient has no recollection of what occurs during the attack. Rarely, however, one encounters a case in which the individual realizes what he is doing, but is unable to exercise sufficient control to govern his actions.

A male, aged 18, was referred to me by Dr. W. C. Roberts, Owatonna, Minn., with negative family and personal history except that he has had grand mal attacks for the past six years, averaging about one a month. During the past year he would develop peculiar mental disturbances during which he would threaten to kill himself and the family, would break furniture, etc. During his ten weeks' stay at the hospital he had three such attacks. Without any apparent reason he would suddenly become sullen and depressed, refuse to stay in his room, wander about the hospital and make insulting remarks to the nurses. In one of these attacks he got into an automobile and attempted to start it. When asked to come out of the car and go to his room he became very profane and threw his cap and coat on the ground. After considerable persuasion he finally went to his room. When asked to undress and go to bed he stated that he was unable to make himself do this, that he was getting one of his ugly spells and that he could not control himself. He finally went to bed, but within a short while became noisy, unruly, pounded on the radiator with the soap dish, rattled the door, etc. He finally threatened to harm himself and the nurse. As he became more disturbed it was necessary to put him in restraint. He broke these, smashed the window and the water pitcher, was again put in restraint, gradually quieted down and fell asleep. He awakened the next morning apparently normal and apologized for his actions. He remembered every detail of what had happened. The duration of the attack was about fifteen hours. These attacks bore no relation to his grand mal seizures. In the interval he was normal and a very pleasant and co-operative patient. Because of these dangerous, recurrent attacks, it became necessary to commit him to a hospital for the insane.

Periods of depression, with all the features of a melancholia following an epileptic attack, are not infrequent. They differ somewhat from a true melancholia in that the depression is not so profound nor the state of inhibition so characteristic. Occasionally this condition is observed for a short time prior to the convulsive seizure. The following case is of this character and not only illustrates the depression but also an unusual and prolonged aura:

A girl, twenty years of age, came under observation because of peculiar attacks. Her family and personal history were negative. During the middle of one afternoon she suddenly became quite depressed without any apparent cause. She felt like crying, everything seemed gloomy, and she was very discouraged. The feeling of depression continued and she refused to eat her supper. While retiring, a sudden fear of impending danger came over her for about twenty minutes and then gradually subsided. She began to feel dizzy and attempted to sit up in bed. A small

marble statue of a beautiful person appeared in the room before her. It grew larger and larger, and finally floated toward her, as if it would crush her. She screamed for help, and by the time her sister had rushed upstairs to her room she had entirely recovered. About one month later she had a similar experience, which was followed by a generalized convulsion with involuntary urination. Within six weeks she developed another similar attack.

When one is unable to obtain any previous history of typical grand mal or petit mal it is sometimes quite difficult to arrive at a definite diagnosis of an epileptic equivalent. However, if one recalls the characteristics of this syndrome, namely, a sudden onset, no recollections of what occurs during the attack, and a rapid subsidence of the mental disturbance, frequently followed by a profound sleep, a fairly accurate diagnosis can be made. The following report with a most interesting mental picture is a fairly typical case:

A schoolboy, aged 10, was referred to me by Dr. Meyer, of Melrose, Minn., April 4, 1924, because of an acute mental disturbance. His family history was negative except that a maternal aunt had epilepsy and died in status epilepticus. The mother, a brother, and the patient talked frequently in their sleep, sometimes the greater part of the night. The patient's birth had been normal, and nothing of importance could be obtained in the personal history. Three years ago, while talking to his grandfather, he suddenly screamed, his expression became terrified for about one minute and then became normal. One year later he had a similar attack. On March 17, 1924, while picking up some grain in the barn another boy brought in a rope and told our little patient that unless he worked faster he would hang him, and proceeded to put the rope around the boy's neck. He became terrified and screamed. Within a minute he stiffened out. The mother, hearing his scream, rushed to the barn and found the youngster unconscious and rigid. He recovered in a very short time. After four hours he again met this boy and had a similar attack. After regaining consciousness he was confused, but was able to attend school the following morning. About two weeks later he had similar attacks, as many as three a day. These could be brought on by frightening or scolding him. In the interval he seemed normal. On April 2nd he appeared somewhat confused, acted terrified, requested his mother to remove the pictures of dogs and other animals from his room, because they frightened him. This condition continued until he was brought to my office. While there he would have periods during which he seemed terrified, and evidently had distressing hallucinations of sight, for he would cover his eyes and hide in the corner. At other times he became violent and would bite and scratch whoever attempted to restrain him. This continued for about one hour. During this time he had a short period during which he was quite rational and answered questions promptly and correctly. He was taken to Mounds Park Hospital and within an hour or so the attack subsided and he seemed normal except for some confusion. A diagnosis of epileptic equivalent was made. He was placed

on luminal and under hospital regime gradually improved. While at the hospital he had one generalized convulsion of short duration and several attacks during which he would suddenly fall, be dazed for a minute, and recover. The severity of these mental explosions gradually lessened. One day while visiting with him, his pupils suddenly dilated, his expression became terrified, he screamed and struck about with his arms, then gradually relaxed, fell asleep for several hours and awakened apparently normal. Most of his attacks were followed by a short period of sleep. He would be free from any attack for several weeks. During the interval his mentality was normal except that he seemed unduly affectionate and quite restless.*

Another interesting mental reaction following a series of convulsive seizures occurred in the following case:

A schoolgirl, ten years of age, was referred to me May 10, 1921, by Dr. H. Oerting, of St. Paul, because of epilepsy, grand mal type, and because of attacks of angioneurotic edema. She came from a neurotic family, but had a negative personal history. She had suffered from angioneurotic edema for two years and during the past six months had three grand mal seizures. She was placed on luminal. From May, 1921, till April, 1924, she had only one slight convulsion (February 14, 1924). She discontinued the luminal in March, 1924, and the following month she had four convulsions in one day, one of them occurring while eating her dinner. Following this she developed a fear that if she would eat or drink anything or would talk the convulsions would recur. For three days she did not take a bite of food or a drop of liquid or say anything but yes or no. After considerable persuasion she finally took a little food and some water, while the mother and I were in the room with her. Gradually this fear subsided and she ate and talked normally. However, her mother had to remain with her constantly for over one month because she would become terrified when left alone lest an attack should recur. She refused to leave her home, go for walks or play with other children. Her actions were slow; she required several hours to dress herself or eat a meal. She developed other phobias; she contracted a slight bronchitis with a cough and was convinced that she had tuberculosis. For a few days she was afraid lest she might die from some obscure disease, thought she had syphilis, or might get a stroke. She gradually improved and at present is apparently normal mentally. She has had no further convulsions. Her attacks of angioneurotic edema are continuing, fortunately without any terrifying effect to the patient.

The following case presented a very distressing mental attitude during the development of her epileptic dementia:

A girl, aged 14, who had suffered from frequent grand mal and petit mal attacks for six years, gradually deteriorated mentally. Associated with this she manifested undue jealousy towards her younger sister. She would strike and bite her. Several times she threw dishes at her, would threaten to kill her, and on one occasion attacked her with

a butcher knife. Fortunately her father was present and intervened or she would have seriously injured her. Towards her other playmates and strangers she showed no evidence of this. Under luminal medication her attacks became less frequent and she improved mentally for about one year. Her symptoms recurred and soon after it became necessary to remove her from her home because of the continued threatened attitude towards her sister. Her mental deterioration is progressing.

Epileptic automatism is usually grouped under the head of epileptic equivalents. This frequently occurs during the post-epileptic period and the patient unconsciously performs some unusual act of which he has no recollection afterwards. A discharged soldier, twenty-five years of age, walked out of a store where he had been shopping and had a slight convulsive seizure. He immediately got up, walked into the middle of the street, and proceeded to disrobe. After he was entirely undressed he suddenly seemed to realize what had occurred and ran for shelter. Except for this one attack he had manifested only grand mal seizures over a period of six years.

Another case, a young girl, aged fourteen years, was referred to me because of peculiar hysterical attacks which had occurred at irregular intervals. Her family and personal history were negative. Her mother stated that she had eight attacks during the past year. The patient answered questions promptly but during the course of my examination she developed one of her spells. She became restless for a few minutes, stared, her pupils dilated, she jumped up from her chair, ran to the corner of the room, danced a jig accompanied by bizarre movements of her upper extremities, gradually quieted down, her expression became normal, and she returned to her seat. She had no recollection of what had transpired.

Cases presenting dual personalities with periods of variable duration are frequently considered of an hysterical nature. However, some of these patients have been grouped under the epileptic equivalents and have been called true epileptic flights. The following case is illustrative:

A man, aged 34, was seen in consultation July 2, 1924, and gave the following history of three attacks. His family and personal history were negative. There was no evidence of grand mal or petit mal seizures. The first attack occurred in the spring of 1911 while working on the farm. He disappeared and ten days later suddenly came to and found himself at another farmhouse about one hundred and twenty miles distant. The farmer informed him that he had been there a week and had performed his work

*Since his return home he has remained perfectly well.

properly. He had been rather quiet, but apparently normal. The patient had no recollection of what occurred during the interval. In 1917 he enlisted, saw active front line duty without manifesting any nervous instability. His second attack occurred in the winter of 1920. He was found by some neighbors wandering through the fields in a heavy snow storm. He was dressed lightly, without hat or coat, and seemed confused. He had walked about six miles from home. He was taken home and his confusion gradually subsided. This attack was of about seven hours' duration. He remembered putting his team in the barn about 3 p. m. and had no further recollection until he found himself in bed about 10 p. m. His third attack occurred on March 10, 1924. He drove to town and sold a horse, evidently received a check for it, which he deposited. He remembers selling the horse, but has no recollection of getting a check or anything further until March 30. He suddenly came to and found himself in a depot in Chicago. His clothes were filthy, he had no funds. The station policeman told him that he had been sitting around the depot all day and had acted apparently normal. There was no evidence of any hysterical manifestation in his make-up.

These few case reports and brief gleanings from the literature offer nothing new but were gotten together at the request of several of the physicians who attended the clinic on epilepsy in the short post-graduate course this year where some of these patients were presented.

THE COMMON COLD*

F. W. BRIGGS, M.D.

Duluth

Medical literature of the last decade and more has contained an immense amount of fact and theory concerning foci of infection within the human body. That foci of infection have an intimate etiologic relation to systemic manifestation has been proven repeatedly by clinical and experimental evidence. Many diseases that previously were thought to be due to constitutional disturbances, idiopathic diatheses and dyscrasias are now understood to be complex manifestations of infection.

Primary focalizations of pathologic organisms within the body depend mainly upon two very important factors: (1) the amount and virulence of the invading germs, together with the time over which it extends; (2) the resistance offered by the body at the point of contact. There are other factors, to be sure, which have to do with the body becoming host to these organisms, but it is the resistance offered by the body at the point of contact to which I wish to call your attention.

The relation of persistent foci of infection to secondary manifestations, and to the predisposition to recurrent acute systemic infection is not so generally understood, especially in the upper respiratory tract. However, what I may say regarding this region and organs obtains in all the organs of resistance at the various openings of the body surface, where the skin and mucous membrane meet. W. Stuart Low has recently drawn our attention to the fact that at these vulnerable points of entrance into the body, barrier after barrier of lymphatic tissue have been lavishly and strategically placed—about the anus, vagina, urethra and the nasopharynx. Much confusion and misunderstanding, however, have arisen concerning the primary and secondary foci in the upper respiratory tract. That a primary focus of infection may, and very often does, exist with little or no symptoms is generally understood, and is doubly dangerous to the health and life of the individual, because of this fact. Thus a primary focus of infection within the nose is frequently overlooked and the part it has played is quite covered up by symptoms of pain and distress

*Read before the staff of St. Mary's Hospital, Duluth.

coming from an acute infection within a secondary focus. An inflamed tonsil or an aching tooth or a distressed and painful middle ear are certainly not always primary foci of infection.

In the vast majority of cases these are secondary to nasal infections, established early in life, which as the years pass become silent and chronic, hence easily overlooked in our search for a primary lesion. Thus secondary foci of infection along the pathways of the lymphatics leading from these areas, are often mistaken as primary.

In the open air, nasal infections are of small account in those with normal noses, and those who are already infected are greatly benefited and largely relieved of symptoms referable to the nose by life in the open. When men congregate in buildings nasal infections assume more serious importance, and those whose nasal anatomy is defective are the first to suffer. However, by the removal or treatment of secondary foci of infection resulting from this defective function of the nose, it is quite impossible to expect or to get any permanent improvement or lessen the patient's liability of becoming infected.

About the gallbladder have waged the storms of controversy whether to remove or to drain. Think you that the removal or drainage has much, if any, effect, on the distribution of germs and toxins from the source of infection of which it is a secondary focus.

If the tonsils and adenoids (as many believe) are the primary source of infection, their removal should stop nasal infections; but this is not true. If the teeth are primary, early treating and pulling should stop head colds, but this does not follow. Nasal infections are a distinct entity, and must be regarded as primary. Yet, during all our surgery, necessary and unnecessary, the nose and its dysfunction calls for no investigation on the part of the surgeon or internist. Mentioned in passing, but of momentary and trivial importance, "tonsils and nose negative." Yet, in a high percentage of cases there is a definite history of repeated nasal infections and head colds extending over months, and even years.

In the treatment of septic poisoning of the hand, the removal of the swollen and painful lymphatic glands of the axilla would be analogous to our present-day treatment of swollen and painful tonsils following a nasal infection, either acute or chronic. Tonsillar and adenoid infections are

usually the direct result of mouth breathing, as is also true of a large majority of diseases which enter the body by way of the upper respiratory tract. This relationship, which most certainly exists, is frequently overlooked, often because the patient or his medical advisor has accepted acute or chronic nasal infection as a more or less normal condition, unmindful of the fact that infections within the membranes of the nose are produced by the same germs in the same manner as though infection had entered through, and by way of, an abrasion in the skin. In order that any organ of the body develop and become of some use to its possessor, it must be used. How then can the nose develop and serve its purpose if periodically or constantly it is not used? Here, as in a petri dish, colonies of germs grow and elaborate their toxins, and here as elsewhere in the body anatomy does not develop because of this self-same reason. Hence, in the growing child who is a mouth breather, the nose fails to develop in direct proportion as it is not used and chronic infections result.

A wet nose is usually an infected nose and consequently largely a functionless organ, and is of little value to its possessor. The nose is an organ for warming, moistening, and cleaning the air we inhale. How then can it function or carry out this highly important service with its membranes bathed in mucopus? Or in what manner can the nose function when the nostrils are blocked? Writers, for years, have drawn our attention to the defects of nasal drainage, but why speak of drainage in an organ that is designed to handle air? The observation that para-nasal sinusitis often results from a defective placing of the ostia of the sinuses is obviously incorrect, for the ostia of the sinuses are usually large enough and admirably adapted for ventilation, though very inadequate for drainage, which is an uncalled for function in the normal nose. Drainage operations on the nasal sinuses are sometimes necessary and efficient in pathologic conditions, but so long as drainage persists there can be little, if any, function. A seemingly insignificant nasal discharge that requires but little attention during the winter months is indicative of nasal infection. From this sort of a nose there can easily pass out germs and their toxins to almost any tissue of the body. Certainly, a nose of this type is of little protection to the individual so afflicted. In these cases, mouth breathing does not always obtain, the lower parts of the nose function-

ing, but in the upper and narrower areas liquids accumulate and here germs lodge and develop. From these same areas sinuses become infected which are most certainly secondary to the nasal infection. By drainage of these sinuses, little is ever accomplished of permanent value to the individual.

The prescribing of nasal sprays and douches, together with the employment of ointments and balms for the relief of nasal catarrh, shows appalling ignorance of the function of the nose, or a willful neglect of the principles by which this can be restored.

True it is that tonsils will ever have to be removed, mastoids opened and teeth filled and finally pulled, so long as our noses fail to functionate. For long before the tonsil or mastoid became infected, or the teeth became carious, long before an infected gallbladder gave symptoms of indigestion, or the appendix was the habitat of pathologic germs, that great primary focus of infection of the upper respiratory tract was dysfunctioning and had become the avenue by which these germs gained admission. I am not, however, unmindful of the fact that there are other sources of entrance into the body whereby pathologic germs may, and do, enter, but of the upper respiratory tract the nose is by far the greatest primary focus of infection.

The one great source of nasal infection in the infant is usually the common cold of the nurse or mother. So that our prophylactic measures must begin here. Other than this, abundance of fresh, clean air and life in the open will go far in preventing nasal infections. In the young child with nasal infection, and beginning dysfunction of the nose, the orthodontist is to be consulted early, in order that there may be developed and preserved for future usefulness the vital functions of this highly necessary organ of respiration.

In the adult, surgery of the nose, aside from providing temporary drainage to accumulations of pus, consists of the restoration of normal nasal function, insofar as it can be obtained with the means at our disposal, to the end that air shall freely circulate over and about the turbinates and have easy access to and from the sinuses. Other than this, surgery of this highly important organ is of small account, and merely temporizing.

Pyorrhea alveolaris may not be caused by nasal infections and mouth breathing, but without ques-

tion these are factors which prevent a normal hygiene of the mouth. Someone has said we are becoming the toothless nation; if this is true, we have long since become a noseless nation.

The intimate relationship there is between cause and effect in infectious diseases in the human body is well understood and is worthy of careful consideration. The surgeon or internist who is called upon to treat manifestations of infection within the body will often find a surprising return to health in the patient in whom he has removed or treated a primary focus of infection, and where this is not his concern, either by oversight or neglect, results will ever be disappointing.

That primary foci of infection are often silent, is a well demonstrated fact, and that secondary ones tend in the same direction must be borne in mind. Whenever we disregard the laws pertaining to physiology and normal function, when in our haste we are guilty of overlooking primary foci of infection, nature does not reverse the operation of her laws.

I have but two case records I wish to present at this time:

Mrs. R., aged 51. Present complaint: Nasal catarrh, deafness and discharging ears. The catarrh has persisted as long as she can remember and she has had her ear drums lanced repeatedly with little benefit. Operation: A submucous resection of the nasal septum was performed August 29, 1923. Result: Nasal respiration was re-established and conspicuous benefit to bodily health ensued. The discharge from the ears ceased. No home treatments were permitted. On May 5, 1924, the patient reported herself to be in wonderful health with no nasal or catarrhal trouble, her hearing having largely returned.

Mrs. S., aged 47. Present complaint: Marked deafness, slight nasal catarrh. Patient had scarlet fever at one and a half years of age and ears have discharged off and on since. On examination the patient was unable to hear a watch tick on contact. Operation: A submucous resection of the nasal septum was performed May 26, 1923. At the same time the middle turbinates were broken over. Recovery was uneventful. Result: On examination April 11, 1924, patient was able to hear a watch tick at seven inches with either ear. Nasal respiration had been largely restored. Her general health was greatly improved.

I have selected these cases at random, yet they are typical of this class of cases. Results are not all one could wish, but they have clearly demonstrated that in proportion as we are able to restore normal nasal function, we are able to relieve the patients of distressing symptoms, thereby enabling them again to take their place in society.

BLOOD CHEMISTRY STUDY IN OSTEOGENESIS IMPERFECTA—PRELIMINARY REPORT

ALBERT E. FLAGSTAD, M.D., ELIZABETH ZANGER
and LOGAN LEVEN, A.B.
St. Paul

A considerable amount of literature has been written on osteogenesis imperfecta since the coining of the name by Vrolik in 1845. The majority of these articles have dealt with the gross and microscopic changes in the bone, physical findings, hereditary influence, etiology and prognosis. In 1897 Griffith⁸ called attention to heredity, the age of onset and treatment. He collected 67 cases, 18 of which showed definite hereditary influence. The treatment was mostly experimental. In 1906 Lovett and Nichols¹¹ collected 123 cases. They found hereditary influence in 15 per cent of these. These men made a thorough study of the microscopic changes in the bone. Eddowes⁶ in 1900, Cameron⁴ in 1916, J. B. Alexander¹ in 1922, and H. Stewart¹⁶ in 1922, called attention to the blue sclera and parietal bosses. Cameron also emphasized the curvature and shortenings of the extremities, most marked in the proximal portions. Julius Hess⁹ made an extensive survey of the disease. He called attention to the hereditary factor which is especially more frequent in females. He also included a differential diagnosis of osteogenesis imperfecta, chondro-dystrophia fetalis, cretinism, mongolism, rachitis, infantile scurvy, syphilis, and tuberculosis of bones. In 1916 D. B. Phemister¹³ cited a case under observation four years which was benefited by the administration of phosphorus. The influence of the treatment was followed by x-ray studies of changes in the bone.

Regarding treatment, it is interesting to note that in 1897 Griffith called attention to the fact that it was mostly experimental. What was true then is true today concerning the real etiology and treatment of the disease, for very little progress has been made. Our treatment today is still in the experimental stage. Fortunately, however, the percentage number of cases is very little if any greater than thirty years ago.

In reviewing the literature we find repeatedly allusions to the description of the disease, its etiology, pathology, x-ray changes, and prognosis. We have found only one or two references to the blood

study in this condition. With this in mind a blood chemistry study has been made on these cases and compared with the findings in arthritis deformans, rickets, arthrogryposis congenitalis multiplex and von Recklinghausen's disease.

The primary purpose of this paper is to emphasize this special phase of our study. We feel that, while the number of cases is small, the findings are quite conclusive. It will not be out of place to cite these cases briefly and in so doing call attention to the important factors in each case together with a blood chemistry study of the whole group.

In this paper four cases of osteogenesis imperfecta have been studied, all of which have been

Fig. 1 (Case 1). Showing changes of head, squareness, left parietal boss, deformity of left forearm and lower extremities.

under observation at least three years. During these years a great variety of treatment has been used, such as Alpine light, sun rays, calcium and phosphorus, bone meal, immobilization and supports. In spite of the variety of therapy and the greatest care, multiple fractures have occurred in these individuals, deformity has progressed and, at best, results have been unsatisfactory. Scott¹³

in 1916 reported calcium study in blood and urine of 100 cases of osteomalacia, all of which were in adults and were cases of true osteomalacia, which is very different from osteogenesis imperfecta. Then, too, her method of study of the calcium content in blood has long since been discarded as too erroneous. Tisdall, Howland and Kramer¹⁷ reported a case of osteogenesis imperfecta in which a study of blood calcium was made. Other than this work we have been unable to find references to a blood study in this condition.

CASE 1. A. R. Admitted State Hospital Aug. 5, 1921. Age 13 yrs.

Present complaint.—Bones break frequently.

Family history.—One brother, two half-brothers, two half-sisters, stepfather and mother, living and well; no tuberculosis or cancer; no family traits.

Social history.—Not much schooling because of fractures.

Past history.—Difficult birth; small baby; has had whooping cough, scarlet fever, occasional colds.

Present illness.—Broken bones in arms and legs numerous; began shortly after birth, last fracture July 12, 1923. At least three fractures before admission; one since then.

Physical examination.—Poorly developed; mentality retarded; has brownish pigmentation over body. Head: large, square, irregular parietal bosses above and slightly anterior to ears. Pupils react, sclera quite blue and prominent. Nose flat; mouth and tonsils negative; chest narrow, pigeon breast; spine negative; abdomen negative, except for atonia of muscles; upper extremities, mild deformity of upper one-third of right humerus from old fracture; lower extremities, marked lateral curve of upper third of right femur and fairly marked medial bow of tibia. Leg resembles letter S. Left femur, anterior and posterior curve, and marked knocked knee; tibia and fibula bowed medially.

Laboratory.—Wassermann negative. Blood and urine negative.

Course.—Patient has had three manipulations correcting deformities, the last two being osteoclasia. The bones break very easily, fractures being almost possible by hand. On April 29, 1921, patient broke right humerus while attempting to pull door open. Patient has been on bone meal, has had sun exposure, cod liver oil, but in spite of all therapy his bones remain brittle, and fracture and deformities occur easily. This case presents almost a text-book picture of osteogenesis imperfecta.

CASE 2. A. O. Admitted State Hospital July 24, 1921. Age 2 years 9 months. Scandinavian extraction.

Present complaint.—Repeated fractures and deformities of extremities.

Family history.—No familial tendencies, one brother living and well, mother and father living and well.

Social history.—Born in Minnesota; father mechanic; home conditions good.

Past history.—Birth history negative, breast fed nine months, no childhood diseases, influenza in 1918.

Present illness.—At about four months mother became aware of something being wrong; child was restless and cried a great deal; head became large and square shaped;

developed pot belly. About this time, on very slight trauma sustained a fracture of right humerus, splinted eight weeks and then two months later refractured. In December, 1920, sustained third fracture of right humerus; March 1, 1921, sustained fourth fracture of right humerus;

Fig. 2 (Case 2). Showing deformity of extremities.

in December, 1920, mother noticed deformity of right leg due to fracture; on entrance right arm and forearm in splints and right tibia deformed.

Physical Examination.—Head square, large, irregular, parietal bosses present especially on the right; forehead flattened; fontanelles closed. Eyes, slight blueness of sclera, which are prominent; nose flattened; dentition delayed; neck and glands negative; chest, narrow, pigeon type, Harrison's groove present; heart and lungs negative; abdomen pot type, diastasis recti and general atonia of

Fig. 3 (Case 4). Showing square head, irregularity, flatness of nose, deformity of upper extremities, right clavicle, umbilical hernia, relaxation of the abdominal wall.

abdominal muscles; g. u. negative; upper extremities, marked bowing of both arms confined to humerus. Since patient has been in hospital she has had several fractures of left and right humerus. Deformity of the right clavicle

from old fracture. Lower extremities, marked anterior and slight lateral bowing of right tibia. June 23, 1923, wedge was removed from right tibia to correct deformity and leg remained corrected as long as held in retention apparatus but on removal of support deformity recurred.

Laboratory.—Wassermann, negative. Blood and urine negative.

Course.—December 21, 1921, reduction of fracture of right fibula and tibia. June 23, 1923, osteotomy of right tibia. February 13, 1924, reduction of fracture of clavicle. A number of other fractures have occurred, particularly in the humeri. Retention apparatus has been applied. There seems to be very little pain associated with the fractures. On February 12, 1924, nurse making night round, found patient crying; she complained of pain over right clavicle. X-ray picture revealed a fracture which apparently was sustained in rolling over onto the right side during sleep. The deformity of the right tibia can be corrected by hand

Fig. 4 (Case 2). X-ray of the right arm and forearm showing multiple fractures, also fractures of several ribs.

but it recurs almost immediately on removal of support. Patient has a marked atonia of all muscles, especially of the abdomen. Only recently she has had several very severe prolapses of the rectum. Patient has been on phosphorus, sun exposure and other therapy with little if any benefit.*

CASE 3. I. T. Admitted to State Hospital January, 1921. Age, 15 years.

Present complaint.—Deformities of both lower extremities.

Family history.—Father and mother living and well; five brothers and sisters living and well; one sister similar trouble, otherwise negative.

*Blood chemistry was made and blood values were within normal limits.

Social history.—Born in Minnesota, Scandinavian extraction, home conditions fair.

Past history.—Influenza 1920, otherwise never sick except present illness.

Present illness.—Deformities of extremities noticed shortly after birth. Right femur fractured six years ago; no other fractures; deformity of right knee more marked since fracture; has never walked.

Physical examination.—Undernourished and underdeveloped; head fairly large, somewhat irregular, slightly prominent temporal regions; eyes negative, sclera fairly prominent; nose prominent, not flat; neck negative; chest, heart and lungs negative. A large mass was felt in the lower left and right quadrants not tender. This later demonstrated to be feces, has megalocolon with situs transversus. Upper extremities, shoulder muscles good; flexion deformities of both arms about forty degrees; lower extremities; marked flexion deformities of hips and knees; marked anterior bow of both femurs confined to middle and upper one-third; rectal examination reveals marked deformity of pelvis; sacrum and pubis almost in contact; pelvic outlet about two and one-half inches. X-ray of intestinal tract shows situs transversus, sigmoid in right iliac region and markedly dilated.

Laboratory.—Wassermann, negative. Urine and blood negative.

Course.—This patient has been manipulated several times, has been on heliotherapy and bone meal; in spite of therapy, deformities recur and progress is very slow.

CASE 4. A. T. Admitted State Hospital in 1922. Age 7 years. Sister to Case 3, I. T. First seen at office October 19, 1922.

Present complaint.—Inability to walk, deformity of right leg.

Family history.—Same as Case 3.

Social history.—Same as Case 3.

Past history.—Negative.

Present illness.—Has never walked especially well, but since last summer she has not been able to walk at all; she complained of some pain in region of right hip; no history of injury; leg has become bent and shorter than left.

Physical examination.—Eyes, ears and nose negative; chest, slight Harrison groove; heart and lungs negative; abdomen negative; upper extremities negative; spine negative; lower extremities, right leg is smaller throughout than left and one inch shorter; fairly marked bowing of femur and a large callus can be palpated in region of trochanter major; left leg negative. January 19, 1921, patient was operated upon, subtrochanteric osteotomy (Ghant), cast applied and later several other casts were applied. After a series of casts, leg began to adduct again; about this time developed slight bowing of left tibia. X-ray taken and showed several green-stick fractures. December 9, 1921, x-ray of radius and ulna revealed several fractures. In spite of supports, phosphorus and glandular therapy patient's deformities and fractures continued. In summer of 1922 patient was admitted to State Hospital. Since her stay here she has had several fractures of right femur below site of old Ghant; she also developed marked coxa vara of the hips, especially the right; as soon as patient bears weight deformity follows. Therapy has had little or no beneficial effects.

BLOOD ANALYSIS

A number of determinations were run on three cases of osteogenesis imperfecta, arthritis deformans (2 cases), arthrogryposis congenitalis multiplex (1 case), rickets (1 case), and von Recklinghausen's disease (1 case). The Folin and Wu⁷ system was used in determining sugar, and nitrogenous constituents, including non-protein nitrogen, urea and creatinine. Other methods used included: Benedict's² for uric acid, Clark's⁵ for calcium, and that of Benedict¹² for the determination of phosphorus. Duplicates were run in all cases where the amount of serum permitted.

In the diseases cited above, excepting rickets, there appears to be no significant change in the phosphorus content of the blood, allowance being

In the three cases of osteogenesis imperfecta, the phosphorus and calcium were again determined after the patients had been put on a bone meal diet for a period of one month. There was some variation in the phosphorus content, but no significant increase.

The values for uric acid, creatinine, urea, total non-protein nitrogen, and sugar were within normal limits. Although the urea and total non-protein nitrogen values were, on some occasions,

Fig. 5 (Case 2). X-ray of the right leg showing numerous fractures.

made for the age of the patient and regarding the normal values to be 5 mg. per 100 c.c. serum for children and 3.7 mg. per 100 c.c. serum for adults. In the case of rickets (No. 7), two determinations on blood taken at different times showed low phosphorus values consistently.

Fig. 6 (Case 3). X-ray showing marked curve of the femur and green stick fracture in the lower third.

higher than usual, it could not be regarded as a retention.

Numerous clinical reports of osteogenesis imperfecta are recorded in the literature but very little work has been done on blood analysis. Metabolism experiments in cases of osteogenesis imperfecta by Schwarz and Bass¹⁴ showed nitrogen, calcium, and phosphorus metabolism and fat absorption normal.

Bookman³ found a subnormal calcium retention in three cases of osteogenesis imperfecta.

R. O. Klercker¹⁰ obtained results similar to those of Schwarz and Bass.

As the result of numerous experiments, Tisdall,

Howland and Kramer¹⁷ found that the calcium concentration in serum of children is constant and only altered in two conditions: (1) tetany, and (2) kidney insufficiency with or without nephritis. They found the calcium concentration normal in osteogenesis imperfecta.

SUMMARY

1. In this series were two male and two female cases.
2. Two patients were observed to have characteristic sclera and parietal bosses.
3. Heredity plays a rôle in the series; brother and sister affected.
4. All fractures were of the green-stick variety, and proximal portions were most often affected. Union as a rule was good.

the use of sun and Alpine light, supports when needed, and the prevention and correction of deformities.

Medical Meetings in 1925

At a meeting November 14, at the Nicollet Hotel in Minneapolis, called by Dr. Burnap, president of the Minnesota State Medical Association, representatives of the Northern and Southern Minnesota Medical Associations, the Hennepin and Ramsey County Medical Societies and the Tri-State District Medical Association met and discussed the correlation of medical meetings as to time and place. The co-operation shown at this meeting was most satisfactory. As a result of the discussion, the 1925 state medical meeting is to be combined with Minneapolis Clinic Week and will be held in Minneapolis the last week in April or the first week in May. The date has been advanced from fall to spring so as to avoid conflict with the Interstate Post-Graduate Assembly of the Tri-State Medical Association, which will meet next year in St. Paul, the week of October 26th. This meeting, which is the outgrowth of the Tri-State Association, has, in a way, supplanted the clinical meetings of the Southern Minnesota Medical Association and has shown

a phenomenal growth under the management of Dr. Peck of Milwaukee. Originating as a tri-state meeting, including the states of Illinois, Wisconsin and Iowa, this convention has expanded until now it includes some twenty-two states and its yearly post-graduate course of a week offers clinics to the profession conducted by University professors or associate professors of the highest grade attainable. That the clinics are appreciated is attested by the large attendance at the recent meetings, over 2,700 physicians being registered at the Milwaukee meeting the last week in October. Those who attended the last meeting were for the most part on hand at 7 A. M. and the evening sessions, which lasted usually until 10 P. M., were well patronized. Minnesota is fortunate in having the meeting next October. The Auditorium is ideally adapted for such a large meeting, the large stage affording a sufficient area for exhibits.

One such large clinical meeting being scheduled for St. Paul in 1925, it was deemed advisable to omit the annual St. Paul Clinic Week for next year. The combination of Minneapolis Clinic Week and the state meeting in Minneapolis in the early spring is a happy solution of the division of these two large meetings as to time and place.

The Northern Minnesota Medical Association is scheduled for Brainerd in July, 1925, and the annual meeting of the Southern Minnesota Medical Association, which has been tentatively set for May, will doubtless be changed so as not to conflict with the state meeting.

Minneapolis is to have the National Tuberculosis meeting, June 15. Tuberculosis specialists from all over the United States and Canada are expected to attend the meeting of this national organization.

Minnesota is, so to speak, on the medical map for 1925.

Association Affairs

The Minnesota State Medical Association has shown a steady growth in membership during the last few years, until now we number close to 2,000 members. This places us in the list of the larger state associations.

It is high time that the affairs of our Association were placed in the hands of a member of the profession who is not occupied with the demands of private practice. The argument for a full time

secretary is well presented in a communication which has been sent to each county society secretary by the committee of those appointed by the Council and House of Delegates to investigate and act in the matter. This communication appears elsewhere in this number of MINNESOTA MEDICINE. The subject is a live one and should be discussed by the component societies of our State Association, and the matter of an increase in association dues to meet the increased expense of such a step should not be allowed to drop, but should be acted upon by the House of Delegates at our spring meeting.

A step in the right direction has been taken by the appointment of Dr. E. A. Meyerding, the present executive secretary of the Minnesota Public Health Association, as executive secretary of the Minnesota State Medical Association. He was chosen by the special committee of those above mentioned and his appointment was confirmed by the Councilors present at the meeting called at the Nicollet Hotel in Minneapolis, November 14th. Dr. Meyerding is directly responsible to the Council, receiving his appointment by the Council rather than being elected yearly by the House of Delegates. MINNESOTA MEDICINE offers to Dr. Meyerding its closest co-operation in the furtherance of the work of the Association.

Dr. Everett Geer of St. Paul has been appointed general secretary of the Association for 1925 to replace the present secretary, who again tendered his resignation, effective January 1, 1925.

The death of Dr. F. L. Beckley, treasurer of the Association, necessitated the appointment of his successor. The choice of the Council fell upon Dr. Earle R. Hare of Minneapolis, who through his former secretaryship in the Association is particularly qualified for the position.

A new era in the history of the Association is about to be entered upon and with the co-operation of all our members it should prove to be one of distinct progress.

Increasing the State Society Membership

No one should need to be convinced that every eligible physician should be enrolled in our state society. If there was not the obvious incentive that strength comes with numbers, and mutual advantage with completer contact, we might mention the larger circulation of the Journal, its better resul-

tant advertising rates, and the general lessening of overhead. Presently there is the prospect of getting into line with other states who have secured a properly qualified, whole-time secretary, for their association. With our own membership considerably increased, this would be easier of accomplishment.

Such beneficial increase can only come through direct effort on the part of the officers of our local societies, aided, possibly, by some incentive from our central body. Just what form this should take is a problem for someone to work out. Nevertheless, an analysis of last year's gain of sixty-eight members in the state association is of interest when contrasted with the turn-over of memberships in the St. Louis County Medical Society alone. Secretary Magney reported in November, 1924, that St. Louis County showed a total gain of twenty-six for the year, and a loss of six from death, change of location, etc., leaving a net gain of twenty, or just about thirty per cent of the gain for the entire state. This, even for a large county, is a splendid showing, and due almost entirely to the efforts of the secretary and the very efficient chairman of the special Membership Committee.

This is written to point the way for others to help out in the ultimate increase in our state membership. Make the County Society meetings worth while; make it disadvantageous for any qualified man to either stay out or away.

E. L. T.

MISCELLANEOUS

STATE SECRETARYSHIP

The following letter has been sent out to the secretary of each county society and deals with the matter of a full time secretary for the State Association. Members of the profession are urged to read this to familiarize themselves with this matter.

To the Secretaries of the County Medical Societies:

At the recent meeting of the State Medical Association at St. Cloud a committee from the Board of Councilors was empowered to secure a full-time secretary, with the stipulation that it should be done without immediate increase in the present annual dues. Since it is manifest that the expense incurred will necessitate a slight increase in dues in the future, the House of Delegates believed it advisable to bring the matter up for consideration before the County Societies.

It has been the experience of the seven state associations which have already adopted the plan of having a full-time

secretary that the benefits to the profession derived from this change more than compensate for the increase in dues. We have written to several state associations now employing a full-time secretary, and the answers received are unanimous in approval of the plan. Doctor West, Secretary of the American Medical Association, strongly urges that every state association with a membership of 1,400 or more should have a full-time secretary. He says, furthermore, "There can be little doubt that the association whose business receives the attention of a competent full-time secretary, with that business his only concern, will have decided advantages and will maintain more efficient organization than that one whose executive officer must, of necessity, devote most of his time and energy to his own personal affairs."

In order to meet the demands for better organization of the medical profession for the purpose of solving the various problems confronting us, in order to elevate the standards of our profession, and in order to stimulate co-operation and education of the laity in matters of public health, it will be necessary to employ a man who can devote his entire time and energies in order to accomplish the best results.

I. *State Organization*.—Although the profession in the state is fairly well organized, and much credit should be given to the officers of this association who have helped to make it so, nevertheless, increased organization and closer co-operation are necessary to solve the numerous problems bearing upon the welfare of the profession which are continually arising. According to a recent estimate, there are approximately 600 licensed physicians in Minnesota who are not members of the State Association. In several counties the meetings of the county societies have been allowed to lag and have not maintained the standard which they should. It is evident that a man who could devote part of his time to visiting the various county societies could be of great help to them. By means of personal contact, issuing of bulletins, etc., the work of the individual units would be greatly furthered. Their members would be kept informed as to proposed and passed laws affecting the practice of medicine, as well as on other matters with which they should be familiar.

II. *Closer Co-operation* in the movement to instruct the public in matters pertaining to health. Although we have identified ourselves with several organizations which are ably conducting health instruction campaigns, a closer co-operation on the part of the organized profession would be desirable. In order to bring this about, it would require considerable time and effort and the establishment of an office representing the state association. Active supervision of the increasingly important method of public instruction by means of the radio would come under the province of this office, and would alone require much time and energy in order that the right men should be selected and also that the method would not be subject to ethical criticism.

III. *The Matter of Supervision of Legislation*.—Although this has been ably done by the Committee on Legislation in the past, according to the report read at the last meeting by the committee, they advise securing a man who can devote his entire time to this all-important work. It is easily conceivable that no man who is engaged in private practice can devote the amount of time necessary to successfully carry on this work.

IV. In keeping with the other progressive states, at the recent meeting of the House of Delegates it was recommended that steps should be taken to establish a system of post-graduate education which would be carried to the various centers throughout the state. Similar methods of organized post-graduate study have proven successful in other states. The program includes a schedule of lectures and clinics on live subjects by recognized authorities, to be given in various portions of the state. In this manner the members of the profession are enabled to attend these lectures with a minimum loss of time and expense. In order to carry out this plan, it would be necessary for the state association to be represented by some official who would have sufficient time to keep in touch with the countless details involved in its successful development.

It would be the secretary's duty to secure close co-operation with all of the organizations in the state which are interested in health problems, such as the Bureau of Vital Statistics, State Medical Board, State Nursing Association, Minnesota State Board of Health, Minnesota Health Association, etc. It has long been felt that there should be a closer co-operation between such departments and medical activities carried on in this state. Not only is this desirable from the standpoint of efficiency, but also from the standpoint of economy.

Among the many other functions that a full-time secretary may assume are the following:

As a permanent and full-time officer, he would have the time and experience to be of much assistance in arranging and selecting the scientific program at Annual Meetings. Although most of the committees appointed are conscientious in the discharge of their duties, in many instances they could be made more efficient through the co-operation and stimulus of a full-time secretary. There are other details, too numerous to mention, which only a full-time secretary can successfully handle.

We are sure that every member of the State Medical Association will be back of this movement, which promises much for the benefit of our profession. Our Association has always been known for its progressiveness and it cannot afford to lag behind in the pace set by surrounding states.

Respectfully,

H. M. WORKMAN,

CARL DRAKE,

W. F. BRAASCH, Chairman,
Committee.

THE GORGAS MEMORIAL

During the past year, throughout the United States, the work of organizing the Gorgas Memorial State Governing Committees has been progressing. In some states the response has been most enthusiastic, while in others considerable effort has been necessary to bring home to the doctors the importance of this movement to them, individually and collectively. Inasmuch as the Gorgas Memorial is primarily a medical movement and as such must have the united support of the profession if it is to make the proper impression on the general public, we take this occasion to outline briefly the Gorgas plan and to request the co-operation of our colleagues in bringing to a successful issue this national health program.

We are planning to establish a Memorial for our former chief, Major General William Crawford Gorgas, not of marble or bronze, but a permanent living organization in the form of a great health foundation typical of his work in research and curative medicine, that will unite laymen and doctors in an intelligent effort to obtain better personal health—a health guild that will be supported and directed by the representatives of curative medicine.

The Gorgas Memorial consists of two phases:

1. An Institute in Panama for research in tropical diseases.
2. A health educational program in the United States and other countries that wish to co-operate and participate in the movement.

We are living in an age when people are knocking at all doors of knowledge and demanding that they be admitted. In the field of medicine who are so well fitted to meet this demand as those actually engaged in the practice of medicine? The doctors have a far more interesting and important message to deliver than any other group.

In the United States today there is scarcely a community that has not its quota of irregular "medical practitioners," so-called. In many states there are strong organizations of the representatives of the various cults, whose theories are imposed upon an uninformed public. Public ignorance is encouraged by professional reticence and the result is the astounding growth of unscientific methods. If the profession is to maintain the high standing to which centuries of labor in behalf of suffering mankind entitles it, it is essential that a definite organized effort be made to familiarize the public with such facts as will impress upon it the importance of medicine's contributions to human welfare. A constant fund of proper health information through the newspapers, magazines, lectures, moving pictures and the radio, furnished by medical men and women of known reputation and standing, will direct the public to the proper source for medical advice and gradually eliminate the irregular practices constantly increasing.

One of the objects of the Gorgas Memorial is to furnish a channel through which this kind of information may be disseminated. It cannot be done by individual physicians. It must be conducted by a dignified, ethical organization, controlled by the medical profession. The name of Gorgas is synonymous with "better health." No more appropriate name could be adopted for a movement that has for its object *the development of co-operation between the public and scientific medicine for the purpose of improving health conditions by implanting the idea in the mind of every individual that scientific medicine is the real authority in all health matters and as such should be recognized as the source of health instruction.*

Before we ask the public for financial and moral support, it is essential that the doctors of the country unite in support of this program. As a means to this end, Governing Committees are now in process of organization, on the basis of 100 members to every 1,000,000 population in each state. Seventy-five per cent of the personnel of each Committee will consist of medical men and 25 per cent of influential laymen and women. The permanent activities of the organization will be supervised by these Committees in their respective states, in co-operation with the National Executive Committees.

An organization cannot operate without funds. We are endeavoring to raise an Endowment of \$5,000,000, the interest only of which will be utilized to carry on the work. The principal will be invested in trust securities and remain intact. None of the money thus obtained will be spent for buildings or equipment. The Republic of Panama has donated the site and guaranteed the initial buildings and equipment for the tropical research laboratories, in recognition of Gorgas' great work in Panama. Those invited to serve as Founder members of the State Governing Committees are requested, as they accept membership on the Committee, to subscribe \$100 to the Endowment Fund, payable within two years. Every individual on the State Committee is a contributing member. When the medical nucleus of the organization is complete, a general appeal for funds will be made to the public.

The American Medical Association, at its recent meeting in Chicago, passed the following resolution:

"RESOLVED, That the House of Delegates of the American Medical Association, convinced of the great promise which the Gorgas Memorial contains of benefit to humanity through improved knowledge of preventive medicine and tropical disease, and of its peculiar adequacy, as a tribute to our great leader and sanitarian, recommend to the organized profession of the country, through its constituent state and county societies, the enthusiastic support of the project."

J. A. WITHERSPOON, Tennessee,
JOSEPH RILUS EASTMAN, Indiana,
THOMAS CULLEN, Maryland,
W. H. MAYER, Pennsylvania,
F. B. LUND, Massachusetts.

The Memorial has also been endorsed by numerous other medical and civic organizations.

Every doctor is requested to take a personal interest in the Gorgas program and to see that his community is adequately represented on the State Governing Committee. Each County Society should appoint officially at least one of its members to serve on the State Committee. This is one foundation that is controlled by the practitioners of curative medicine and as such should be supported by every practicing physician. Let us pull together, "the doctor for the doctor."

RED CROSS SEALS

Minnesota's seventeenth annual campaign to raise funds for the 1925 campaign against tuberculosis through the sale of Christmas Seals is now on. In every corner of the state an intensive health educational and fund-raising campaign is in progress. Physicians of the state, who have always been among the most enthusiastic boosters for the Christmas Seal, are enlisted in large numbers in the huge army of volunteer workers. The officers of the state association are: Dr. H. Longstreet Taylor, St. Paul, president; Dr. N. O. Pearce, Minneapolis, vice-president; Mrs. J. A. Thabes, Brainerd, secretary; and W. A. Laidlaw, St. Paul, treasurer. Dr. E. A. Meyerding, St. Paul, is executive secretary.

The Northwestern Health Journal, which was recently endorsed and highly praised by the Minnesota State Medical Association at its annual meeting, is one part of the educational program made possible through the penny Christmas Seals. The 1924 activities of the Minnesota Public Health Association also included the distribution of more than 220,000 pieces of health literature on various subjects; physical examination of more than 4,000 children, a large number of whom were referred to family physicians for treatment of previously-unsuspected bodily disorders; 36 tuberculosis clinics; the enlistment of 40,000 children in the Modern Health Crusade; the planning and display of health exhibits and the services of a Health Clown at county fairs and at the state fair; the partial support of public health nurses in nine counties; health lectures in 44 counties; and an extensive newspaper publicity campaign.

Special educational campaigns for periodic physical examinations, early treatment of physical defects and more abundant use of fresh air were also included in the year's work.

"Buy and Use Christmas Seals" is the clinic slogan for this year, and it is hoped that every letter, Christmas card and package will carry one of the little "for health" stamps.

OBITUARY

DR. HORACE GREELEY MURDOCK, 1858-1924

Horace Greeley Murdock was born at Rensselaer Falls, St. Lawrence Co., New York, on January 10, 1858. He was the son of Dr. Thaddeus and Lucinda Allen Murdock and was the youngest of nine children.

He attended school at Rensselaer Falls and Gouverneur, N. Y., and later went to Oberlin College. He taught school between school sessions for two terms and also studied law a short time but finally decided to follow in the footsteps of his father, three brothers, two uncles and two cousins who were physicians. He entered Rush Medical College, Chicago, and graduated from there Feb. 22, 1881.

He practiced medicine at Glenwood, Minn., for two years.

On Oct. 20, 1881, he was married to Luella M. Daubney, of Taylors Falls. Three children were born to them; Earl, the oldest, was drowned in the St. Croix river, but two daughters survive him. Mrs. Murdock died Sept. 26, 1913.

On January first, 1883, he bought out his brother, Dr. A. J. Murdock, at Taylors Falls, Minn., and practiced there until November, 1919, when he was obliged to give up his work. He worked day and night during the "flu" epidemic and after it was over collapsed. He had been a great sufferer from rheumatism for twenty-five years but in spite of it continued his life work.

On March 31, 1923, he was married to Frances W. Folsom, of Taylors Falls.

He was confined to his home for the last five years of his life but always took a deep interest in the people of the community and many went to him for advice. He had always been a great reader and was deeply interested in all affairs of the day, at home and abroad.

When he first practiced at Taylors Falls there were only three doctors within a radius of forty miles which necessitated long drives in cold and wet weather. He often kept five or six driving horses. The coming of the auto meant much to him.

He died at his home at Taylors Falls, August 3, 1924, of angina pectoris, after a severe illness of two weeks' duration. He is survived by his widow, Frances F. Murdock, two daughters, Beatrix M. Davidson, of Duluth, Minn., and Fannie M. Dike, of Rio Linda, California, and one sister, Mrs. Flora M. Doty, of Rensselaer Falls, New York.

He served as president of the Chisago-Pine County Medical Society for several years. He belonged for many years to that society and also to the Minnesota Medical Association, American Medical Association and the Soo Surgical Association.

He was a member of Zion Lodge A. F. & A. M. at Taylors Falls, and was also a member of the Modern Woodmen of America.

Five Dr. Murdocks practiced at Taylors Falls: Dr. Henry Murdock, a cousin; Dr. Hiram Murdock, an uncle; Dr. George Murdock, a cousin; Dr. A. J. Murdock, a brother; and Dr. H. G. Murdock.

DR. FREDERICK LEE BECKLEY

Dr. F. L. Beckley, widely known St. Paul physician, and president of the Minnesota Transfer State Bank, died at 12:40 P.M. Thursday, October 23, 1924, at St. Joseph's Hospital, following a short illness. He was 53 years old. Dr. Beckley had been in a critical condition since an operation performed the previous Friday.

Dr. Beckley was a native of Minnesota and spent his early boyhood at Paynesville, where he was educated in the public schools. After deciding to follow the medical profession, he entered the University of Minnesota, where he worked his way through the Medical College and was graduated in 1897. After graduation he became associated with Dr. S. G. Cobb, with whom he had lived while at the University. Five years ago Dr. Beckley opened offices with Dr. John Ryan at Prior and Roblyn avenues, St. Paul.

Dr. Beckley was well known as an ardent golfer and was president of the Town and Country Club in 1922-23. He also was a member of the St. Paul Athletic Club, of St. Paul Lodge No. 3, A. F. & A. M., and a Shriner.

Surviving Dr. Beckley are his widow, a brother and sister in California, a brother in North Dakota, and a nephew, Dr. Chester Roche of St. Paul.

REPORTS AND ANNOUNCEMENTS OF SOCIETIES

MINNESOTA PUBLIC HEALTH ASSOCIATION

At the annual meeting of the Minnesota Public Health Association held in St. Paul, November 6, Dr. H. Longstreet Taylor, St. Paul, was re-elected president; Dr. N. O. Pearce, Minneapolis, vice-president; Mrs. J. A. Thabes, Brainerd, secretary; and W. A. Laidlaw, St. Paul, treasurer. Directors were elected for the regular three-year terms.

Dr. E. A. Meyerding, executive secretary, reported the distribution of more than 220,000 pieces of health literature, free physical examinations given to more than 4,000 children, the holding of thirty-six tuberculosis clinics, free lectures in forty-four counties, and public health nursing service in nine counties.

LYMANHURST AND PARKVIEW STAFF MEETING

The regular monthly meeting of the Lymanhurst and Parkview medical staffs will be held at Lymanhurst School, 1800 Chicago Avenue, Minneapolis, Tuesday evening, December 23, at 7:00 o'clock.

Following is the program for the evening:

"Anesthesia in the Tuberculous Patient," Dr. R. E. Farr.

"Surgery of the Genito-Urinary Tract and Chest," Dr. S. R. Maxeiner.

"Surgery of the Abdomen and Lymphatic System," Dr. R. R. Cranmer.

All persons interested in tuberculosis are invited to attend these meetings and participate in the discussions.

OF GENERAL INTEREST

Dr. F. D. Smith, of Kasson, attended the Tri-State Medical meeting at Milwaukee, in November.

Dr. Roy F. Raiter, Cloquet, has returned from a month's visit to the various clinics in New York City.

Mr. David Shepard, St. Paul, has been chosen president of the Board of Trustees of St. Luke's hospital in that city.

Dr. A. K. Stratte, formerly associated with the Northern Pacific Beneficial Association Hospital, is now located at Pine City, Minnesota, where he is doing general practice work.

Miss Anne Toben, daughter of Mrs. Theodore Toben, Duluth, became the bride of Dr. Earl R. Lowe, of South St. Paul, November first. Dr. and Mrs. Lowe are now at home in South St. Paul.

Dr. Harold T. Nesbit has announced the opening of offices at 322-323 Lowry Building, St. Paul, for the practice of his profession. Dr. Nesbit limits his practice to the diseases of infants and children.

Dr. Arthur E. Mark, formerly of the Mayo Clinic, Rochester, and of the Miller and Earl Clinics, St. Paul, has recently moved from Long Beach, California, to Hollywood, where he is located in the Taft Building.

Dr. D. C. Lohead, field secretary and clinician for the Minnesota Public Health Association, has resigned to accept the position of deputy health officer of Rochester, of which city Dr. Charles H. Mayo is health officer.

Dr. J. A. Myers, Minneapolis, read a paper before the Hardin County Medical Society, Eldora, Iowa, the week of November 10. The previous week, Dr. Myers presented a paper before the Trudeau Medical Society, Ann Arbor, Michigan.

Scholarships on the Oliver-Rea Foundation for graduate study in medicine are available at the New York Post-Graduate Medical School and Hospital. Inquiries should be addressed to the Dean, 301 East Twentieth Street, New York City.

Dr. W. E. Belt, of Dodge Center, attended the Violin Makers' Convention at New York last month. The doctor has a completely equipped shop and has been making violins as a hobby for many years. Some of these have been unusually fine and commanded a high price.

Few are acquainted with the existence at Carville, Louisiana, of a National Leprosarium for the care of those afflicted with leprosy in this country. Its present capacity of 211 beds is continually overtaxed, but in the near future facilities will be increased to 415 beds. It is estimated that there are 500 to 1,000 lepers still at large in the United States, who, to a certain degree, are a menace to public health.

The American Chemical Society announces a Prize Essay Contest for the school year 1924-1925, open to high and secondary school students, consisting of six scholarships at Yale University or Vassar College with tuition fees and \$500.00 annually for four years. Six prizes of \$1,000.00 each are offered to college undergraduates in addition to the above. It is not required that students be enrolled in courses of chemistry as the purpose of the contest is to arouse interest in the general subject of chemistry. Information may be obtained from the Secretary of the Committee

on Prize Essays, Alexander Williams, Jr., 85 Beaver Street, New York City, N. Y.

The National Board of Medical Examiners was organized to establish a standard qualifying examination of such character that its certificate of qualification to practice medicine would be accepted by medical licensing boards in all states, and the holder of this certificate be granted a license to practice without further examination. To date its certificate is accepted by 29 states and territories and several foreign countries. The Board aims not only to safeguard and simplify the process of determining those who are qualified to practice medicine, but to aid the medical colleges and state authorities in promoting high standards of medical education and practice. Examinations are open only to students of Class A Medical Schools, which automatically makes it impossible for candidates with fake diplomas to secure its certificate and in this way helps the State Boards in keeping out unqualified practitioners. Examinations were held this year in Minnesota at Fort Snelling. Headquarters are located in Philadelphia.

SMALLPOX

An epidemic of malignant smallpox has recently developed in Minneapolis, fifty-five deaths having been reported from the first of the year to November 18th. The epidemic at this date seemed to be on the increase, 157 cases being under quarantine as compared with 124 a week previous. The total number of cases so far this year has totaled 523.

In St. Paul there have been 688 cases since the first of the year with five deaths reported. It is not generally appreciated that St. Paul has had actually more cases of smallpox this year than Minneapolis. The Minneapolis variety has been much more malignant, however.

The rush for vaccination by the population in both cities has some interesting features. No activity on the part of physicians has been necessary and little has been heard from the anti-vaccinationists. The following facetious editorial appeared in the Fairmont Daily Sentinel, November 15th:

"Someone started the smallpox scare in the Twin Cities. Result, hundreds of thousands are being vaccinated. Meantime word comes from the Rochester clinic that the chief benefit from vaccination is removal of the scare—and of course Rochester is the last word in medical wisdom. It is a great graft for physicians, the charges being all the way from \$2.00 up, according to the quality of your stockings and the size of your diamonds."

The editor forgot to mention that the Health Departments of the Twin Cities have been vaccinating thousands of citizens daily free of charge so that those who consider the usual fee exorbitant can obtain vaccination for nothing. Also no mention is made of the fact that all vaccinations so far have been submitted to voluntarily. The inference derived from the above quotation is that vaccination does not protect against smallpox. The average Twin City citizen apparently does not agree with the worthy editor of the Daily Sentinel, who is nothing loth to display his ignorance of smallpox infection. When smallpox hits Fairmont, as it some day doubtless will, we wonder whether the editor of the Daily Sentinel will be consistent and avoid the immunity afforded by vaccination.

NEW AND NON-OFFICIAL REMEDIES

The following articles have been accepted by the Council on Pharmacy and Chemistry:

BATTLE CREEK FOOD COMPANY:

Lacto-Dextrin

ELI LILLY AND COMPANY:

Pituitary Extract-Lilly (Obstetrical)

Pituitary Extract-Lilly (Obstetrical), 0.5 c.c.

Pituitary Extract-Lilly (Obstetrical), 1 c.c.

Pituitary Extract-Lilly (Surgical)

Pituitary Extract-Lilly (Surgical), 1 c.c.

MEDICAL LABORATORIES, INC.:

Culture Bacillus Acidophilus-Medical Laboratories, Inc.

MERCK AND COMPANY:

Barbital-Merck

Barbital Sodium-Merck

Carbon Tetrachloride-Merck Highest Purity "C.P."

H. K. MULFORD COMPANY:

Cargentos Capsules, 3 grains

Cargentos Ointment, 5 per cent

Diphtheria Toxin-Antitoxin Mixture New Formula
(Park Banzhaf 0.1 L+ Dose)-Mulford

NUTRIVOID DIABETIC FLOUR COMPANY:

Nutrivoid Flour

PARKE, DAVIS AND COMPANY:

Antidysenteric Serum-P. D. and Co., 20 c.c. syringe

POWERS-WEIGHTMAN-ROSENGARTEN COMPANY:

Quinine Ethyl Carbonate-P. W. R.

NEW AND NON-OFFICIAL REMEDIES

Meroxyl.—A mixture containing approximately 50 per cent of the sodium salt of 2,4-dihydroxy-3,5-dihydroxymercibenzenophenone-2-sulphonic acid, with foreign matter containing ammonium 2,4-dihydroxy-benzophenone-2-sulphonate, sodium acetate and water. Meroxyl is a local antiseptic and germicide proposed for use in superficial infections. It is used for wet dressings of wounds, and also for irrigation of wounds and infected bladders. Meroxyl is marketed in the form of tablets containing 0.15 Gm. Hynson, Westcott and Dunning, Baltimore. (Jour. A. M. A., Oct. 4, 1924, p. 1079.)

Metaphen.—Bisacetoxymercuri-4-nitro-2-cresol. It contains from 58 to 60 per cent of mercury in organic combination. Metaphen is a germicide, more powerful than mercuric chloride and certain organic mercury compounds when tested on cultures of *Staphylococcus aureus* and *Bacillus typhosus*. It is stated to be relatively non-irritating when applied to mucous membranes or the skin, and to be without deleterious action on metallic instruments or rubber. Metaphen is proposed for use in the treatment of gonorrhea, infections of the eye, for skin sterilization and for sterilization of instruments and rubber. It is insoluble in water, and, for use, solutions must be prepared with the aid of sodium hydroxide. It is supplied in the form of metaphen solution 1:5,000. Abbott Laboratories, Chicago. (Journal A. M. A., Oct. 11, 1924, p. 1167.)

Sterile Ampules Mercury Benzoate 2 per cent, 1 c.c.—

Mercuric benzoate-N. N. R. (New and Non-official Remedies, 1924, p. 200), 0.02 Gm. (1/3 grain), in a solution of sodium chloride 2.5 per cent, 1 c.c. Swan-Myers Co., Indianapolis.

Sterile Ampules Mercury Succinimide, 0.01 Gm. (1/6 grain).—Mercuric succinimide-N. N. R. (New and Non-official Remedies, 1924, p. 204), 0.01 Gm., in water 1 c.c. Swan-Myers Co., Indianapolis.

Sterile Ampules Mercury Salicylate, 0.065 Gm. (1 grain).—Mercuric salicylate-U. S. P., 0.065 Gm.; benzocaine-N. N. R., 0.02 Gm., in neutral vegetable oil, 1 c.c. Swan-Myers Co., Indianapolis.

Sterile Ampules Mercury Salicylate, 0.097 Gm. (1 1/2 grain).—Mercuric salicylate-U. S. P., 0.097 Gm.; benzocaine-N. N. R., 0.02 Gm., in neutral vegetable oil, 1 c.c. Swan-Myers Co., Indianapolis.

Sterile Ampules Mercury Binioidide, 0.01 Gm. (1/6 grain) in oil.—Red mercuric iodide-U. S. P., 0.01 Gm. suspended in pure cottonseed oil, 1 c.c. Swan-Myers Co., Indianapolis.

Concentrated Tetanus Antitoxin (Globulin).—Tetanus antitoxin, concentrated (New and Non-official Remedies, 1924, p. 297), marketed in packages of one syringe containing 10,000 units; in packages of one syringe containing 20,000 units; in packages of one cylinder containing 5,000 units for intraspinal use; in packages of one cylinder containing 10,000 units with intravenous outfit. Lederle Antitoxin Laboratories, New York.

Antipneumococcus Serum, Type 1.—Antipneumococcus serum (New and Non-official Remedies, 1924, p. 304), marketed in packages of one cylinder containing 100 c.c. with intravenous outfit; in packages of one vial containing 100 c.c. Lederle Antitoxin Laboratories, New York.

Antistreptococcic Serum, Polyvalent.—Antistreptococcic serum (New and Non-official Remedies, 1924, p. 305), marketed in packages of one syringe containing 20 c.c.; in packages of three 10 c.c. vials; in packages of one vial containing 50 c.c.; in packages of one vial containing 100 c.c.; in packages of one cylinder containing 100 c.c. with intravenous outfit. Lederle Antitoxin Laboratories, New York.

Acne Vaccine.—Acne vaccine (New and Non-official Remedies, 1924, p. 316), marketed in packages of four vials containing respectively 5, 10, 20 and 40 million killed acne bacilli; in packages of one 5 c.c. vial containing 40 million killed acne bacilli per c.c.; in packages of one 10 c.c. vial containing 40 million killed acne bacilli per c.c. Lederle Antitoxin Laboratories, New York. (Journal A. M. A., Oct. 18, 1924, p. 1245.)

Staphylococcus Vaccine Polyvalent-Lederle.—Staphylococcus Vaccine (New and Non-official Remedies, 1924, p. 324), marketed in packages of one 5 c.c. vial containing 800 million killed *Staphylococcus albus*, 800 million killed *Staphylococcus aureus* and 400 million killed *Staphylococcus citreus* per c.c.; in packages of one 10 c.c. vial, containing 800 million killed *Staphylococcus albus*, 800 million killed *Staphylococcus aureus* and 400 million killed *Staphylococcus citreus* per c.c. Lederle Antitoxin Laboratories, New York.

Pneumococcus Vaccine Polyvalent-Lederle.—Pneumococcus vaccine (New and Non-official Remedies, 1924, p. 322), marketed in packages of one 5 c.c. vial containing 3,000

million killed pneumococci per c.c. Lederle Antitoxin Laboratories, New York.

Typhoid Vaccine (for prophylactic treatment)-Lederle.—Typhoid vaccine (New and Non-official Remedies, 1924, p. 326), marketed in packages of 30 vials; in packages of one 5 c.c. vial containing 1,000 million killed typhoid bacilli per c.c.; in packages of one 20 c.c. vial containing 1,000 million killed typhoid bacilli per c.c. Lederle Antitoxin Laboratories, New York.

Typhoid combined vaccine prophylactic-Lederle.—Typhoid vaccine (New and Non-official Remedies, 1924, p. 326), marketed in packages of 30 vials; in packages of one 5 c.c. vial; in packages of one 20 c.c. vial. Lederle Antitoxin Laboratories, New York. (Journal A. M. A., Oct. 25, 1924, p. 1335.)

PROPAGANDA FOR REFORM

Some "Mixed" Vaccines of G. H. Sherman Not Accepted for N. N. R.—The Council on Pharmacy and Chemistry reports that the following "mixed" vaccines of the firm of G. H. Sherman were found to be unacceptable for New and Non-official Remedies: Erysipelas Vaccine No. 1, Pneumo. Mixed Vaccine No. 6, Strepto. Staph. Vaccine No. 10, Colon Bacillus Combined Vaccine (Modified Van Cott) No. 35, Friedlander Vaccine No. 36, Influenza Vaccine No. 38, Catarrhal Vaccine No. 40, Whooping Cough Mixed Vaccine No. 43. As evidence for these "mixed" vaccines the firm submitted a printed brochure: "Data on the Use of Mixed Bacterial Vaccines." Part of the data consisted chiefly of the reproduction of letters from physicians—some of them men of high standing—testifying to the value of "mixed" vaccines in various conditions. The other part of the data consisted of abstracts or reprints of articles which have appeared in medical publications. This evidence the Council found unacceptable. The evidence for the several vaccine mixtures under consideration did not establish the rationality of any of them. On the contrary, their use is bound to lead to haphazard therapy—particularly so, because the trend of the Sherman advertising which accompanies the products is toward the use of vaccine mixtures. This includes a complete line of Sherman vaccines and contains a long list of diseases with recommendations for the use of vaccines, generally referred to by numbers rather than by names descriptive of their composition. (Journal A. M. A., Oct. 11, 1924, p. 1184.)

Jack Sprat Bread, Another Obesity Cure Fake.—This bread is put on the market by Charles Sulzer and Co., Chicago, and proclaimed by Sulzer to be "My Magical Discovery." It is said to be "rich in protein" and "unusually low in starch." It is claimed ". . . easily and pleasantly Jack Sprat restores the beauties of form and features." Analysis shows that Jack Sprat Bread has between 29 and 33 per cent of starch and a total carbohydrate content of 36 to 40 per cent. It seems to be a very ordinary product which is a hybrid between a gluten and a whole wheat bread. The statement that the bread is unusually low in starch content is false. It is not true, as claimed, that the obese can reduce by eating all they want, whenever they want it. The claim that "Nothing can reduce you as Jack Sprat will" is sheer quackery. (Journal A. M. A., Oct. 18, 1924, p. 1261.)

PROCEEDINGS OF THE MINNESOTA ACADEMY OF MEDICINE

MEETING OF OCT. 15, 1924

The regular monthly meeting of the Minnesota Academy of Medicine was held at the Town and Country Club on Wednesday evening, October 15, 1924, at 8 p. m. having been postponed one week on account of the meeting of the State Society. The meeting was called to order by the President, Dr. H. P. Ritchie. There were 27 members present.

The minutes of the September meeting were read and approved.

A committee consisting of Drs. Arnold Schwyzer, H. B. Sweetser and John F. Fulton was appointed by the President to draw up suitable resolutions on the death of Dr. Archibald MacLaren, a former president of the Academy.

There were no papers read at this meeting, but the following members reported cases:

DR. HARRY ZIMMERMAN (St. Paul) reported a case of supposed hernia, which at operation proved to be angiosarcoma.

DISCUSSION

DR. A. SCHWYZER: In connection with this interesting case I want to report a case of angiosarcoma in the region of the upper part of the sternum and mediastinum. The man was exceedingly cyanosed and the veins of the neck were distended. He was blue and had had to remain in sitting posture day and night for several weeks. The bulging area was about 10 cm. in diameter and was spongy. At the periphery there were large veins running in all directions. I thought if I could get some radium into the center of that mass I could do most good and save the skin over it. We made a quick incision, packed gauze with 50 milligrams of radium in tightly as quick as the incision was made, but the loss of blood was severe for a short time. We left the radium in the first time only seven hours. A few days later the radium was put in again, this time for 24 hours. When we removed that radium the bleeding was very much less than we had expected though we had entered the sternum with a rongeur forceps at the second session. We waited again about a week and then we went in again, this time through the sternum into the anterior mediastinum. Radium was put in now for 48 hours. The same dose was given two weeks later. It was amazing how that tendency to bleeding had disappeared. He had had in all 8,600 milligram hours. He did very well and went home happy. In fact the condition looked much improved. About three months later he died of what was declared pneumonia.

The effect of radium in angiosarcoma is wonderful, especially if you can get the radium into the center.

DR. R. E. FARR (Minneapolis) reported the following case:

Mr. N. J. L., aged 59, entered St. Mary's Hospital on June 1, 1924, giving the following history:

Left sided hernia for 26 years. About one year ago hernia seemed to disappear for about nine months. Two or three weeks ago patient slipped on a banana peel and immediately noticed bulging in left scrotum. Severe pain for six or seven days. Since that time has had frequent urination day and night with burning. The urine contains a large amount of pus. Patient feels that he empties the

bladder better if he lifts the hernia sac upward, pressing its contents into the abdomen.

June 2, 1924, sacral anesthesia, 70 c.c. of 1 per cent was administered. The bladder was found to contain 75 c.c. of cloudy urine which contained much pus. The bladder was distended with air and with the patient standing a cystogram was made. Cystoscopic examination showed a marked cystitis with a large diverticulum to the left.

On July 17th the patient was operated upon under local anesthesia. The hernia contained nothing excepting the bladder, which was dissected free and returned to the abdomen. The abdominal wall was reconstructed. The radiogram showed the normal contour of the bladder with a compartment about equal to that in the left scrotum. This radiogram was confirmed by one made with sodium bromide solution. A third radiogram shows a sodium bromide cystogram of the bladder after operation. Diverticulum seems to have disappeared—the outline of the bladder being perfectly normal.

DISCUSSION

DR. A. SCHWYZER: Did this come out like a hernia?

DR. FARR: I think this patient had a direct hernia and a diverticulum of the bladder. One point which I did not mention in reporting the case relates to his cystitis. We were unable to overcome his bladder infection by irrigations before operation and yet directly after operation when the bladder emptied completely the infection disappeared.

DR. H. B. SWEETSER (Minneapolis) reported the following case: I would like to report a case which shows that if you have your mind fixed on one thing you may forget the real thing. We had a man who had an abscess of the prostate three or four weeks ago, with a high leucocyte count. We opened the abscess through the perineum. He improved and got along very well for about ten days and then he had a very severe hemorrhage. He went along and was very well again until last Thursday or Friday when he had another quite severe hemorrhage. It saw him then and packed the cavity, and there was just one little spot where the packing was efficient. Early Sunday morning he had another quite severe hemorrhage and when Dr. T. H. Sweetser got down to the hospital the man had already lost a lot of blood.

I had supposed it was like the cases of secondary hemorrhage we had in the old days when I was an intern, due to suppuration.

On Monday morning his mother was at the hospital and she said, "I am a bleeder and my daughter is a bleeder." Also she told us the patient had had his tonsils out about a year ago, and, after he had gone home, he had a hemorrhage which required packing to control.

On Monday we tried to ascertain the bleeding time and let it bleed for 50 minutes and then had to stop it. We gave him 20 c.c. of whole blood under the skin, and yesterday his clotting time was 3 minutes.

I had entirely lost sight of the fact that this might be a case of hemophilia.

DR. H. L. ULRICH (Minneapolis) reported a case of subacute bacterial endocarditis, and showed x-ray films and specimen.

Because of some of the unusual features this case is reported. A Swede, 35 years old, a laborer, some ten months in this country, entered the General Hospital July 18, 1924, complaining of recurrent colds of seven months' standing, fatigability seven months, anorexia two months, occasional chill, and edema of the ankles for one month. There has been no loss of weight.

The past history is practically negative. He had noticed some rheumatic pains in the left hip and shoulder for the past three years, had diphtheria at seven. Denies venereal disease. Family history and social history of no significance.

On entrance his physical examination revealed the following positive findings: some pallor of the skin and mucous membranes, marked pyorrhea, throat injected, tonsils enlarged. Some variation in breath sounds in the right lower chest. Heart is not enlarged, apex beat is forcible and a thrill is felt over this area. Mitral tone is loud and distant, the first being split and roughened. Liver is not enlarged, but the spleen is easily palpable and firm but not tender. Blood pressure 104-50. Temperature 101-99. Blood picture: R. B. C. 3,140,000; hemoglobin 63%, W. B. C. 5,000. P. M. N. 57%, Lymph. 29%, Large mononuclear 9%, eosinophil 1%. Urine amber, acid, specific gravity 1.008, albumen present, no sugar. Hyaline, granular casts, many R. B. C., and a few leucocytes present.

Four days after admission he developed severe abdominal pain and diarrhea. On the fifth day a pustular rash developed on the face and neck, wrists and hands.

Up to this time the tentative diagnosis had been: endocarditis, pulmonary tuberculosis, typhoid fever, tuberculous enteritis, possible T. B. kidney. Owing to the pustular eruption the patient was quarantined as a smallpox subject. The dermatologists, however, made a diagnosis of erythema multiforme. During this period his temperature had been above normal, varying between 102-99. On August 12, some three weeks after his admission, the patient was returned to my service. His temperature had been normal since July 29th. His heart presented a moderate enlargement to the right and left, with a diffuse wavy impulse and a thrill in the fifth interspace inside of the apical area. At the left of the sternum there was a loud harsh diastolic murmur. The spleen was easily felt. Skin of the face was clearing. There was some pigmentation of the face, also of the wrists and hands.

X-ray report of the heart, six-foot plate at about this time: total diameter 15 cm., cardiac enlargement, aortic or hypertension type, probably aortitis. During this period the blood showed the characteristic picture of secondary anemia, hemoglobin from 49% to 38%, reds, 2,800,000 to 2,500,000, leucocytes from 5,000 to 2,700. On August 25th blood chemistry showed: creatinine 2.6 mgms., urea nitrogen 59.9 mgms. Uric acid 6.8 mgms. Van Slyke 40%, Van der Bergh negative. Urine was of low specific gravity, casts, albumen, and R. B. C. present. Blood cultures were repeatedly negative.

The heart was of interest. The major lesion which centered around the aortic valve, the configuration of the heart, and auscultation definitely determined this. Yet there was a marked palpatory thrill inside of the apex, presystolic in time, a presystolic crescendo rumble ending in a snappy

first sound followed by a systolic murmur made some of the clinicians early in the study center the major lesion in the mitral valve. While the aortic lesion was convincing, the stenotic noise and palpatory thrill either spoke for a stenosis of the mitral or a Flint murmur. If a Flint murmur, it was the loudest and most pronounced thrill produced by a Flint ever felt in our wards. Its localization inside of the apex made the suggestion of a Flint more probable than that of a true mitral stenosis. The general condition of the patient meanwhile was fairly good. His appearance improved. He occasionally had a temperature slightly above normal.

The diagnosis of bacterial endocarditis with embolic nephritis was suggested. The absence of bacteria in the blood and at no time petechiæ, are striking factors. On September 11th he developed a severe chill with a temperature of 106. Early September 12th he died.

Necropsy was performed by Dr. Kano Ikeda, of which the following description of findings are excerpted.

A few petechial hemorrhages in the conjunctiva. The peritoneal cavity contains 500 c.c. clear amber fluid. Pleural cavities clear, no adhesions. The pericardial sac contains 100 c.c. clear fluid. The heart weighs 500 grams, transverse width 17 cm., there are a few petechial hemorrhages over the epicardium of the right auricle, the ventricles are dilated. At the aortic orifices the left and right semilunar valves are apparently fused. They are thickened and show irregular yellowish soft vegetations 1x1x2 cm. at the free edges extending downward into the ventricular cavity. There are numerous small vegetative nodules. There is an irregular ulceration of the mural endocardium below the left semilunar valve. The coronaries are patent. The rest of the aorta contains a few yellowish plaques. The lungs are clear. The spleen weighs 730 gms. The capsule is adherent to the surrounding structure. It is tough and shows areas of fibrositis. On section the pulp is dark red and scrapes easily. In the superior pole of the spleen there is an infarct 2 cm. in diameter. The corpuscles are prominent and trabeculae are distinct. The gastrointestinal tract is negative. The pancreas and adrenals are negative. Left kidney weighs 240 gms., the right 230 gms. The capsules strip readily, leaving smooth surfaces with gray and red mottlings. There are minute pin-point dark spots on the surface. On section the surface is mottled, cloudy and swollen. The bladder and genitalia are normal. Head was not examined. Blood culture from the heart negative after three weeks.

Diagnoses: Subacute bacterial endocarditis. Aortic valvulitis. Infarct of spleen—perisplenitis. Cloudy swelling of liver and kidneys. Embolic glomerulonephritis. Ascites. Splenomegaly.

Microscopic sections of the heart through the aortic valve show gram positive cocci, probably streptococci (?). Heart muscle shows diffuse invasion of P. M. N., particularly surrounding the blood vessels, probably embolic myocarditis. Kidneys show diffuse embolic glomerulonephritis. Liver shows early passive congestion. Spleen shows infarcts and passive congestion.

This case differs in certain details from the usual type of subacute bacterial endocarditis. The marked erythematous lesion of the skin, the absence of bacteria in the blood, the

absence of petechiæ until the terminal event are striking. It differs from Libman's aberrant type with skin lesions in that the lesion in the heart is not verrucous, in the absence of pericardial or pleuropericardial lesions and in the absence of petechiæ.*

DISCUSSION

DR. S. E. SWEITZER: This very interesting case reported by Dr. Ulrich came in on the medical side and I first saw him in consultation in the contagious ward, where a diagnosis of phlegmon of the face had been made. He was sent in for smallpox. In one or two days the condition arrived at a stage which showed tremendous edema of the face, including the eyelids, a bullous eruption of the neck, an eruption on the backs of the hands, both large and small lesions. There were hemorrhagic crusts over the nose and around the mouth. Ordinarily we would figure that this man had either a drug rash, smallpox, or erythema multiforme. I had a number of my colleagues see him and each one made a different diagnosis so I stood alone in my diagnosis of erythema multiforme. I thought he had some extreme type due to some virulent organisms. We have long looked upon erythema multiforme as due to various causes. In this particular instance it was septic endocarditis.

While in the contagious ward we placed him on large doses of salicylates and he began to improve immediately. After his skin cleared up sufficiently to send him back to the general ward he did not do so well, and died in about three weeks.

DR. A. SCHWYZER (St. Paul) reported the following case: Dr. Sweetser's case reminds me of a wrong diagnosis I made three weeks ago on a patient. I had thought he had definitely a carcinoma of the stomach. When he was brought into the hospital his hemoglobin was 40. He had bled very copiously from the stomach and intestines and had not been feeling well for two or three months. When you put your hand lightly on the epigastrium you could feel a boggy hard mass about 2 inches wide all the way across the epigastrium, just exactly like carcinoma. It moved with respiration. We wanted to see what we could do for him and made an incision. He had bled so much that we had not dared to take a roentgenogram and thought an exploratory operation would be the best to help us out.

Under local anesthesia we opened the abdomen. The small intestines were pale and flabby, but there was one very dark red, almost black, small intestinal loop. Its peritoneal covering was not glossy any more but somewhat roughened. There were in the corresponding mesentery little streaks of blood and the whole loop felt fleshy and thick. We had here undoubtedly a thrombosis but not a large complete infarct. About 2 cm. away from the gut the mesentery was normal. The attachment of the mesentery was dark red and thick. In pulling down the omentum we found the whole transverse colon big, thick and solid, dark red, but not completely black. No marked edema with it. The surface was not shiny as it is normally. The whole colon was firm and this was the mass we had felt. At the periphery of this area there were streaks of suffusion. About 3 cm. down on the transverse mesocolon the discoloration

ceased. On the stomach itself there was nothing to be seen except on the greater curvature a few small subperitoneal hemorrhages. Apparently we had only small but multiple radicular thromboses in these areas of the portal system.

We closed the abdomen up and gave him Bulgarian sour milk. He had to have something, as he had been starved for 3 or 4 days before entering the hospital. The recovery was surprisingly smooth. The patient is all right now. I thought this was interesting, for the infarction was not only in the transverse colon but also in the loop of jejunum. There had been no fever. It was a degree of infarction which, notwithstanding the marked palpatory findings and discolorations, did not completely obstruct the circulation. Small nicks with the knife had shown bleeding.

I might add that the black vomit after operations, especially on the omentum, is also considered to be due to this form of radicular thrombosis in the portal system.

The meeting adjourned.

JOHN E. HYNES, M.D.,
Secretary.

- ORGANOTHERAPY IN GENERAL PRACTICE.** 253 pages. Illustrated. New York: G. W. Carnrick Co., 1924. \$2.00.
- This volume has been put out by the G. W. Carnrick Company, of New York City, and is offered to the profession. The author's name is conspicuous by its absence. An anonymous volume of any kind lacks authority and when it is produced by a commercial house it is naturally received with hesitation, to say the least.
- The following appears under the heading "Insulin in Treatment": "For the routine treatment of diabetes of the mild or moderately developed type, extending over years, the daily or twice daily injection of an expensive product has failed to meet the requirements. Oral administration appears to be the only satisfactory method for this long continued treatment in the home. Numerous extracts have been prepared for oral administration and have proved successful in reducing blood sugar and correcting disturbed carbohydrate metabolism. Berkeley, Wallis, Achard and others have prepared extracts which gave good results clinically and Banting and Best and Murlin have given experimental evidence of the value of such extracts by administration through the stomach. No pancreas preparation, however, has received as extensive clinical trial as Trypsogen."
- The occurrence of such an obviously unfounded statement in a work of this sort further discredits the entire volume. Physicians and not commercial houses should be the authorities on therapeutics.
- C. B. DRAKE, M.D.

ULTRA-MODERN HOME in Lynnhurst district, Minneapolis, formerly occupied by physician and ideal for member of medical profession, will be sacrificed if sold this month by out-of-town owner. On corner lot, with beautiful lawn, trees and shrubbery, home is eight-room tapestry brick and kragstone bungalow. First floor has large living room, brick fireplace, built-in features; large dining room with built-in buffet; two large bedrooms, French windows; breakfast room with French windows on three sides; white enamel kitchen and gas and coal combination range; large porch with pagoda roof. Basement has amusement room, daylight laundry, separate work, vegetable, boiler and coal rooms, and fireproof garage. Hot water heating system. Upstairs has large guest room, maid's room, washroom with running water. For information or appointment, call Mr. Kaufman, Main 1798, or write H. H. Kaufman, 1606 Oliver Ave. N., Minneapolis.

THE MINNEAPOLIS GENERAL HOSPITAL offers a Technician's Course in x-ray to women having high school diplomas. Course covers a period of eight months. Diploma is issued upon completion of the course. Noon meal furnished. Address Minneapolis General Hospital, Minneapolis, Minn.

McDANNOLD SURGICAL CHAIR—Send for circular and big discount. A. McDannold Chair Co., 1416-18 N. Sarah St., St. Louis, Mo.

A PRACTICAL COURSE IN STANDARDIZED PHYSIOTHERAPY, under auspices of Biophysical Research Department of Victor X-Ray Corporation, is now available to physicians. Offers a highly practical knowledge of all the fundamental principles that go to make up the standards of modern scientific physiotherapeutic work. Course requires one week's time. For further information apply to J. F. Wainwright, Registrar, 236 South Robey Street, Chicago, Ill.

EXCELLENT LOCATION for physician in new building at 3805 Nicollet avenue, Minneapolis. Fine new heated apartment, four rooms and bath, can be had in conjunction. Reception room with dentist. For information call Colfax 2754.

WANTED—To buy an unopposed practice in Minnesota by a physician and surgeon. Address C-9, care MINNESOTA MEDICINE.

MEDICAL DOCTOR WANTED at once in city of 4,000 population. Community hospital, good territory. For particulars write Mlinar Drug Store, Hutchinson, Minn.

MINNEAPOLIS OFFICE SPACE TO SUBLET—Very desirable office space at 323 La Salle Bldg., Minneapolis, to be sublet by Drs. Willson, Cabot and Wohlrahe. For information call at office or telephone Main 3220.

Minnesota State Medical Association

ANNUAL MEETING

October 8, 9 and 10, 1924

ST. CLOUD, MINNESOTA

MINNESOTA STATE MEDICAL ASSOCIATION
MINUTES OF THE FIFTY-SIXTH ANNUAL
MEETING HELD IN ST. CLOUD, OCTOBER
8, 9 AND 10, 1924

PROCEEDINGS OF HOUSE OF DELEGATES

FIRST SESSION—WEDNESDAY, OCTOBER 8, 1924

The House of Delegates held its first meeting Wednesday afternoon in the Knights of Columbus Hall, with the First Vice President, Dr. E. T. Sanderson, Minneota, in the chair.

THE CHAIRMAN: You will please come to order while Dr. Drake reads a communication from Dr. MacLaren, our President.

THE SECRETARY: The following is a communication which Dr. MacLaren asked to be read before the meeting of the State Association:

It is with feelings of the deepest regret that I find it will be impossible for me to attend the meeting of the Minnesota State Medical Association at St. Cloud. Never having suffered from a severe illness before, it has seemed, from week to week, that I would surely be able to be with you at this time. In this hope, however, I am doomed to disappointment in spite of the excellent care given me by my skillful medical advisors. They assure me that before long I shall be out again and then it will be with the most heartfelt pleasure that I shall greet my old friends again. I wish to express, at this time, my keenest interest in the meeting and to send to you my best wishes for its great success.

DR. ARCHIBALD MACLAREN.

THE CHAIRMAN: I will appoint a committee to pass on the credentials of delegates: Dr. Condit, Dr. Braasch, and Dr. Gray; and we will stand at ease until the Credentials Committee reports.

(Upon motion, duly seconded and carried, the Minutes of the last meeting of the House of Delegates as published in MINNESOTA MEDICINE in the December, 1923, issue were accepted.)

THE CHAIRMAN: I will call upon Dr. Workman to present the recommendations of the Council and the Treasurer's Report incorporated in the Report of the Auditors of the accounts of the Association.

REPORT OF THE COUNCIL

The Council of the Minnesota State Medical Association convened at 11 o'clock, October 8, 1924, in the Knights of Columbus Club Rooms, St. Cloud, Dr. W. H. Workman, president of the Council, presiding. All members with the exception of Dr. Weiser, who was absent on account of illness, were present. Dr. E. T. Sanderson, first vice president, attended in the capacity of president in place of Dr.

Archibald MacLaren, and Dr. Carl B. Drake, secretary, was also present.

Dr. E. T. Sanderson was authorized to preside at the various meetings of the Association during the time of the convention to take the place of Dr. MacLaren, who was unable to attend because of illness. A communication from Dr. MacLaren was then read.

It was voted to approve the expenditure of \$175.00 in payment of expenses incurred in presenting a health exhibit at the 1924 State Fair, held in St. Paul in September.

The report of the Executive Secretary, which included the report of the auditor, Mr. Flesher, was then given by Mr. Bruce. This was followed by the report of the treasurer, Dr. F. L. Beckley. Both reports were approved by the Council, to be published with the regular transactions of the meeting.

The question of whether or not the Society should continue to give medical defense to members of the Association was discussed, but no definite action was taken on the matter.

Dr. Braasch then introduced the question of providing for a full time executive secretary, who would receive a definite salary for handling the affairs of the Association, to devote all his time to the interests of the Association. Upon motion to that effect, the president of the Council was asked to appoint a committee, to include himself, of three members, to bring this matter before the House of Delegates. Dr. Workman then appointed Dr. Braasch and Dr. Drake to act in conjunction with himself in this capacity.

Dr. Drake read the Secretary's report in which he included his resignation as secretary to become effective at the close of the present calendar year. The report was approved and Dr. Drake's resignation was accepted with an appreciation of his services for the past four years, which was voiced in the form of a motion made to the Council by Dr. Braasch.

Dr. Burnap then presented the matter of physicians' accepting contract fees from organizations for medical service rendered individuals belonging to such organizations, dealing particularly with the question raised by the Red River Valley Medical Society with respect to the Order of Eagles. It was recommended that the individual local medical societies adjust matters of this kind as they deemed best in each case brought to their attention. The motion was seconded and carried.

The matter of providing for physicians who have become incapacitated or are in straightened circumstances was brought before the Council by Dr. Drake. It was the consensus of opinion that this matter should be taken up with the House of Delegates.

The question of providing a circulating medical library for the use of the profession in the state was discussed but no action was taken inasmuch as the president stated that plans were now being made at the State University which would undoubtedly take care of an arrangement of this nature.

The Council then adjourned to meet immediately after the House of Delegates, Thursday morning.

H. M. WORKMAN.

REPORT OF THE AUDITORS
MINNESOTA STATE MEDICAL ASSOCIATION
SAINT PAUL, MINNESOTA

AUDIT REPORT
OCTOBER 10, 1923, TO OCTOBER 4, 1924

October 6, 1924.

Minnesota State Medical Association,
J. R. Bruce, Secretary,
Saint Paul, Minnesota.
Gentlemen:

In accordance with your request, we have made a Balance Sheet audit of the books and records of the Minnesota State Medical Association for the period October 10, 1923, to October 4, 1924, and we present our report in the following Exhibits and accompanying comments:

- EXHIBIT A—STATEMENT OF ASSETS, LIABILITIES AND NET WORTH AS OF OCTOBER 4, 1924.
- EXHIBIT B—STATEMENT OF INCOME AND PROFIT AND LOSS FOR THE PERIOD OCTOBER 10, 1923, TO OCTOBER 4, 1924.
- EXHIBIT C—TREASURER'S REPORT OF THE CASH RECEIPTS AND DISBURSEMENTS FOR THE PERIOD OCTOBER 10, 1923, TO OCTOBER 4, 1924.
- EXHIBIT D—STATEMENT OF OPERATIONS OF MINNESOTA MEDICINE PUBLICATION, OCTOBER 10, 1923, TO OCTOBER 4, 1924.

The above statements were prepared from your books, and the items on the Balance Sheet were verified by actual inspection in the case of the bonds, a check of the bank statements, and a verification of the accounts receivable. A list of the accounts receivable was furnished us and the executive secretary advised all the accounts were considered good and collectible.

On account of the short time allotted for this audit, it was deemed best not to insist on a physical inspection of the Northern Pacific Bonds shown on the Balance Sheet at \$4,000.00, as they were in a safety deposit box in a bank considerably removed from the office of the Treasurer, although he stated, if we so desired, he would secure them for our examination.

The accrued salaries payable consist of salaries due two of the officers of the association, which were not paid due to an oversight. All other liabilities have been paid.

EXHIBIT A—BALANCE SHEET: This statement sets forth the financial condition of the Association as of October 4, 1924. The Net Worth of the Association has increased from \$14,320.27 October 10, 1923, to \$14,845.00 October 4, 1924.

EXHIBIT B—STATEMENT OF INCOME AND PROFIT AND LOSS: This statement shows the result of operations of the Association for the period under review, whether or not the receipts or expenses have actually been paid out in cash. This was not possible last year, as the books were not on a double entry and accrual basis. It is now possible to show actual results.

EXHIBIT C—TREASURER'S REPORT: This statement shows the actual cash receipts and disbursements made by the Treasurer during the year, and the balance of cash on hand October 4, 1924.

EXHIBIT D—STATEMENT OF OPERATIONS OF THE MINNESOTA MEDICINE PUBLICATION: This statement is compiled for the purpose of showing the financial result of operations of the Magazine, "MINNESOTA MEDICINE." Inasmuch as members do not pay directly for a subscription to the magazine, an amount of \$2.00 per member is allotted to the magazine to show the revenue it is entitled to from subscriptions.

WE HEREBY CERTIFY, That subject to the above comments, in our opinion the Balance Sheet, Exhibit A, presents the true financial condition of the Association at October 4, 1924, and the Income and Profit and Loss State-

ment shows the true result of operations for the period under review.

Respectfully submitted,
FLESHER, FLESHER & COMPANY,
(Seal) By BENJ. H. FLESHER.

THE CHAIRMAN: Inasmuch as 20 constitute a quorum, we will declare the house duly constituted and will proceed with the business of the day. What will you do with the Auditors' Report?

(Upon motion, duly seconded and carried, the Report was accepted.)

THE CHAIRMAN: We will have the Secretary's Report, general and executive.

The Secretary read the following report:

SECRETARY'S REPORT

The active membership of the Association this date is 1,952. In addition to these, dues have been received from thirteen members, who have died during the year. There are also four honorary members. This makes a net gain of sixty-eight members over the membership reported a year ago. Following is a list of the membership by societies:

Aitkin County	6
Blue Earth County	32
Blue Earth Valley	24
Camp Release District.....	42
Central Minnesota District	16
Chisago-Pine County	15
Clay-Becker County	25
Dodge County	9

Washington County	14
Watonswan County	7
West Central	23
Winona County	20
Wright County	17

Total net membership (13 deceased)1,952
Grand total1,965

Legal expenses have been increasing from year to year and this year totaled \$3,739.25, which is about \$1,000.00 more than last year. Below is a statement of the amounts paid in each of the actions:

Doran vs. Mankato Clinic	\$ 77.00
Hadd vs. Schlutz	25.00
Singer vs. Bossingham	166.65
Krueger vs. Bossingham	66.60
Martinson vs. Boeckmann	40.00
Hanson vs. Schlutz	130.00
Johnson vs. Urstad	78.00
Korman vs. Hagen	299.15
Pickar vs. Pierce & McDonald	249.90
Ritter vs. Barber	207.00
Costenoble vs. Tanner	204.25
Korman vs. Hagen	279.02
Johnson vs. Shipley	213.30
Backlund vs. Burch	152.00
Elofson vs. Adkins	153.00
di Berardini vs. Vercellini et al.	127.00
Lorenz vs. Lerche	446.93
Godtland vs. Stewart	207.00
Marka vs. Andrews	399.80
Hawkes vs. Andrews	78.50
Pickar vs. Pierce	78.50
Expenses of Dr. Workman in obtaining evidence concerning Dr. I. S. Benson (not brought into court)	60.60
Total	\$3,739.25

Three of these cases are still pending. Of the actions listed in the attorneys' report three, of the total seventeen, are known to have had private insurance. In each instance this insurance was carried in the Fort Wayne Medical Protective Company. It is optional for members of the Association, in actions instituted against them for malpractice, to avail themselves of the service of the attorneys employed by the State Association regardless of whether or not they have private insurance and thus are entitled to defense through the attorneys of the insuring companies. It is a well deserved compliment to the abilities of the attorneys employed by the State Association that practically all our members ask for defense by the Association attorneys. The Fort Wayne Medical Protective Company sells insurance to our members at a very reasonable rate and for that reason it seems advisable to allow the present situation to continue. Attention is called to the fact that within the last two years, several very substantial verdicts have been obtained against members of the profession. This further emphasizes the desirability of members carrying insurance which covers the payment of damages. While the total fund paid for defense is considerable, when divided equally among the members it amounts to only about \$2.00 per capita.

The details of the work of the Association have been handled in a very businesslike manner in the office of the Executive Secretary, Mr. J. R. Bruce. Full credit should be given especially to Miss Seibert for the very efficient way in which the actual detail secretarial work has been handled.

Six state associations have executive secretaries, who devote their entire time to the affairs of the Associations and their journals. Four of these, however, have a much larger

membership than that of the Minnesota State Medical Association. While there are certain advantages in this method of handling state association affairs, I feel sure that the expense of such an arrangement would be much greater than our present arrangement and not more efficient as regards routine detail work. The full time executive secretary plan would entail a considerable increase in cost of operation and this would have to be met through increased advertising or subscription revenue from the journal to avoid increasing Association dues. I, therefore, strongly recommend that the present arrangement be continued, which provides for a general secretary and an executive secretary.

The demands of my private work and the editorship of the journal make it imperative that I retire as secretary and I, therefore, respectfully offer my resignation, effective at the close of the present calendar year. I wish to express my appreciation of the co-operation which I have received throughout the four years that I have been secretary, on the part of the members of the Association. It is a great satisfaction to be able to state that during the four years which I have served as secretary, the Association membership has increased from about 1,500 to nearly 2,000. This shows a very healthy growth and promises well for the future.

Respectfully submitted,

CARL B. DRAKE,
General Secretary.

(On motion, duly seconded and carried, the Secretary's Report was accepted.)

DR. GEO. D. HEAD: If a motion is in order before we proceed with the next business, it seems to me that it is only the fine thing for us to do to express our appreciation of the services of our Secretary during these last four years. I should like to make a motion that by a rising vote the house show its appreciation of the services of Dr. Drake during the time of his incumbency.

(Rising vote and hearty applause.)

THE CHAIRMAN: Dr. Armstrong, the Report of the Editing and Publishing Committee.

REPORT OF EDITING AND PUBLISHING COMMITTEE

REPORT ON MINNESOTA MEDICINE

Our journal, MINNESOTA MEDICINE, is a publication of which every member of this society may well feel proud. An exceptionally high editorial standard has been maintained for the journal since its inception nearly eight years ago, and it is now generally recognized as one of the best medical journals published. The success which MINNESOTA MEDICINE has had in making a place for itself in medical literature is a source of satisfaction and pride to the Editing and Publishing Committee. The advertising pages have been kept clean and thoroughly in line with the policy of the American Medical Association in this respect. While it must be admitted that this policy affects the volume of advertising, it has been an important factor in maintaining a high standard for the journal.

Since MINNESOTA MEDICINE is your journal, it perhaps will not be out of place at this time to ask that each member of our society evidence a personal interest in it. The personal items department should be enlarged, but this can only be done through the co-operation of the members in sending to the editor items which they think will prove of interest. Members are also urged to give preference to MINNESOTA MEDICINE in replying to advertisements, all things being equal, whenever they are in the market for any of the articles advertised in it. If every member would find it possible to mention MINNESOTA MEDICINE to an advertiser at least once a year, it is believed that this would result in a large increase in advertising revenue. It would show our advertisers, all carefully selected and reliable firms, that our members read the journal and that they are interested in its continued success.

The net surplus for the year is lower than we have reported for several preceding years. One of the causes for this is the increased printing cost and another is a slight increase in fixed charges. The main reason, however, may be charged to the general business depression which has prevailed throughout the country for the past three years and particularly in our own section of the Northwest. With conditions improved, as we have every reason to expect at this time that they will be, an increase in advertising revenue is confidently expected.

Some effort has been made during the year to obtain subscriptions outside the state of Minnesota and we now have, roughly speaking, more than 200 paid subscribers to the journal outside our own state.

About 2,600 copies of MINNESOTA MEDICINE are required each month to cover our mailing list. This includes the society membership, the paid subscriptions of non-members, exchanges, institutions, and other complimentary copies.

J. M. ARMSTRONG, Secretary,
Editing and Publishing Committee.

STATEMENT OF OPERATIONS OF MINNESOTA MEDICINE OCTOBER 10, 1923, TO OCTOBER 4, 1924

REVENUE:

Advertising	\$7,628.10
Subscriptions—Non-Members	342.10

October 4, 1924\$ 602.54

J. M. ARMSTRONG, Secretary,
Editing and Publishing Committee.

(On motion the report was accepted.)

The Secretary read the following report from the attorneys:

REPORT OF THE ATTORNEYS ANNUAL REPORT

October 4th, 1924.

Dr. Carl B. Drake, Secretary,
Minnesota State Medical Association,
Saint Paul, Minnesota.

Dear Doctor:

You have requested it, and we make report to the Association covering the work done by us during the year last past.

Hanson, as Administrator, vs. Schlutz, et al. This action was brought against Dr. F. W. Schlutz and Dr. F. H. Poppe, and the Asbury Hospital to recover damages on account of the death of Lillian Hanson, a child, following an operation for pleural empyema. The case has been dismissed on the merits.

Flynn vs. O'Hara. The charge of malpractice in this case is in producing lacerations with resulting infection in the treatment of Manda Flynn in childbirth. There was a verdict in favor of Manda Flynn in the sum of \$1,600, which verdict, however, on motion for a new trial, was set aside. The action is still pending in Waseca County.

Backlund vs. Frank E. Burch and Charles E. Connor. The alleged malpractice in this case is in severing the tri-facial nerve or its branches, resulting in facial paralysis in

mastoiditis. Backlund has never brought his action on for trial and the case is abandoned.

Godtland vs. Stewart. The alleged malpractice in this case is in advising and permitting the administration of chloroform in the extracting of teeth, the condition of the patient being such that only nitrous acid could be administered, resulting in the death of the patient. Two cases were brought, one covering the death case and the other the loss to the husband, and expenses. The actions have been dismissed.

Martinson vs. Egil Boeckmann et al. The claimed malpractice consists in leaving within the lung cavity gauze and a safety pin, and in failing to remove it, all resulting in the death of the patient. Action has been dismissed as to Dr. Boeckmann but is pending as to the Saint Paul Hospital.

De Berardini vs. Vercellini and Geist. The claimed malpractice consists in improperly performing an abortion, resulting in profuse hemorrhages and general debility. Dr. Vercellini was the family physician and recommended an operation after consultation with Dr. Rothrock. The action has been dismissed.

Korman vs. Hagen. The malpractice claimed in this case is in the premature delivery in childbirth, resulting in a fracture of the femur and Erb's paralysis. There was an adverse verdict in the sum of \$8,000, which is pending on review in the Supreme Court.

Elofson vs. Adkins. The claimed malpractice consists in the improper application of a cast on the leg and in not removing it, causing infection and gangrene, requiring amputation of the leg. The action has been dismissed.

Walrath vs. Hammermeister. The alleged malpractice in this case is in injecting ether into the leg of the patient, thereby causing injury to the sciatic nerve, leaving the patient in a crippled and paralyzed condition. The patient was suffering from pains in the leg. There is also a companion suit brought by the husband. The actions are still pending.

Johnson vs. Shipley. (2 cases.) The malpractice is in introducing into the eye, eyeball and membranes, an acid or foreign substance which severely burned the eyeball and membranes and impaired the sight. Dr. Shipley intended to wash the eye, but in doing so, by mistake used a caustic instead. The case was treated as a liability case, authority was obtained to make settlement, and the cases were settled in the sum of \$750, paid by Dr. Shipley.

Johnson vs. Urstad. The claimed malpractice is the failure of Dr. Urstad to perform an operation to relieve against pleural empyema. The action has been dismissed.

Marka vs. Mankato Clinic. The claimed malpractice is in treating the patient for sciatic rheumatism and in failing to diagnose that the patient suffered from osteomyelitis or arthritis of the left hip joint, resulting in dislocation, shortening and ankylosis. Some of the members of the Mankato Clinic were insured in the Fidelity & Casualty Company and in the Fort Wayne Medical Protective Company, which companies participated in the settlement. Five thousand dollars was paid.

Costenoble vs. Tanner. The claimed malpractice consists in failing to diagnose diphtheria, from which the patient died. The action has been dismissed.

Anderson vs. Ulrich. The claimed malpractice in this case is that the plaintiff did not have surgical resistance; that she was sensitive to poison and in applying Protein sensitization tests, improper dosages were used, resulting in twenty-nine ulcers. The improper dosages, if any, were administered by the interne at the Minneapolis General Hospital. The action is for trial on October 14th.

Singer vs. Bossingham. The alleged malpractice is in failing to remove the afterbirth and in introducing a septic condition, which resulted in focal infection with a crippled condition of the arm. The action was once tried, with a verdict in favor of the defendant. A new trial was ordered by the court for errors in the trial, but the action has now been dismissed.

Ritter vs. Barber. In this case, it is claimed that Dr.

Barber failed to administer antitetanus serum in a cart-ridge explosion on July 4th. The case was dismissed on the merits.

Pickar vs. Pierce. The claimed malpractice in this case was in the negligent failure to perform a Cesarean operation and in failing to make a delivery in childbirth, resulting in the death of the mother. The case was dismissed on the merits. Plaintiff appealed to the Supreme Court, but later abandoned the appeal.

In addition to the foregoing, a number of legal opinions have been rendered to the Association bearing upon various questions. A number of claims of malpractice are pending, but no actions are brought thereon.

Very truly yours,

OPPENHEIMER, PETERSON,
DICKSON & HODGSON,
By Geo. W. Peterson.

(On motion, duly seconded and carried, the report was accepted.)

THE CHAIRMAN: I will call upon Dr. Rothrock for the reading of the Report of the Delegates to the meeting of the American Medical Association.

REPORT OF A. M. A. DELEGATES REPORT OF THE PROCEEDINGS OF THE HOUSE OF DELEGATES OF THE AMERICAN MEDICAL ASSOCIATION AT ITS MEETING HELD IN CHICAGO, JUNE 9-13, 1924

The first meeting of the House of Delegates was called to order by the Speaker, Dr. F. C. Warnshuis, at 10 A. M., June 9, 1924, in the Assembly room of the building of the American Medical Association in Chicago.

After hearing the customary addresses of the Speaker and the President-elect, Dr. William A. Pusey, the House proceeded to hear the reports of officers and Committees.

Report of the Secretary showed that there are now enrolled 90,056 members of the Association, 54,063 of whom are Fellows. It is possible for all members to become Fellows on application.

There are fifty-four constituent State and Territorial Associations, six of which have full time Secretaries.

The House of Delegates for the first time met in the Assembly room of the new A. M. A. building, which now houses all the various activities of the Association.

The subscription to the Journal has now reached 80,958, and from its size and contents has now reached a leading position among medical publications. The new popular magazine, "Hygeia," has reached a total circulation of 23,687 and in Chicago the contents have been used for radio broadcasting with the announcement that the material comes from Hygeia, through the American Medical Association.

From Report of Judicial Council: Periodic Health Examination by Lay Organizations.

Following the commitment of the Association at its San Francisco Session to the principle of encouraging periodic medical examinations for those who apply and even preceding this it has come to the notice of the Judicial Council that numerous commercial organizations have been formed who employ recent graduates or hard pressed practitioners to make these examinations at very low per capita rates, ranging from \$2.00 to \$5.00, and then sell this service to the individual for prices ranging from \$10.00 to \$25.00.

It was disclosed that some members of the Association, some even high in its councils, had unthinkingly lent their names as references, not understanding the use that was to be made of them. It was disclosed that some of these Companies are stock companies, one of which was reported to have an authorized capital stock of \$400,000 and one Company claimed to have 8,000 doctors listed as examiners.

It is the judgment of the Judicial Council that if such examinations are to be made they should be made independently by the physician, the examination should be thorough and should be charged for accordingly at customary rates.

ABSTRACT OF THE COUNCIL'S REPORT

MEDICAL EDUCATION

1. Although the total number of medical schools has been reduced from 160 to 80, the number of high grade, better equipped colleges has been increased from 2 to 74.

2. The total number of medical students was reduced from 28,142 in 1904 to 12,930 in 1919, but since 1919 the enrollments have been increased by nearly 1,000 students each year, the total number of students at present enrolled being approximately 17,808—the largest number since 1912.

3. The number of graduates of medical schools, likewise, was reduced from 5,747 in 1904 to 2,670 in 1918, but since 1918 there has been a rapid increase interrupted only by the war class which graduated in 1922. An estimate indicates that in 1927 there will be 4,750 graduates, the largest number since 1908.

4. The higher entrance requirements and the other improvements made in medical education, therefore, are not causing a dearth in the numbers of either medical students or graduates. As a result of the changes, however, there has been a positive increase in the number of graduates who are better qualified, both educationally and professionally, from 267 or 5 per cent of all graduates in 1906 to 2,964 or 95 per cent of all graduates in 1923.

5. Although the number of medical schools is only one-half of what it was in 1904, the capacity has been greatly increased. Instead of only 156 students and only 36 graduates for each college on the average in 1904, now each college on the average has 223 students and in 1927 will turn out about 60 graduates.

PHYSICIANS TO POPULATION

6. The United States now has one physician for every 724 people as compared with one to 1,087 people in the British Islands and one to about 2,000 people in the countries of Central Europe.

7. Although the number of physicians in rural districts is smaller, this does not mean in all instances a decreased medical service, since the better means of rapid transit enable one physician to take care of a larger area than heretofore. The scarcity of physicians in rural communities is more than offset by a great oversupply in the cities.

RESOLUTION ON THE NATIONAL PROHIBITION ACT

This question comes before the House of Delegates each year but we have been able to accomplish nothing in the past.

According to present ruling a physician is permitted by law to prescribe only one pint of whiskey at intervals of ten days for the same patient. This ruling was the result of abuse of their privilege by certain unscrupulous members of the profession. Now it is contended that one pint in ten days is an infringement upon the rights of the physician in attempting to dictate the amount and dosage of a useful drug. The following resolution was passed:

Resolved: That the House of Delegates of the American Medical Association expresses its disapproval of those portions of the National Prohibition Acts which interfere with the proper relation between the physician and his patient in prescribing alcohol medicinally; be it further

Resolved: That the House of Delegates of the American Medical Association instruct the Board of Trustees to use its best endeavor to have repealed such sections of the National Prohibition Acts as are in conflict with the above resolution and also use their best endeavor to have the Commissioner of Internal Revenue and the Prohibition Commissioner issue revised instruction on the use of the prescribing of alcoholic liquors for medicinal purposes by physicians.

The election of officers resulted as follows:

President—Dr. William D. Haggard, Tennessee.

Vice President—Dr. E. B. McDaniel, Oregon.

Secretary—Dr. Olin B. West, Chicago.

Treasurer—Dr. Austin A. Hayden, Chicago.

Speaker of House of Delegates—Dr. F. C. Warnshuis, Michigan.

Vice Speaker of House of Delegates—Dr. Rock Slyster, Wisconsin.

Vacancies on Board of Trustees were filled as follows:

Dr. J. H. Walsh was elected to succeed Dr. Frank Billings.

Dr. E. B. Heckel was elected to succeed Dr. Wendell Phillips.

Dr. Thomas McDavitt was elected to succeed himself.

Dr. George H. Simmons, who for the past 25 years has been Editor of the Journal and General Manager, and under whose supervision the Association has reached its high state of organization and has been brought to its present point of efficiency, has tendered his resignation and it was voted that he be made Editor and General Manager Emeritus at a salary of \$5,000 a year.

When Dr. Simmons retires Dr. Olin B. West will become Acting General Manager and Dr. Morris Fishbein, Acting Editor of the Journal, and Will C. Braun, Acting Business Manager. All to serve until the next annual meeting of the Board of Trustees the first Friday of February, 1925.

This being the year for reapportionment, the representation of the various states in the House of Delegates will in the future be on the basis of one delegate for every 950 members or fraction.

According to the reapportionment Minnesota thereby gains an additional delegate and will be represented in the future by three instead of two delegates.

Atlantic City was chosen as the next place of meeting, subject to the action of the Board of Trustees.

J. C. LITZENBERG,
J. L. ROTHROCK.

(Motion to accept the report duly seconded and carried.)

THE CHAIRMAN: Report of Committee on Public Policy and Legislation, Dr. Christison.

REPORT OF COMMITTEE ON PUBLIC POLICY AND LEGISLATION

September 10, 1924.

To the President and Members of the House of Delegates of the Minnesota State Medical Association.

Gentlemen:

Owing to the fact that the Legislature of the State of Minnesota was not in session during 1924 the activities of your Committee on Public Policy and Legislation have been necessarily limited. We have co-operated with your Committee on Public Health and heartily endorse the recommendations made in their report.

During the sessions of the Legislature of the State of New York we received almost daily bulletins covering the activities of the Committee on Legislation of the Medical Society of the State of New York.

It would seem from these reports that this Society maintains an office at Albany and has a full time man covering the legislature during the entire session. Whether this is feasible in Minnesota or not your Committee does not know but the subject is worthy of consideration. Telegrams were sent to Governor Smith and Senate Majority Leader James M. Walker at Albany, at the request of Dr. James M. Vanderveer, the Chairman of the Legislative Committee of the New York Society, in the name of this Association, urging the passage of bills relating to the practice of the cults.

A request was received from Dr. W. C. Woodward, Executive Secretary of the Bureau of Legal Medicine and Legislation, of the American Medical Association, requesting a transcript of the evidence in a suit brought to test the constitutionality of the Chiropractic law in Minnesota. Interviews with Judge H. D. Dickinson, of Minneapolis, before whom the case was heard, and with Attorney General Hilton, disclosed the fact that there was nothing of value in the evidence and Dr. Woodward was so informed.

At Dr. Woodward's suggestion letters were sent to the Senators from Minnesota and to each of the members of the finance committee of the Senate, urging modification of the Harrison Narcotic Act, Reduction of the Tax Rate on

Earned Income, and favoring the deduction of physicians' expenses incurred in post-graduate study and in attendance at medical meetings, in the computation of Income Tax.

Letters have been mailed to the chairmen of the Legislative Committees of all County Societies, or to the Presidents or Secretaries of these component Societies, urging them to get in touch with the various aspirants for legislative honors and urge upon them the advisability of informing themselves on medical legislation and to point out to them before they are elected, the necessity for proper regulation of the practice of medicine and surgery.

It is recommended—first, that if possible a full time man be employed during the legislative session, and second, that if any definite legislation is desired by this Association it be formulated at this session and put before the prospective candidates.

J. T. CHRISTISON,
J. G. CHASE,
CHAS. B. WRIGHT,

Committee on Public Policy and Legislation.

DR. J. T. CHRISTISON: Since that report was written we have received a communication from Dr. W. C. Woodward, the executive secretary of the Bureau of Legal Medicine of the A. M. A., asking us to endorse several items. First of all,—I am not going to read all of this, just simply the headings—the regulation of the sale of lye and other caustic substances. Second, the amendment to the National Prohibition Act, removing present legislation which, it is pointed out, interferes with the relations of physician to patient. Third, the Harrison narcotic tax. Fourth, regarding cosmetics, hair dyes, etc. Fifth, regarding the organization of federal health activity. Sixth, exemption of traveling expenses to and from medical meetings from inclusion in the income tax. We also have here a copy of the resolution which Dr. Rothrock read to you. Dr. Woodward asks in his letter that this society go on record as favoring the passage of these bills.

(A motion was duly seconded and carried that the report be accepted, adopted and published at the earliest possible convenience.)

THE CHAIRMAN: Dr. Baker, the Report of the Committee on Sectional Work.

REPORT OF COMMITTEE ON SECTIONAL WORK

For some years our State Medical Meetings have had two sections—Medical and Surgical. Your committee, after careful consideration of the advisability of changing this plan, has come to the following conclusion:

While we do not deny the importance of any special field of medicine, there is no general demand and we do not feel that any subject merits a special section. Instead of creating more sections, we wish to bring to your earnest consideration the advisability of returning to our old custom of having one general meeting. It is well for the surgeon to listen to the medical man, the general practitioner to the specialist and vice versa.

We believe that a State Association should not be a place for specialization. For those seeking this, there are other and better avenues. We believe that our state meetings should consider the common good of all the people as well as all the practitioners of this state and that we should consider these problems together.

We believe that a properly functioning program committee will see to it that each subdivision of medicine will receive the attention which it deserves. If we do this each may know, hear and partake in all that transpires and he will return home with a more charitable and sympathetic view of his brother practitioners and with a broader understanding of the problems of the medical profession.

Our numbers are not too large for successfully carrying

out this plan for they are rarely as large as most of the sectional meetings of the A. M. A.

An example of a great success, in a one section meeting, is the Tri-State Medical Association. This holds yearly a four-day session covering the entire field of medicine and surgery. The attendance at these meetings has been as high as fifteen hundred.

A. C. BAKER,
W. F. BRAASCH,
V. C. HUNT.

A MEMBER: I move we accept the report.

DR. W. A. JONES: I wonder if the time is not approaching when most state associations will do a little better than they have done before in mixing clinics with their papers. It seems to me that the Tri-State Society Dr. Baker has referred to has accomplished wonders in this direction, and I believe that we could make our state association a much more valuable aid if we incorporated as we did at Duluth a few papers and many clinics. I believe the men would get more out of it and it would be a much more interesting and satisfactory meeting. I wish this matter might be taken up for consideration.

DR. GEO. D. HEAD: It strikes me that possibly before taking rather hasty action upon this recommendation of the Committee without due consideration it might be well for us to know exactly the situation from the preceding chairmen of the sections as we are at present organized. It has always seemed to me that we ought to encourage as much as possible the presentation of the work of the various members of our association at our state meeting, and especially to encourage young men in any research or clinical work that they may wish to present. Now if we adopt the one session idea and go back to our old plan, I for one feel that it has many strong points, this meeting together in one general session. Nevertheless, with our large association and our growing membership, isn't it going to cut off the opportunity for many of the younger men in the profession to be encouraged to come in here and present their work? I would not like, for one, to vote for a method of organizing our program which would have a depressing effect upon the younger man in the profession. It seems to me that it is very important for us to know whether or not the chairman of the surgical section has had more papers offered on his program this year than he could well accommodate in the program, and the same of the medical section.

I would like to make an amendment to Dr. Jones' motion therefore, that the Chair appoint a special committee to take up the report of the Committee on Sectional Work and report at the last meeting of the House of Delegates. Perhaps Dr. Jones would be willing that that amendment should be accepted; that a special committee be appointed by the Chairman to investigate this side of the matter before we finally vote.

DR. W. F. BRAASCH: Before voting further on the question, Mr. Chairman, may I simply say that it is the intention of this Committee not to shorten the number of papers and to abbreviate the program at all. It is scarcely within our province to detail the programs, that is, to set the program to the extent that we had planned. However, we wanted to incorporate the idea of Dr. Jones. Now in adopting this method instead of shortening the program we would lengthen it. In other words, the point of our idea

was to have clinical presentations, case reports, slides and illustrations, pathological demonstrations, things of that type, limited possibly to eight or ten minutes, much the same as they do in the Tri-State Assembly. Now you take for instance a one-day program of the Tri-State Assembly embodies a good deal more than our entire program does in the two sections this year. Instead of curtailing the opportunity it would increase the opportunity for the presentation of the subject by adopting that method. We did not think it was our province to go into that in detail, but that was our intention.

(The motion to accept the report, without adoption, was duly carried.)

DR. V. C. HUNT: I think in answer to the question that Dr. Head raised, the atmosphere can be cleared in just a few moments. Regarding the difficulties concerning getting papers, Dr. Tuohy I am sure in a very few minutes can give his report of the work in getting the Medical Section rounded up.

DR. E. L. TUOHY: I had no difficulty in getting papers for the Medical Section, and I think the Surgical Section had the same experience. Many papers were offered. The question may be answered directly as outlined by Dr. Braasch, but another feature involved has to do with the ultimate welfare and standing of our state journal. If too many of the papers or discussions are in the form of clinics, a valuable source of material for the publication of the journal is lost, and while a considerable number of papers may always be available for publication, it is just possible that they might not represent the state as a whole as well as if it were possible to draw some of this material from these meetings. I would feel, therefore, that it would be advantageous to study the matter out closely. The giving of a program, however, in which clinical demonstrations bear a part must certainly be a work of the future, because it has been shown repeatedly already that that type of meeting will draw more attention and better results than papers alone.

DR. W. A. JONES: I make the motion that a change in the by-laws be made providing for the return to the one section, to be voted on at the meeting tomorrow according to the constitution. I also request that the officers or the Executive Committee order the by-laws so that they may conform to the different sort of meeting. I would like to say that it has been my experience, and I think Dr. Tuohy will agree, that the clinical reports are much better and much more frequently read than these massy papers, and I think it would increase the popularity of the journal rather than to decrease it.

THE CHAIRMAN: I would like to know what Dr. Drake thinks about that. Do you think that the clinical meetings bring out the material in such form as to be available for publication?

THE SECRETARY: I do not know that I can answer that question inasmuch as in MINNESOTA MEDICINE we have published very few case reports. The reports of the proceedings of the Minnesota Academy and the Minneapolis Surgical Society are about the only case reports that we publish. We haven't had more than perhaps half a dozen additional case reports in the last year. I think probably the members of the House of Delegates know pretty well

what they read. I feel this way about it, that we get a good many case reports in the meetings of the hospitals nowadays. I do not think there is any more valuable way of getting information than by reading such reports. The formal paper is a very valuable part of a state medical publication, but I think that possibly the papers that are presented could be given in an abstract form at the meetings, and we could get in therefore a greater number of papers. If we have a combined section as proposed, we will have to cut the presentation time down in order to get the same number of papers in that we have in the two sections now.

If this matter is allowed to go in the form of a motion that a special committee present it tomorrow, we will have to wait a year. If it is the wish of the House of Delegates to have a common meeting throughout the convention next year, the motion should embody that at this time; that is, have the proposition before the House at this time to be acted on tomorrow. Dr. Jones' motion ought to embody that, and I do not think it did. Will you ask Dr. Jones to repeat?

DR. W. A. JONES: I would like to move that Dr. Baker's recommendation for the single meeting be adopted at the next meeting of the House of Delegates, and that the Program Committee be instructed to put on any kind of program they may see fit, but to embody the clinical material for the presentation to the association as much as possible. I think that is really the substance of the motion that I intended. My intent is to get the association to combine both papers and clinics, hoping that clinics will predominate.

DR. W. A. COVENTRY: May I ask for the reading of the by-laws to cover that subject?

THE SECRETARY: Under Chapter VIII of the By-Laws there is a provision made in Section 1 for (reads) "A Committee on Scientific Work, consisting of two sections." In Section 2: "For medical advancement and scientific work the Association shall be divided into two sections to be designated, 1st, Section on Medicine, 2nd, Section on Surgery, under which shall be grouped the appropriate subdivisions represented by the special branches of Medicine and Surgery respectively." Under Chapter XII—Amendments: "These By-Laws may be amended at any annual session by a majority vote of all the delegates present at that session, after the amendment has lain on the table for one day."

DR. W. A. COVENTRY: May I ask for a point of information? If I understand Dr. Jones, my idea is that you do not amend the by-laws but offer a recommendation for the committee next year. If you are going to amend the by-laws it has to be introduced today and acted on tomorrow. If you are not going to do that, it means that there will be two chairmen and two secretaries for the two sections, and under Dr. Jones' recommendation it will be possible to combine these, that is, the secretaries and the chairmen of the two sections get together and arrange a program as they wish. If you have only two sections for one part of the day, that is enough to cover the point without necessarily amending the by-laws. If you amend the by-laws you may want to re-amend them again next year, and you will get a lot of confusion before you get through with it.

DR. J. L. ROTHROCK: Inasmuch as I was the one who started the establishment of this sectional arrangement, I

would like to state to the delegates the reason why that was done. It was found that previous to that we sometimes met in the smaller towns where there was not an adequate hall to accommodate all those who wished to attend the sessions. The places of the meetings were small. It was also believed that we might be doing just twice the amount of work by having two sections. An arrangement at that time was made and intended that a certain number of these sessions should be together, that is, combined sections, and a portion of the time spent in that way. At those times symposiums on various subjects would be discussed. In the larger cities of course there are usually halls adequate for housing all of the association, but sometimes the halls that we were meeting in were crowded and it seemed to a number of us who thought of this plan that it would be a good plan and that we might just double the amount of work we were doing. We seemed to be doing a very creditable amount of work for a large association like a state association. That was why this change was made. Previously, I might say, the getting up of the program was left to the secretary of the association, and we thought that we would get better programs if we had a chairman for them, and the chairman and secretary get up the program.

I cannot see now why it would not be a good idea to continue on this plan but make some arrangement for combined sessions. That will cover the demand which seems to be present today. As far as Dr. Braasch's statement is concerned, that one session could cover the same amount of ground as both, I can't quite see how that is possible in a limited time. Unless the days of the meeting were extended, I can't see how it would work out.

DR. GEO. D. HEAD: The reason why I made the amendment to Dr. Jones' motion which I did was because it seemed to me that this was a radical change from the method that we have been following for some years, and it struck me that by making a little bit of a change in the method by which the chairmen of the different sections presented their material we could accomplish with our two section arrangement almost all that we could by having a one section program, and besides we could obviate some difficulty. Now there is no question at all but what in this state gradually but surely we are developing men who are interested in and practice the medical side and men who practice and develop to a greater degree year after year the surgical side. While it is of course advantageous for those men to get together in common conference over certain classes of disease, those conferences can all be well arranged by having a combined program such as we have tomorrow in our general session. That can be enlarged and more programs of the two sections put together if necessary. I do not believe it is conducive to the best work in medicine for men interested more in the medical side of practice, medical, diagnostic, and consulting work, to be compelled to listen to programs in which the surgical considerations predominate, and vice versa.

Now can't we proceed with our same arrangement of two sections and still provide all that Dr. Braasch has suggested? Could not this year a common program where the two sections meet together be devoted entirely to the clinical presentation of cases, instead of having it that each section

have presented such papers as are of interest either to the surgical or the medical section. Let those papers be presented to men interested; then let us all come together in these common sessions and have those clinical sessions and have no papers at all but have many short presentations, a very well boiled down, concentrated program upon the clinical side of medicine, presenting practical cases. It seems to me that it would be very radical for us to change our plan of working without more due consideration.

I therefore wish to make an amendment to Dr. Jones' motion, that the recommendation of the Committee be referred back again to this same Committee, the Committee on Sectional Work, for another year's consideration.

DR. W. H. WORKMAN: I do not see any reason for discussing this thing at all. It is already provided for in the by-laws. Article VIII—Sessions and Meetings, Section 1 provides (reads): "The Association shall hold an Annual Session, during which there shall be held daily General Meetings, which shall be open to all registered members and guests." We do not have to change our constitution or by-laws or anything else; we can have the clinical meetings under our present regulations. We already have one general session in an afternoon; that can be made a whole day. I do not see anything to change at all.

DR. W. F. BRAASCH: I disagree with Dr. Head in the statement that this is a radical change. I wonder if he has ever attended a meeting of the Tri-State Assembly and if he has seen the enthusiasm and the general approbation with which those programs are received. Everybody enjoys them; everybody can get what he wishes. Dr. Baker says in his report that it does a surgical man good to hear a discussion on medical subjects and it does a medical man good to hear a discussion on surgical subjects; in other words, most of us here are general practitioners, and I think it would do them good to hear both sides. It appears to me that this method is very elastic and offers large opportunities in the form that is to be pursued. This method is not radical either, because it has been adopted by several state associations.

DR. GEO. D. HEAD: I didn't mean it was radical—I knew that programs have been arranged along this line; but I meant it was a radical change for our own association.

DR. J. G. CROSS: Is Dr. Head's amendment seconded?

THE CHAIRMAN: I think not.

DR. J. G. CROSS: I would like to second his amendment, and in doing so may I ask that the report as read by Dr. Baker be reread as far as it relates to the desired single sections?

(At the request of Dr. Drake, Dr. Baker read the following:)

DR. A. C. BAKER: "While we do not deny the importance of any special field of medicine, nevertheless there is no general demand and we do not feel that any subject merits a special section. Instead of creating more sections, we wish to bring to your earnest consideration the advisability of returning to our old custom of having one general meeting. It is well for the surgeon to listen to the medical man, the general practitioner to the specialist and vice versa."

DR. J. G. CROSS: You simply bring to the attention of the society the desirability of these single meetings.

DR. COVENTRY: Question.

THE CHAIRMAN: You have heard the motion as made by Dr. Jones and I think seconded by Dr. Braasch with reference to presenting this matter to the House of Delegates tomorrow. As many of you as are in favor signify by saying aye. Contrary, no. Carried.

And the amendment of Dr. Head, that the matter be referred back and reported on one year from now. Is that the amendment, Dr. Head?

DR. GEO. D. HEAD: To the same committee for one year.

DR. W. A. JONES: I cannot refrain from talking about this more. It seems to me that this is unnecessary to wait a year to try out some wholesome experiment. We can put a medical and clinical section over at one session just as well as not, if we will do it. I should like to introduce another resolution while I get a chance, authorizing and directing the Program Committee to follow this out. I hope Dr. Head's amendment will not prevail.

DR. J. C. LITZENBERG: I rise to a point of order. The original motion has been acted upon, and that disposes of all amendments.

DR. J. W. BELL: I think the Chair perhaps erred slightly. The amendment should have been considered first, and I think it might be well for us to go back and take it up.

THE CHAIRMAN: I stand corrected.

DR. J. C. LITZENBERG: I rise again to a point of order. The motion to reconsider must be passed before we can go any further.

DR. GEO. EARL: Can we not secure what we are all striving to get by having Dr. Head now make a motion that the Chair appoint a committee to report to us on Dr. Jones' motion tomorrow? That will serve the purpose and we will vote on this question tomorrow, and we will also have the advantage of Dr. Head's committee.

DR. G. S. WATTAM: I would like to ask this question: Could not Dr. Jones' motion be amended tomorrow if it is felt necessary?

THE CHAIRMAN: I understand that tomorrow it has to be settled. I am going to ask Dr. Head if he will make a motion to get me out of hot water.

DR. GEO. D. HEAD: I will be very glad to do that. I move you that the Chair be authorized to appoint a special committee to make a special report upon this matter at our session tomorrow.

(Motion seconded and carried).

THE CHAIRMAN: I will appoint on that committee Dr. Braasch, Dr. Head and Dr. Jones.

The Report of the Committee on Cancer, Dr. Hunt.

REPORT OF COMMITTEE ON CANCER

To the President and House of Delegates of the Minnesota State Medical Society: Your Cancer Committee begs to submit the report of its activities during the past year.

A review of the discussion precipitated by the report of this Committee at the meeting of the House of Delegates on the first day of the State Society meeting in 1923 presents an interest in the subject of cancer control manifested for the first time. This discussion in itself has served as a stimulus to all members of the Committee to continue in behalf of the State Medical Society the conduct of the educational work as outlined and directed by the American Society for the Control of Cancer.

The constructive criticism offered after the presentation

of the 1923 report has resulted in the coalition of the Cancer Committee of the State Medical Society and the State Cancer Committee of the American Society for the Control of Cancer, which enables the Committee to carry on the activities of cancer control under the direction of the State Medical Society. As a result, the activities of this Committee have been conducted in the past year with increasing harmony in the membership of the State Medical Society. As stated in previous reports, it has been the opinion of the State Cancer Committee that it could best serve the interests of the State Medical Society by co-operating with the American Society for the Control of Cancer in its educational campaigns.

The campaign, as outlined in previous years, was again conducted in Minnesota throughout the week of November 11th to 18th in 1923. During that week statewide publicity was given the most salient facts about cancer, through the organization and activities of seventy-six County Cancer Committees. Through these organizations short talks were given, and literature, furnished by the National Society, was read before many audiences, including churches, fraternal organizations, clubs, et cetera. Thirty-one public meetings were held under the auspices of County and District Medical Societies. The newspapers throughout the state contributed liberally of space for articles dealing with the known facts about cancer, furnished by the National Society. Other activities consisted of five cancer clinics, two radio talks, the showing of the film, "The Reward of Courage," and slides in many theatres, et cetera.

Your Committee believes that educational work should continue and desires the co-operation of the individual members of the State Medical Society. Also, the Committee wishes to follow the suggestion of the House of Delegates in the conduct of its work.

We desire at this time to express our thanks and appreciation to the members of the State Medical Society who have been active in the educational campaigns, particularly those who have acted as County Chairmen, and those who have contributed their time and money in the presentation of public lectures.

Respectfully submitted,

VERNE C. HUNT, Chairman,
A. C. STRACHAUER,
AARON F. SCHMITT,
HENRY WIREMAN COOK,
HARRY P. RITCHIE,
A. J. CHESLEY.

(Motion to accept the report duly seconded and carried.)

Dr. C. B. Lewis called attention to the entertainment planned for the ladies for Thursday: Tour of the State Reformatory, luncheon and band concert there, and visit to Watab Pulp and Paper Company's plant.

THE CHAIRMAN: Report of the Necrologists, Dr. McDavitt.

REPORT OF NECROLOGIST

We are again called on to chronicle the names of those who have laid down their burdens and gone to that bourne from whence there is no recall. All of these honored names have performed their allotted tasks with honor and credit to themselves and their communities and well deserve the encomium, "Well done good and faithful servant." Those of us who remain can only honor their memory by emulating their virtues. As indicating the uncertainty of this life the necrologist of last year, Dr. J. H. Adair, heads this list of our departed members. It is with high regard and admiration for lives nobly spent that we detail the list of our confreres "who have finished the course" and have gone to their reward.

FORMER PRESIDENTS

NAME	ADDRESS	YEAR	DECEASED
Adair, J. H.	Owatonna	1920	1/ 6/24

(On motion the report was accepted.)

THE CHAIRMAN: Next is the Report of the Committee on Hospitals and Medical Education, Dr. J. C. Litzenberg.

REPORT OF COMMITTEE ON HOSPITALS AND MEDICAL EDUCATION

To the President and House of Delegates of the Minnesota State Medical Society:

Gentlemen: Your Committee on Medical Education and Hospitals has the honor of submitting the following report: FIRST—HOSPITALS:

In its work of raising the standards of hospitals the Council on Medical Education and Hospitals of the American Medical Association has adopted the plan of publishing a list of hospitals approved by it for the training of interns.

In addition to an investigation of each hospital by a representative of the Council from the home office at Chicago the Committee on Medical Education and Hospitals of the state in which any hospital applying for approval is located is asked to make an independent investigation and report to the Council. Your Committee was requested to make one such survey during the year, namely, of the New Asbury Hospital of Minneapolis. The survey was made and the hospital recommended for approval by the Council. Seventeen hospitals in Minnesota are now approved for the training of interns.

SECOND—MEDICAL EDUCATION:

The Committee on Medical Education and Hospitals of last year, headed by Dr. Braasch, made a very comprehen-

sive and valuable report on both undergraduate and graduate medical education in Minnesota.

Your present Committee will therefore not go into any detail concerning the present status of medical education in the state, but will first take up the recommendations of Dr. Braasch's Committee to see whether or not the profession of the state has profited by those wise proposals. Too often recommendations of Committees which have spent valuable time and concentrated effort on their work are literally thrown into the waste basket by the hackneyed motion, "I move the report of the Committee be accepted and placed on file." Therefore, your present Committee makes but one recommendation with the hope that the Committee next year will be instructed to concentrate all its efforts on education to be carried to the physician in his own locality.

The recommendation of Dr. Braasch's committee—

"That the University of Minnesota offer several courses of instruction at different periods of the year and possibly in a more concentrated form" has been carried out by the University.

In the spring, for two weeks, courses were offered "in a more concentrated form" in Medicine and Surgery, and in the fall for another two weeks in Pediatrics and Obstetrics and Gynecology, together with a one week's course in x-ray diagnosis, laboratory clinical and pathological diagnostic methods.

Another recommendation of last year's Committee was:

"That a system of graduate medical instruction be given by competent instructors in various portions of the state enabling the general practitioner to become familiar with recent medical progress." This has been taken up by your present Committee which begs leave to make the following report of its investigations with recommendations for putting it into effect: Certain states, notably Wisconsin and North Carolina have undertaken to take instruction to the practitioner. Time and space will not permit a detailed description of this work but the essential features of the plan are these:

Wisconsin. "The purpose of the courses offered in post-graduate medical instruction is to provide physicians, residing in a given locality, with practical demonstrations of the newer methods of diagnosing and treating disease. Clinics are held at a hospital conveniently located, illustrated lectures are given, and opportunity is offered for consultations with specialists. Arrangements may be made for a single clinic and lecture or for a series of weekly, bi-weekly, or monthly clinics and lectures. Arrangements for these clinics and lectures are made through co-operation between the local physicians under whose auspices the clinics and lectures are held and the Dean of the University Extension Division. Physicians enrolling for the course are charged a fee sufficient to cover part of the overhead expenses, the balance is paid from the small appropriation made for this work by the state legislature. The following courses, each consisting of one clinic and one lecture, are offered:

Internal medicine, radiology, pediatrics, dermatology and syphilis, neurology and psychiatry, genito-urinary diseases, orthopedics, laboratory diagnosis; diseases of the eye, ear, nose and throat; obstetrics and gynecology.

The courses are given by teachers from the University of Wisconsin and prominent professional men of the state.

In addition to these courses obstetrical films are exhibited and the cancer propaganda is conducted in harmony with the above courses by a committee of the State Medical Society of Wisconsin, illustrated by 125 slides.

North Carolina. In this state the work is also conducted by the University Extension Division.

Mr. Chester D. Snell, Director of the Extension Work, in a letter to Mr. R. R. Price, Director of the same work at the University of Minnesota, says:

"I should like to make it clear that the work which we are offering is regular post-graduate medical instruction, and is not devoted to clinics alone. Each class meeting last summer lasted about three hours, of which an hour and a half, approximately, was devoted to a lecture by the in-

structor and the rest of the time was taken up by clinical work. Some of the meetings lasted a whole afternoon when the classes got interested in the clinical work.

"We ran two circuits of six towns each last summer, and the total attendance in each circuit was one hundred each, or an average of seventeen in each group or class. This next summer we expect to run at least six circuits, and hope to have practically all the general practitioners in this state taking the work.

"Let me say that as far as we are able to judge, this work has been a tremendous success in this state, and we believe we have found a solution of the problem of how to give busy doctors post-graduate medical instruction without great expense or loss of time to them."

"The plan is briefly this: The University Extension Division, in co-operation with the Dean of the Medical School, serve in an organizing capacity. The best available instructor in the country is secured to give the course. Between ten and twenty physicians are assembled at five or six conveniently located towns accessible to the instructor on one day each week for twelve weeks. Each meeting consists of a one-hour lecture and from one to two hours of clinical work. Each group therefore receives a total of twelve lectures and twelve clinical demonstrations. The cost to each person is guaranteed to be not more than thirty dollars. Should the total receipts exceed the cost, the excess will be refunded pro rata.

"Post-graduate medical education is a necessity because of the rapid advancement in medical science. The average general practitioner cannot afford to be absent from his practice six weeks in order to take a course in residence at a cost of \$400 or \$500. What is now known as the 'North Carolina Plan' was inaugurated in the summer of 1916.

"Two instructors were appointed. Each was assigned to a circuit of six centers, which he covered in rotation every week for four months, a class thus being held in each city once a week. The classes were composed of physicians residing in these centers and their surrounding rural communities.

"The actual organization of the classes, and the planning of the instructors' routes and other executive work was carried out by the University Extension Division, while the more strictly medical problems, notably the selection of the instructors and the outline of the work, were in the hands of the Dean of the Medical School."

The experiment in these two and other states has been very successful. Your Committee believes that the profession of this state will welcome an opportunity to broaden its knowledge and to keep up with medical progress which some such plan will furnish at a minimum expenditure of time and at a reasonable cost.

Therefore your Committee recommends:

1. That the Committee on Medical Education and Hospitals be instructed to confer with Mr. Richard R. Price, Director of the Extension Division, and Dean Lyon, of the Medical School, as to the feasibility of the scheme. (Mr. Price and Dean Lyon have expressed to the Committee their willingness to co-operate with the State Medical Society in every possible way.)

2. If found to be practicable, to adopt a plan suitable to the peculiar conditions in Minnesota, and

3. Subject to the approval of the Council to put the plan into effect in co-operation with the Director of the Extension Division and the Dean of the Medical School of the University of Minnesota.

4. Finally your Committee believes that the plan can be made self-supporting but it realizes that in inaugurating any new scheme there may be some incidental expenses necessary; we therefore recommend that a small appropriation be made to insure success.

Respectfully submitted,

J. C. LITZENBERG, Chairman,
A. R. COLVIN,
E. S. JUDD.

DR. H. P. DREDGE: I move the adoption of the report—I do not say acceptance; I say adoption. And I would like

to ask what appropriation this Committee thinks would be advisable.

DR. J. C. LITZENBERG: Well, I do not know, but the only expense would be office expense, stenographic expense, a little printing, and things of that sort. I do not know what it would cost. Fifty to one hundred dollars probably would be the outside figure. As far as that is concerned, there would be reimbursement afterwards. Mr. Price, of the Extension Division, has expressed his willingness to do the executive work on this, and he is very enthusiastic about having the State Medical Society conduct this work through its own committee rather than to have it conducted simply by the University. He thinks that that is the way to conduct it because then it will be the State Society's own scheme, but he is willing to offer his services. I asked him if there was any available money in his appropriation, and he said no. Therefore we have made this last recommendation. I think a motion not to exceed one hundred dollars would probably cover it.

DR. R. T. EDWARDS: I would move, Mr. Chairman, that this report be adopted and that we make an appropriation of such money as is necessary, not to exceed one hundred dollars, for the work, subject to the approval of the Council.

(Motion duly seconded and carried.)

THE CHAIRMAN: Committee on Public Health, Dr. Savage.

REPORT OF COMMITTEE ON PUBLIC HEALTH

In response to a letter from the chairman of the State-wide Publicity Committee your committee on April 15, 1924, met with Dean Nicholson and the director of the University Public Health Service and the Vice-president of the Hennepin County Medical Society to investigate the Public Health Service of the University of Minnesota.

The following statements were made by representatives of the Public Health Service. About 60 per cent of the University students are putting themselves through college either in whole or in part. Ninety per cent of those who report to the staff would probably not see any physician if it were not for the public health service.

The public health service refers a great many students together with their findings to their family physicians when they live in the Twin Cities, and their policy is to do this in those cases where they feel they are able to pay ordinary fees. They admit that the occasional case able to pay ordinary fees occasionally slips by them, but of what free institution is this not true?

In the judgment of your committee the great work they are doing is that of educating these young people to the value of regular examinations, to the value of reporting themselves early in case of sickness and last but not least the thousands of students are graduated educated to the value of regular medicine rather than being advocates of the cults.

As to the good accomplished among the student body there is no question. This is detailed in the April issue this year of MINNESOTA MEDICINE.

Your committee wishes to go on record as heartily indorsing the University Public Health Service.

For the first time the State Medical Association in conjunction with the University of Minnesota has put on a health exhibit at the State Fair. Dr. Wm. O'Brien, of the Medical Department, has had charge of the work and the medical association has paid the bills. The general scheme was outlined in the September issue of MINNESOTA MEDICINE.

At the 1923 session of the House of Delegates the Committee on Public Health for this year was requested to gather information throughout the United States relative

to the points of contact between the medical profession and the public. Forty-nine questionnaires were sent and thirty-three responded. Including Minnesota we have statistics from thirty-four states.

No. 1. Does legislation initiated by the medical profession meet with a fair degree of co-operation in your state or the reverse?

Excellent 6%, good 14%, fair 40%, poor 40%.

No. 2. Are the medical men of your state organized into legislative committees with reference to proposed legislation?

In nine states special organizations; in 24 states handled by the state committee; in one state no organization.

No. 3. Does your State Association or public health agency publish a journal devoted to medical and public health matters for the laity?

Six states do this including Minnesota and one state has a tuberculosis journal.

No. 4. Does your State Association or any component medical society approve or conduct systematic radio talks?

Kentucky, Ohio, Washington (state), Pennsylvania and Wisconsin do this. Approval of the idea expressed by Georgia, Iowa, Texas, Nevada. Minnesota hopes to begin such a program this fall.

No. 5. Have you a public health league or similar organization which develops contact between the profession and the public?

Fifteen states have, including Minnesota.

No. 6. Have you a state hospital for medical and surgical cases and if not through what channels are the poor in your rural communities cared for?

Twelve, including Minnesota, answer yes. Sixteen provide community care only. Six have an insane hospital or none.

No. 7. Are your hospital facilities for indigent tuberculous cases ample?

Yes 10; fair 10; no 10. No tuberculous cases requiring hospitals 2.

No. 8. Grouping together osteopaths and chiropractors, what is their percentage to medical men?

Unknown, 7. The balance of the states run all the way from 3% to 50% in Wisconsin. In Minnesota the proportion is about 20%.

No. 9. What are your state activities along the lines of child welfare?

Every state that answered is active in this line.

No. 10. Any other information showing points of contact between the medical profession and the public would be greatly appreciated.

Five states have lecture programs. One state offers occasional lectures and one gives state clinics. Kentucky, Georgia and Wisconsin have systematic public press articles.

If we analyze conditions in Minnesota from the standpoint of contact between the medical profession and the laity we find some satisfactory conditions as well as the reverse. Co-operation on the part of the state legislature is very far from what we could desire. Local county society legislative committees were organized two to three years ago and should be continued. The committee on legislation of the state association is helpless without general co-operation throughout the state. These committees should be active in the pre-election period.

We find two lay journals in Minnesota devoted to public health matters—one published by the Minnesota Public Health Association—the Northwestern Health Journal with a subscription list of over 10,000. This journal deserves the support of every physician in the state and should be in every doctor's waiting room. The second journal is the Popular Health Magazine which is privately owned and exists for private gain.

The Minnesota Public Health Association deserves more than passing comment.

In 1903 the Minnesota Anti-Tuberculosis Association was organized. In 1907 they had a paid executive secretary. In 1915 the name was changed to the Minnesota Public

Health Association. It is financed entirely through the sale of Christmas seals and this income this year was over \$100,000.00. Their activities include:

Clinics—tuberculosis, pediatrics and public health.

Tuberculosis clinics are conducted by county sanatoria men.

Pediatric clinics by specialists whose expenses are paid by the association. The public health clinic consists of a doctor and nurse who travel over the state in a Ford truck provided the counties have sold enough Christmas seals to pay expenses.

Four public health nurses were in the field this summer. Health exhibits are loaned as occasion demands. They try to have them at local county fairs as well as at the state fair. They also send a health clown to these fairs.

Dr. Lohead will give health lectures anywhere in the state.

They distribute much public health literature free of charge. They publish at a loss the Northwestern Health Journal with a circulation of over 10,000.

The matter of radio broadcasting in Minnesota on public health matters by the medical profession has been a storm center of discussion. The consensus of opinion is that the name of the speaker shall not be announced unless he is a full-time teacher or public health worker and not engaged in the active practice of medicine. Your committee is convinced that to allow a relatively small number of active practitioners, whose names are announced over the radio, to broadcast public health talks, would create bad feeling and is not good policy. Five states or county societies broadcast public health talks and four states expressed approval of the plan. Your committee warmly endorses the plan if properly safeguarded. The two stations in Minneapolis have discontinued but if either of them reopens, broadcasting will probably be done under the auspices of the Statewide Publicity Committee. There are in our state 128 nurses doing public health work exclusive of the Twin Cities and Duluth. There are forty-six county nurses and thirty-seven counties have no nurse. These nurses are paid by various agencies—the local county commissioners, school boards, Red Cross or Minnesota Public Health Association. Olmsted county has a county health nurse, infant welfare nurse, a county maternity nurse and a school nurse.

Thirty-seven counties of the state support fourteen county tuberculosis sanatoria. This is in addition to Walker.

Minnesota is one of the twelve states out of thirty-four which are equipped to care for the indigent sick both general and tuberculous.

Some interesting features of work along these lines have been worked out in other states. The Ohio Public Health Association is the chief medium of contact between the profession and the laity. In addition they have a public health federation including dentists, druggists, nurses, hospitals, the public health association and physicians.

In Kentucky the county medical societies work in close co-operation with the Bureau of Child Hygiene and the State Board of Health. All local clinics are under supervision of the county medical societies. The State Medical Association and the State Board of Health are closely coordinated. The State Health Officer is the secretary of the State Medical Association, and therefore the state association guides the activities of the State Board of Health, which is the legal aim of the profession and is so recognized by the legislature and the public.

In Colorado the Denver City and County Medical Society conducts monthly public health lectures. They have a Colorado association for the protection of public health composed of many prominent laymen as well as doctors.

Massachusetts. "It is only a few months ago that our society first took up this matter of contact between the profession and the public, and we have spent most of our time investigating the possibilities. So far we are depending upon lectures which we insist shall be constructive, not argumentative, and the block material for the county newspapers. We are making contact through parent-teachers' associations, women's clubs, labor unions and any place

where they may want a lecturer. Each district society is asked to hold an occasional meeting in their district."

In Georgia they have a statewide health association composed of the state chamber of commerce, bankers, railroads and the medical profession. Also a state health council composed of medical associations, Red Cross, the tuberculosis association, Kiwanians, Rotarians, women's clubs, state agricultural society and Physical Education Association.

Texas. The medical profession is raising a considerable sum of money for a publicity campaign in order to gain public and legislative support.

From a study of the answers received one is impressed with the general recognition of the idea of the advisability of our profession developing contact with the public along public health lines. The basic underlying principle is to strive for an intelligent public viewpoint toward the medical profession.

Individual members of your committee have repeatedly had the idea of effort along these lines held up to ridicule by high grade medical men. They say that we are not in a position to do anything as long as we harbor crooks and abortionists and ignorant doctors in our medical societies and allow them to practice medicine.

They say get rid of them first and we can present a clean front to the public and propaganda will not be necessary. Then they add, "How are we going to do it?"

Such types exist in all professions. Your committee believes that the same principle that governs in the acceptance of a life insurance applicant, namely a confidential report on the moral hazard involved, should also govern in the selection of candidates by the medical schools, namely, a confidential report on character. Those who cannot measure up to established standards should be rejected.

However, if we allow the public to rate the entire medical profession by its relatively few crooks we commit a gross injustice to ourselves.

RECOMMENDATIONS

(1) That local committees on legislation be continued in every county society in the state.

(2) That local committees on public health in every county society take an active interest in all local public health matters.

(3) That radio broadcasting on public health matters be undertaken as soon as possible under the auspices of the statewide publicity committee, that such talks be announced as being given under the auspices of the Minnesota State Medical Association and the _____ County Medical Society, but that the name of the speaker shall not be announced if he is engaged in the active practice of medicine.

(4) That the Minnesota Public Health Association be asked to broaden the scope of their work to include the sending of selected articles on public health to the newspapers of the state at regular intervals and to obtain the newspapers' co-operation for their publication.

(5) That the association indorse the Northwestern Health Journal and permit the management to state that it is the official journal for the public of the Minnesota State Medical Association.

(6) That the secretary of the Minnesota State Medical Association transmit to the Board of Regents of the University of Minnesota, the recommendation of their House of Delegates that in addition to educational requirements to the medical school the character of applicants for admission be ascertained by confidential reports and that those not measuring up to a proper standard be rejected.

(7) That the state medical association continue their part in the State Fair Public Health exhibit.

DR. GEO. D. HEAD: It seems to me that we have had a number of reports made this afternoon by various committees in which recommendations have been made. I would like to move in accepting the report of this Committee that when we have completed our business for the afternoon the House of Delegates form itself into a Committee of the

Whole to take up the recommendations in the order in which they were presented by these various committees and act upon each recommendation separately.

DR. J. C. LITZENBERG: Something of the same thought had entered my mind on account of my one year's experience in the American Medical Association. All of these reports are referred to special committees which are appointed beforehand, and those reports are digested by the committees and a condensed recommendation brought back by the committee. It saves the trouble of the committee as a whole and saves time in acting upon them. I wonder if there is any provision, Mr. Secretary, for regular recommendation of these reports to committees. Is there any such provision in the by-laws and constitution?

THE SECRETARY: There was a provision made last year for reference committees for recommendations of this sort to be referred to. Of course all these reports are not recommendations of committees, and all that we are doing is to refer the recommendation of one committee to another committee. Reference committees may be appointed at the wish of the House of Delegates or at the discretion of the President.

DR. J. C. LITZENBERG: Then I think the purport of your motion would be that this be referred to a reference committee on public health.

DR. GEO. D. HEAD: No, I believe there are immense advantages in organizing ourselves into a committee of the whole. I am inclined to think we will have time to do that very thing this afternoon. We have certain standing committees, haven't we?

THE SECRETARY: We have certain standing committees which act as reference committees.

DR. GEO. D. HEAD: Could those standing committees be read—could those reference committees be read?

THE SECRETARY: The reports we are having this afternoon are the reports of the standing and reference committees. For instance, the committee for which Dr. Adams read the report, on sectional work, was a reference committee.

DR. GEO. D. HEAD: That is, some of the standing committees would be reference committees? If the motion was made to refer these matters to the reference committee it would mean referring them back to the same committee again in many instances?

THE SECRETARY: No, a new reference committee could be appointed.

DR. GEO. D. HEAD: Well, I think, Mr. President, that I would like to renew my motion. I believe it would be wise for us to try out this and see if we cannot act as a committee of the whole upon these valuable recommendations of these committees. It does seem a shame, as Dr. Litzenberg has said, to have such fine reports as we have had made here today and simply in a perfunctory way put them on file and not express ourselves in relation to the recommendations.

DR. W. F. BRAASCH: I think that the plan as suggested by Dr. Litzenberg is an excellent one. As adopted by the American Medical Association, theirs is a large and unwieldy body and it is very difficult to dispose of business. However, we have comparatively a small amount of business, we have a small assembly here, and therefore I wish

to second Dr. Head's recommendation that we act as a committee of the whole.

DR. J. C. LITZENBERG: Did you mean to consider all recommendations of all the committees?

DR. GEO. D. HEAD: Where recommendations have been made. In some of the reports there were no specific recommendations.

(Motion duly carried.)

THE CHAIRMAN: The Statewide Publicity Committee by Dr. Pearce.

REPORT OF THE STATEWIDE PUBLICITY COMMITTEE

This Committee has been comparatively inactive during the past year.

"The Northwestern Health Journal," which was fostered by the Minnesota Public Health Association and this Committee, is prospering and has an ever-increasing list of lay subscribers. The material in the Journal is very high class and is designed to reach the ordinary reading public.

"The Popular Health" is a new magazine now being published by the former editor of the Northwestern Health Journal, and is very much the same type of journal. It is at present in no way sponsored by any medical society or medical group, but the material is being submitted by the editor to various medical men, who are members of this society, and is uniformly good. The editor is anxious to have a committee from the State Association officially censor the material and the advertising in the magazine. This magazine is rapidly reaching a wide circulation, the editor informs now something over 15,000. It has been sponsored by the dentists of the state to the extent that they are all subscribers, and the dental material is being carefully censored by a group of dentists.

Among other publicity activities of the Committee was the radio broadcasting program. After consultation with the president, Dr. MacLaren, and the counselors, an agreement was entered into with the Dayton Company for the broadcasting of a program of popular medical topics. The program was prepared and the topics were to be given out as under the auspices of the State Medical Society, naming also the County Medical Society of which the man who prepared the talk was a member. In our agreement with the Dayton Company, there were to be no names mentioned, the talk simply being sponsored by the State and County Societies. Owing to suspension of operation by the Dayton Company and the WLAG broadcasting station, the program was not carried out. The Committee would like to know, at this time, the sentiment of the Society on the propriety, the feasibility and value of such a broadcasting program. While no advances have been made, it is possible that the new, large broadcasting station, now in the process of construction by the Washburn-Crosby Company, could be induced to give us a place on their program. If the program had been carried out, as intended, the outlines for the various talks would have been submitted to the members of this Society throughout the state, they being asked to write a popular article on the subject which would either be broadcast from the station by the author or a substitute when the author could not be present. The author's name would not be mentioned, but the article would be published in the state medical journals giving credit to the man who prepared the article.

The Committee was also interested with the Public Health Committee of this Society in promoting interest in the State Fair Health exhibitions. We believe by the showing of a little interest that the whole health program of the State Fair could be put under the auspices of the State Medical Society and the University Medical School, and that it would be a very fine form of publicity and public health work for the Society.

As the publicity work of the Society must largely be carried on under the guise of public health, there is an overlapping duplication in the existence of two committees such

as we now have, the Public Health Committee and the Statewide Publicity Committee. Therefore, it is the desire of the Statewide Publicity Committee that this Committee be discontinued as a separate committee and be continued as part of the Public Health Committee.

N. O. PEARCE, M.D.,
Chairman Statewide Publicity Committee.

DR. N. O. PEARCE: Since this report was written, the Washburn-Crosby station, this new station, has approached the Hennepin County Medical Society and the Ramsey County Medical Society with a proposition to have them take over the control of all public health and medical broadcasting from the station. They have offered to place the entire matter in the hands of the committee appointed by those organizations, at the same time requesting that the state organization either endorse or enter into the agreement. They have agreed to give us as much time as we desire, specifically stating at this time fifteen minutes between eight and eight-thirty on each Wednesday evening. I also wish to say that "Hygeia" or the health magazine of the American Medical Association have now a radio broadcasting department and they are prepared to furnish a great deal of the material that would be broadcast as medical subjects. The Hennepin County Society, or their board of trustees, have appointed a committee, and the intent is now pretty much to use the broadcasting material furnished by the American Medical Association, and to have timely talks by men who are in full time public health work, in addition. I think it would be a very important thing for the House of Delegates to consider this question of radio broadcasting and to enter into a committee co-operation with the Hennepin County and Ramsey County societies who are prepared to go ahead with this program.

(Moved, seconded and carried that the report be adopted.)

THE CHAIRMAN: Dr. Ritchie is here and will report on the Annual Congress of Medical Education, please.

REPORT OF THE REPRESENTATIVE TO THE ANNUAL CONGRESS ON MEDICAL EDUCATION, MEDICAL LICENSURE, PUBLIC HEALTH AND HOSPITALS

Fortunately for the delegate to the Annual Congress on Medical Education, Medical Licensure, Public Health and Hospitals, the press of the American Medical Association is now incorporating the proceedings in pamphlet form, which this year includes 102 pages of closely printed material.

Formerly, the delegate attempted to scan the proceedings in a report, an attempt which you can appreciate would be of little value. Those of you interested in medical education, will find most interesting discussions upon policies in undergraduate teaching, in postgraduate teaching, in medical extension work, all incorporated in this extensive report. Similarly, those interested in the problems of regulation of practice by law, the relation of the profession to the various sects and cults in healing, will also obtain much information. Those of you particularly interested in hospital service will find much upon the measures which indicate efficiency in hospital administration, the wonderful information and plans for increasing the autopsy percentage and also its effect upon the demand and supply of interns. Those of you interested in public health will find various plans for periodic health examinations, organization of county medical societies for the dissemination of information for the benefit of the public.

In every former report, your delegate has been most enthusiastic concerning the high plane of the papers as well as the splendid personnel of the meeting, including, as it

does, presidents of universities, deans of medical schools, head masters in various departments of the teaching profession. This meeting is open to anyone, and everyone is always made most welcome. It meets every year at the same place, the Congress Hotel, Chicago, and usually at the same time, early in March.

Respectfully submitted,

HARRY P. RITCHIE.

(On motion duly seconded and carried the report was accepted.)

THE CHAIRMAN: Any new business?

DR. F. S. WARREN: Before we adjourn this meeting I would like to say a few words on the Harrison Act and that recommendation to put the tax back to one dollar as it was before the war. It seems strange to me that the doctor should be called upon to pay any fee at all, and I would recommend that we ask that the fee be entirely abolished. I note that in the American Medical Journal, for January 24 I think it was, of this year, it was stated that it was probably necessary to put a one dollar tax with this law so that it would be perfectly legal. Well, now, why the profession should carry that law when it is a law calling for the reform of the whole country, I cannot understand. If the people want that law why doesn't the payment for its enforcement come from the general treasury? I understand that in 1922 \$613,000 in excess of that necessary for enforcing that law was collected, and that was paid to the general treasury of the United States. If so, we are being taxed excessively. I would recommend that that tax be entirely wiped out, and let the general treasury of the government carry the payment.

THE CHAIRMAN: If there is nothing further in the way of business we can take up these recommendations.

DR. W. F. BRAASCH: I would like to bring before your attention a matter which has interested me a great deal in the last few months and that is a progressive step which has been taken already by eight state associations, namely the adoption of a full time secretary. Unquestionably this is a movement which is necessary with the changing conditions and the many demands upon the State Medical Association. In the suggestion I do not wish to criticize in the least the present secretary, who has done so well, nor the management of the journal, which is also ably conducted; but there are so many demands for the secretary and so many opportunities for a man who can devote his full time to the work that it seems to me we should seriously consider the adoption of such a provision.

I wrote to Dr. West, secretary of the A. M. A., for information on this subject and he told me that there are already seven states, and possibly eight, that have adopted the full time secretary. It has been their experience—and some of them have had it for two and three years—that it has been of the greatest benefit to the state medical association. He also said that in his opinion any state association with a membership of more than fourteen hundred (and we have almost two thousand) should have a full time secretary in order to be most efficient.

I wrote to several of the secretaries, particularly the Ohio State Medical Association, which association has a full time secretary since three or four years even, and he writes me a letter from which I will quote liberally. (Reads letter.)

And now from the secretary of the State Medical Society

of Wisconsin I have also a letter which points out a number of advantages of a full time secretary. (Reads.)

The executive secretary could work with the laity on matters pertaining to public health and the amalgamation of various organizations that are already functioning, economy of concentration of one man, and he could also remain as the editor of the journal, and he could act in an advisory capacity. As it is now, the chairman of the various sections each year is appointed and discharged, and his experience is lost. A new man who has had no experience is supposed to carry on the work, and under his guidance, which will be continuous all the year, he will have a better opportunity to be of aid.

Now, as I said before, we have an excellent secretary; we can not criticize the work of our present secretary, but it stands to reason that a man who can devote all his time to the work and with established headquarters can accomplish a great deal more. He can also help to round up some five or six hundred physicians, I am informed, who are not members of this association; and he can organize and revive the county medical societies and help them in a thousand and one ways. Therefore I would present this matter first for your consideration.

DR. W. A. JONES: May I ask a question as to the expense of such a man?

DR. W. F. BRAASCH: In regard to the expense of such a move, it would unquestionably mean an increase in the society dues. It will entail an expense of possibly five thousand dollars for the salary of such an executive full time secretary. Several of the states have employed laymen, claiming that a layman will have possibly greater business ability and will be in closer touch with the public, particularly a layman who has had some newspaper experience. However, this is not necessary at all. We already have the journal taken care of and at a very economical rate. I think there are advantages in this state under these peculiar conditions in having a physician rather than a layman. I believe, however, that we could not hope to have any physician of ability to officiate for certainly less than five thousand dollars.

As to the method of meeting this large increase, we are now paying five dollars; of those dues two dollars are being devoted to legal defense. It is a matter which unquestionably should be brought up for consideration also before this body, and it already has been brought up for consideration: whether or not we are justified in continuing this legal bureau and whether we are getting value for the money expended. It seems to me that it does not officiate at all as it should. We are paying two dollars for something that we do not get except in a limited way. We really have no legal defense at all as far as that goes, except that we have attorneys, but there is no compensation offered. Furthermore, there are a number of arguments which could be brought up to obviate that. Take these two dollars and apply them toward the secretary's salary. It would mean an increase of a comparatively small amount in the present dues, possibly two dollars more, so as to make the present dues seven dollars. I am sure it has been the experience of the men that I have talked to in other state societies and of the secretaries that the members of the society more than feel repaid for the extra expense by the increased work that

the state society does and by the great increase of influence it has upon the laymen.

DR. J. G. CROSS: If Dr. Braasch makes that as a motion, I suppose the committee as a whole ought to vote on it.

DR. W. F. BRAASCH: We have a contingency which arises now which should be met, namely, you have heard that our worthy secretary has offered his resignation, and I think it has been accepted. He is, however, willing to continue until January 1st in his present position, so we have until January first if the society wishes, to consider and to adopt, at least tentatively, such a program.

DR. J. G. CROSS: Would you think that this was a matter to be referred to the Council?

DR. H. M. WORKMAN: In explanation I will say that this matter came before the Council and the president of the Council appointed a committee to consider or to see for what they could secure a full time secretary. I am not in a position to say what we would have to pay, but there was a committee appointed by the Council, if the House of Delegates should approve the securing of a full time secretary, to see what one could be secured for and to have him begin work then after the expiration of Dr. Drake's time. That would do away with electing a secretary, if the House of Delegates will approve the recommendation of Dr. Braasch. In order to get it before the house, I would like to move that Dr. Braasch's recommendation be adopted.

(Motion seconded.)

DR. H. L. TAYLOR: I would like to ask Dr. Braasch what the dues are that are paid by the Wisconsin State Medical Society. I asked about that during recess at noon and I understand that they are paying fourteen dollars.

DR. W. F. BRAASCH: I am quite certain that you are wrong. The dues in the Ohio State Medical Society are nine dollars, and the dues in the Wisconsin Medical Society are eight dollars, as I was informed.

DR. H. L. TAYLOR: I was very credibly informed that they are fourteen at the present time, and that the Ohio State Medical Society has a very much larger membership. As far as organizing the state organization is concerned, we are thoroughly well organized, with over nineteen hundred members and six hundred practitioners that are not members. I would like to know how many of those six hundred we would be willing to receive even if our full time secretary rounded them up.

DR. W. F. BRAASCH: I am quite certain that you are mistaken as to the fourteen dollars, Dr. Taylor. I am sure that the dues will not be more than eight or nine dollars at the most, and I believe that with this cancellation of the clause for legal defense they can be reduced to seven dollars surely. As you say, unquestionably the journal is well taken care of by Mr. Bruce; and in talking this over with the Council and others, we felt that we ought to continue Mr. Bruce in his present capacity. That will of course reduce the work of the secretary, but will give him a greater opportunity for lay work and for coordinating these various organizations that are now uncoordinated and that are overlapping. I think you will have to leave it to the judgment of the committee from the Council, if you adopt this motion, to see that the dues will not be exorbitant, that they will not be more than nine dollars.

DR. W. A. COVENTRY: Might there not be a difference

of understanding on that? Eight dollars state dues, but fourteen dollars county dues of which eight dollars is for the state.

DR. C. B. WRIGHT: Wouldn't it be advisable to settle this first in the local societies? A few of us who are interested in the local societies find that at present the dues are getting a little strong. I think it might be advisable to have this matter presented for endorsement by some of the local societies before it is carried out. I rather think that at the present time many of the local societies wonder what they are paying all this money for. I have heard that criticism many times, and I believe that some method ought to be used to sell this thing in an enthusiastic way to the members of the local organizations. That is my experience. Personally I have heard that criticism, and if you are going to raise the dues without first getting the endorsement at least to some extent of the local societies who make up this organization, I think we may find a difficulty in putting it over.

DR. L. SOGGE: I fully agree with this last speaker. I for one will not be willing to vote before I know what it is going to cost. A good many of us did that a few years ago and we have suffered a whole lot for it. So I would like to know what the dues would be if we had a full time secretary before I would want to vote on it, and I think it would be pretty hard to vote until I had referred it back to my own society. I think that we ought to have a vote from the local society first and know how much the dues are going to be and then vote on it in the society, because if we raise the dues very much I am afraid we are going to lose some of the members down in our section of the country. I am not sure now of the percentage but I believe that about seventy-five per cent of the men down there are carrying individual liability and still they are paying those dues into the society every year, and they are getting tired of it. They have absolutely no benefit from that liability, because I know there have been quite a few suits down in there brought for malpractice but they all used their individual Fort Wayne insurance that practically all of them carry. I think it would be a good thing if we take away that liability insurance, and if it would not raise the dues very much I think the full time secretary is a mighty good thing, but we do not want the dues too high.

DR. H. M. WORKMAN: I want to just say one word in explanation for the Council. I do not think it is the idea of the Council to ask any increase in the dues at this time. What the Council appointed the committee for was to see what they could secure a full time secretary for under our present assessment, not to increase the dues until we come back to you with what it can be done for with the present assessment. This two dollars for insurance will have to be enforced for six years, even if we repeal it now, until the expiration of the liability occurs. Any man who is now a member of this society, even if we stop the insurance at this time, would have to be defended for the next six years, and we would have to keep up this two dollars for six years anyway.

If we can get a full time secretary and continue the dues what they are now, why we will be that much better off; and that was the idea of the committee that the Council appointed to investigate this matter and see if we could

not find somebody to do that for the time being until we got this thing going.

THE SECRETARY: Inasmuch as I have been the secretary for four years and am retiring, I just want to say a few things in regard to this proposition. I was one of the committee appointed with Dr. Braasch and Dr. Workman to present this thing to the House of Delegates for the Council. There isn't any question in my mind but what it would be much better for the association and its affairs in every way to have a full time layman to handle the business side of the association. Other associations have had great difficulty in getting just the right type of man to do that, a man who will go out and help county societies organize and help increase the membership of the association. It is doubtful in my mind whether we could get a man who was worth while to do that for less than five thousand dollars. That means five thousand dollars more than the hundred dollars a month that we are paying now. We are paying one hundred dollars a month, which is a ridiculously low sum for organization purposes, that is, for somebody to handle and keep track of the membership and all the details. That is just twelve hundred dollars a year.

Now if you had a high salaried man, that is, a man with a four or five thousand dollar salary, he isn't going to work the typewriter; he isn't going to keep all these records. He will have a stenographer, and you can't get a stenographer nowadays for less than a hundred dollars a month who is worth anything. Another item is rent; and you can't get an office for less than forty or fifty dollars a month. You will incur a rather big expense.

There isn't any question in my mind but what this is a fine thing, but I really think that a committee ought to be appointed to go into the financial side of it and consider it thoroughly before any action is taken. I would be in favor of it, and I would be willing to pay nine dollars, which is the figure that I got from Wisconsin a year ago at Chicago at the secretaries' meeting when I spoke to the executive secretary of the Wisconsin Medical Association. He said that the dues had been raised from four to nine dollars. He also said that the advertising in the state journal was so much more since he had become executive secretary that such a marked increase in the dues would not have been necessary. In putting this proposition into effect in Minnesota we are not considering putting this manager in charge of the journal too, so that this is no argument for adopting such a measure.

I really think that the solution of this problem is to find out exactly how much money it is going to cost. The state association was only five hundred dollars ahead of the game this year, which is pretty close sailing. To attempt what looks to me like a seven or eight thousand dollar proposition ought to be looked into pretty carefully before it is adopted, because I am afraid the members of the state association may not think that they are getting their money's worth if we raise the dues to nine dollars.

DR. W. F. BRAASCH: This is from the secretary of the State Medical Association in Wisconsin. I should have read it before. (Reads letter.)

And may I also say that it was my original intention to bring this merely for your consideration, but in view of the fact that the first of January we will have no secretary and will have to hunt around to get one temporarily at least,

it appeared to the Council that this might be an opportunity to try out this method.

DR. C. P. WRIGHT: I do not want to be misunderstood on this proposition. I am absolutely in favor of it. I think it would be a wonderful thing for the entire medical profession in Minnesota, but I still believe that it would be better to approach the matter in a way so that everyone will understand exactly what that is for and the local organizations be entirely in sympathy with it. I believe you can work up such a sentiment, and I think it would be a tremendously valuable thing if you can do it. Now I would like to make a motion that this recommendation be referred to the local societies which are component parts of this organization for their endorsement.

(Motion seconded.)

THE CHAIRMAN: There is a motion before the house, I think, now.

DR. W. A. COVENTRY: May we have the motion, please?

THE CHAIRMAN: Dr. Braasch, will you make your motion again?

(The Secretary read Dr. Workman's motion as follows: I would like to move that Dr. Braasch's recommendation be adopted.)

DR. W. F. BRAASCH: Let me repeat the body of my recommendation in a few words: That the committee appointed by the Council be allowed to continue in the investigation as to the ways and means of financing a full time secretary, and if in their judgment it is feasible that he be appointed to take the place of the retiring secretary without an increase in dues.

THE CHAIRMAN: Without an increase in dues. Is that all understood? Are you ready for the question?

(The motion having been declared carried in the usual manner, there was call for a rising vote, which being taken, showed twenty-four in favor and twelve opposed.)

DR. C. B. WRIGHT: I move that this motion be referred to the local societies for their endorsement. The reason I say that is because I think it is a good thing to get the local societies in on this. I have had a little experience with one society, and you want your society back of you. I believe there are a good many men here who will agree that if you can get co-operation from your local society you will get much further. Therefore I make that motion.

(Motion seconded and carried.)

THE CHAIRMAN: Now the recommendations that we have here in these papers will be taken as the Secretary comes to them.

DR. J. G. CROSS: I beg your pardon, are we now a Committee of the Whole?

THE CHAIRMAN: Yes.

THE SECRETARY: The matter of the physicians who have become incapacitated or are in straitened circumstances. It was the consensus of opinion in the Council that this matter should be taken up before the House of Delegates. I might state in connection with this that I received a communication from Dr. A. W. Ide, of St. Paul, written when Dr. Beebe was a patient at the Northern Pacific Hospital in St. Paul. He stated that the situation was really brought to his attention by the case of Dr. Beebe. Dr. Beebe was in need of financial help, and the thought occurred to Dr. Ide that it would be a fine thing if the Minnesota State Medical Association could start a fund to provide for mem-

bers of the association who are in straitened circumstances, due to sickness or accident or old age. A letter was written by Dr. Ide to Dr. MacLaren, and Dr. MacLaren being ill was unable to act upon the situation, so the copy of the letter was sent to me, and I thought it only proper to bring it before the delegates. Reference was made to an article which appeared in "Clinical Medicine" on a proposition which had just been undertaken in New York State where a country place was presented to the society which was gotten up by the doctors of the state to provide for such unfortunate members of the profession. The idea of this New York society was to have it of rather national scope, the New York society being the first unit to be established. I am simply bringing it to your attention. I don't know whether it has ever been brought to the attention of the state medical association before. I am not going to put it in the form of a motion, but if anybody believes that this is worth while or advisable it seems to me a motion would be in order to perhaps refer it to a reference committee.

DR. GEO. D. HEAD: Would a motion be in order to refer this matter to the Council with power to act or set aside a certain sum for this purpose out of the money available?

THE CHAIRMAN: I think so. I think that if the House of Delegates so ruled the Council would have authority to act.

DR. GEO. D. HEAD: I would make such a motion, that we refer to the Council with power to act the matter of setting aside a specific sum of money to assist members of the association that are in real need.

(Motion duly seconded and carried.)

DR. J. G. CROSS: Before we are too far along in this, may I ask the Chair to rule whether in committee of the whole it is proper to provide for the sending of a message of regret to our President? That, it seems to me, ought to go forward without any delay. I would move you that the Secretary be instructed to send a message by wire to the President, Dr. MacLaren, suitably expressing our regret that his illness prevents his being among us.

(Motion seconded and carried.)

THE SECRETARY: These are the recommendations from the report of the Committee on Public Health: (1) That local committees on legislation be continued in every county society in the state.

(Motion to adopt recommendation seconded and carried.)

THE SECRETARY: (2) That local committees on public health in every county society take an active interest in all local public health matters.

DR. C. L. SCOFIELD (Benson): I believe that in most county societies there are no such committees and that it would be advisable to change that to provide for such public health committees in county societies and then add this recommendation do it. If I am correct in that statement, I would move that county societies be requested to appoint public health committees and that these recommendations be followed.

(Motion seconded and carried.)

THE SECRETARY: (3) That radio broadcasting on public health matters be undertaken as soon as possible under the auspices of the statewide publicity committee, that such talks be announced as being given under the auspices of the Minnesota State Medical Association and the County medical society, but that the name of the speaker shall not

be announced if he is engaged in the active practice of medicine.

I might say that in the report of the publicity committee they have recommended that their committee be terminated. We ought to take that into consideration in acting on this.

DR. FRANK SAVAGE (St. Paul): May I have the privilege of the floor? I am not a member of the House of Delegates. This matter has been a regular storm center of discussion. It has been threshed out in Hennepin County; it has been threshed out in Ramsey County. The general consensus of opinion is that it would create bad feeling if a certain few were selected and their names were announced. The viewpoint of the radio corporations up to this time, especially WLAG, has been that these talks are of no value unless the names are announced. Dr. Wright's viewpoint on that was to let them come to the viewpoint of the medical men or not get the material. They have been very anxious to get the material. Now as Dr. Pearce has stated today, they are ready to accept this proposition, and it is the idea to establish these radio talks to be given under the auspices of the State Medical Association sponsored by some county medical society, and make the radio companies either take that or we will not give the talks to them, and establish that principle in order to create good feeling and not bad feeling. It doesn't make any difference under whose auspices this is undertaken, but I would like to see that principle established; that the name of the speaker be not announced if he is engaged in the active practice of medicine. I think that is a very important thing, and those who have given it time and thought I think are unanimous in that conclusion.

DR. C. B. WRIGHT (Minneapolis): In Hennepin County we had this matter before us the last two or three years. How it came up first was through the request of a number of men who are on the fringe of the medical question who asked us to allow them to talk over the radio. The thing was threshed out very thoroughly. The chairman of the publicity committee took this question up, and this was the only solution of it which we decided would be without discussion and would create no feeling. For instance, as Dr. Fishbein said in his talk in Minneapolis, he gave a talk himself, a full time man in the employ of the American Medical Association, and the next morning he had twenty-five or thirty calls over the telephone and letters asking him for a consultation in his office. The whole thing is new, and it seems better to approach it from a perfectly safe standpoint. As there are probably fifty men in full time work in this state, through the University and other places, it seemed to us that this would be the advisable thing to do.

Now as you know Washburn-Crosby have taken over WLAG, and through the help of public spirited citizens of Minneapolis and St. Paul, who have contributed a large amount of money, they are putting in a very expensive radio which, when completed, will broadcast all around the world. We had a consultation with them, Mr. Wilbur and Major Harrison, who are directing this thing, and they are very anxious to co-operate with us. They are anxious to put on something which will be of real service to the Northwest in the way of market reports and various other things which will be of value. They are not so particular about whether it is going to be the thing which goes over quick;

they want to develop something which is of educational value. They are very willing, I think, that we use the clippings of "Hygeia" which are sent every month, reinforced by talks by various public health men on subjects of live interest. They are very anxious to co-operate, and I think it would be a great mistake to step backward, because we have got to the point where we must advance.

(Motion to adopt the third recommendation of the Public Health Committee seconded and carried.)

THE SECRETARY: (4) That the Minnesota Public Health Association be asked to broaden the scope of their work to include the sending of selected articles on public health to the newspapers of the state at regular intervals and to obtain the newspapers' co-operation for their publication.

(Recommendation adopted.)

THE SECRETARY: (5) That the association endorse the Northwestern Health Journal and permit the management to state that it is the official journal for the public of the Minnesota State Medical Association.

DR. GEO. D. HEAD (Minneapolis): I would like to raise the question as to whether or not it would be wise to state that it is the official journal for our association. Unless we have fairly definite control, I doubt that we ought to allow our name to be published as being represented by this journal or endorsing the journal and having our name put in the journal as its representing us officially. Wouldn't it be just a little bit dangerous perhaps unless we had some way of passing upon or editing the material that goes in? I know the Northwestern Health Journal is a splendid magazine and we all endorse it, but isn't that sufficient without putting our name upon it? I just raise the question.

(Dr. H. M. Workman moved that the association endorse the Northwestern Health Journal but that the second part of the recommendation be omitted. After considerable discussion the motion was carried.)

THE SECRETARY: (6) That the Secretary of the Minnesota State Medical Association transmit to the Board of Regents of the University of Minnesota, the recommendation of their House of Delegates that in addition to educational requirements to the medical school that the character of applicants for admission be ascertained by confidential reports and that those not measuring up to a proper standard be rejected.

DR. GEO. D. HEAD (Minneapolis): I would like to ask whether or not this matter has been submitted to the dean of the medical school and the dean of the post-graduate school before the recommendation was made.

DR. J. C. LITZENBERG (Minneapolis): I do not know. I haven't heard of it.

DR. GEO. D. HEAD (Minneapolis): Wouldn't it be wise, since this is rather drastic for applicants to the medical school, first to have some advice from the authorities before acting on it, or make it with the approval of the dean? I would amend the recommendation by inserting the words: "With the approval of the dean of the medical school."

(Recommendation adopted as amended.)

THE SECRETARY: That the State Medical Association continue its part in the State Fair Public Health exhibit.

(Recommendation adopted.)

THE SECRETARY: I would like to bring before the house

the question of whether or not the Statewide Publicity Committee is to be discontinued as they wish.

DR. N. O. PEARCE (Minneapolis): As chairman of that Statewide Publicity Committee, my reason for recommending that this committee be discontinued and merged with the Public Health Committee is that there is no distinct line of demarcation between the two groups. Everything that I reported was already touched on in the report of the Public Health Committee. I believe that it is unnecessary and makes a cumbersome machine to do the work if you have too many machines that are working on too closely related subjects. To me it seems there are two distinct things that the Public Health Committee should have to do. One of them is to keep in contact with all public health organizations doing public health work throughout the state, keep in medical touch with those organizations and do what is possible to keep them all up in the proper spirit of activity. The other is the medical propaganda in order to get an intelligent public medical viewpoint. That I consider is the work of the Statewide Publicity Committee, trying to create an intelligent medical viewpoint on the part of the public. At the same time, the work is so closely associated that it would be much better taken up if one committee had charge of this program of public health activity and if that was just a department of the public health committee. Therefore we recommended that the Statewide Publicity Committee as a separate committee be discontinued and be provided for in the appointment of the new Public Health Committee.

(On motion, the Committee of the Whole dissolved and again became the House of Delegates.)

DR. J. C. LITZENBERG (Minneapolis): I move that we listen to the report of the Committee of the Whole. Nothing that was adopted in the committee is of any force until it is adopted by the house. The Secretary can report for the Committee of the Whole.

THE SECRETARY: Gentlemen, certain recommendations have been made by the Committee of the Whole; you all know them. You notice that I am called upon to make the report. I make the motion that the suggestions which have been taken down by the stenographer and which you all know be adopted by the House of Delegates.

(Motion seconded and carried.)

A MEMBER: May I have the privilege of the floor? Dr. Workman suggested that if we discontinue our defense of malpractice we would have to continue defense of those who are in for at least six years. I would like to make a motion that the members of the committee use their best efforts in the state of Minnesota to have some specific legislation passed to limit it to two years as they have in our neighboring state of Iowa and other states that I know of.

(Motion seconded and carried.)

THE CHAIRMAN: What is your further pleasure?

DR. GEO. D. HEAD (Minneapolis): I move that when we adjourn that the House of Delegates adjourn to meet at one o'clock tomorrow.

DR. W. A. COVENTRY (Duluth): Last year we had this same sort of wrangling that we have had this afternoon, all in a friendly spirit, however. It seems to me that the business of this House of Delegates is not handled the way it is in most organizations that I have been mixed up in.

I would like to offer this amendment to the by-laws to be acted on tomorrow: That there be appointed by the president on the first day of the session of the House of Delegates a committee on resolutions consisting of five members to whom shall be referred all recommendations submitted to that session, reporting their findings for action at the last day of the session.

DR. H. M. WORKMAN (Tracy): I will make that the second day of the session.

DR. W. A. COVENTRY (Duluth): I will accept that amendment.

(Amendment seconded.)

THE SECRETARY: I think that is going to mean that the House of Delegates will have to go into a committee of the whole on the second day if that resolution is made. Now all these recommendations have already been thought over for a year before they are proposed to the House of Delegates. Why have another committee to pass on all of this when the House of Delegates is here to discuss these things? It would be well to hold the recommendations over until the next day, but I believe as Dr. Head does that this House of Delegates ought to go into a committee of the whole and discuss these things just the way we have done this afternoon. I am afraid that if we just refer all these recommendations to five men there will be very little chance for any open discussion, which I think is the function of this House of Delegates. If we go into a committee of the whole on the second day—which of course would obviate that—it would mean a long drawn out session on the second day, and I think that ought to be considered.

DR. W. A. COVENTRY (Duluth): My idea was to avoid all this terrible confusion. We do not know what we are talking about half the time. If the committee has this definite recommendation before it drawn up in some sort of form to present to this House of Delegates, you can have it in the committee of the whole if you wish, but you have something definite to work upon. As it is now, it is a question of confusing the stenographer and going back over a lot of pages and not knowing what we are trying to find. It is a question of whether it is better for the committee to work through the year and report to the house or better to report to a special committee and let the committee get things in hand before presenting them to the committee of the whole. I am trying to find some way of getting out of this terrible confusion.

DR. H. M. WORKMAN (Tracy): Well, I second Dr. Coventry's motion. The idea is this: We come here as delegates on the first day with nothing to do, and on the second day we will be denied the privilege of attending any sessions and we will take just as much time the second day as we have taken this afternoon. The members of the Council and the House of Delegates are here to attend the meetings, too, and they are going to be denied that privilege.

DR. W. A. COVENTRY (Duluth): In order to facilitate business a little bit, may I ask Dr. Workman if he would have any objection to having it so that recommendations can be referred to this committee beforehand.

DR. H. M. WORKMAN (Tracy): I don't care when they come in; I just want them so we can discuss them.

A MEMBER: I don't see how a committee of five can display any more intelligence after a consideration of a few

hours than the author of the report did after a year's consideration.

DR. B. W. KELLY (Aitkin): Some recommendations made by one committee may be made in a form somewhat different by another committee. In other organizations any resolution to be put before the house must be submitted to the resolutions committee. If we had such a method we would then do away with the greater part of the confusion we have had this afternoon, and the resolutions committee could have had the report on the first day, could have every resolution in concrete, proper grammatical form and proper construction, ready for consideration, and it could be considered by the committee of the whole as has been done today, but without so much confusion. I believe Dr. Coventry would be willing to amend his own motion to that effect, that all resolutions coming before the House of Delegates should come through the committee on resolutions, the report to be submitted on the first day.

A MEMBER: There is just one little bit of differentiation. There have been practically no resolutions brought in; they have been practically all recommendations. I question whether these recommendations should be referred off to some committee of five men to decide upon after these standing committees have been working on them for an entire year. It is not as though they were bringing in resolutions. These are recommendations for the House of Delegates.

DR. B. W. KELLY: I accept that criticism, Mr. Chairman, and still hold to the idea that a recommendation to be made before this house for adoption should come in the form of a resolution. If these all pass through a standing committee on resolutions which would be in session at the opening of this house and immediately preceding, they could be considering these various matters and report when the preliminary business of the House of Delegates had been concluded. That is to say, by the time the reports of the various committees had been heard, these recommendations could be put in the form of resolutions together with other resolutions that any individual member might wish to submit to the house and would be ready for prompt action then, adoption or rejection by the house.

DR. W. A. COVENTRY (Duluth): There is no question. This is an amendment to the by-laws and it has to lay on the table until the meeting tomorrow. This is just offered for your recommendation and action tomorrow.

THE CHAIRMAN: Any further business?

DR. C. L. SCOFIELD (Benson): Now being in order and in view of what has gone before, I would renew my motion that the Council be instructed to reorganize our list of committees.

(Motion duly seconded and carried.)

On motion the meeting of the House of Delegates adjourned until one o'clock the following day.

SECOND MEETING OF THE HOUSE OF DELEGATES THURSDAY, OCTOBER 9th

The House of Delegates met pursuant to adjournment at 1:00 P. M., and was called to order by the first vice-president, Dr. E. T. Sanderson.

The secretary was instructed to read a summary of the minutes of the previous meeting, which were accepted as read.

The President called for a supplementary report of the Credentials Committee and Dr. Braasch reported the following as in attendance in addition to those present at the Wednesday afternoon session:

Hennepin County—Dr. L. A. Nippert, Minneapolis.

Nicollet-LeSueur County—Dr. S. Ericson, LeSueur.

Ramsey County—Dr. E. M. Jones, St. Paul (alternate for Dr. Geo. Geist).

Upper Mississippi—Dr. J. A. Thabes, Brainerd.

Washington County—Dr. W. R. Humphrey, Stillwater.

Winona County—Dr. I. W. Steiner, Winona.

The next order of business was the election of officers and nominations for president were called for.

Dr. W. A. Jones nominated for president Dr. A. S. Hamilton, of Minneapolis.

DR. G. S. WATTAM: Mr. President, I nominate Dr. W. L. Burnap, of Fergus Falls, for president. The presidency of our Association should be given to a member of this body who is a resident of St. Paul, one year; the next year from Minneapolis, and the third year to a member in the outside districts. We have at this time the right to ask that northwestern Minnesota west of St. Cloud be represented. We have never had a president of this Association. We believe that northwestern Minnesota is entitled to that consideration. Dr. Burnap has been one of the staunchest members of this Association for many years. He is at present Councilor for the First District of this Association. I do not believe that this rules him out of being placed in nomination. I know that he will fill the office of president of this Association well, if he is elected.

As there were no further nominations, the names of Dr. Hamilton and Dr. Burnap were balloted upon, Dr. Burnap receiving thirty-two votes and Dr. Hamilton, eleven.

It was moved that the election be declared unanimous for Dr. Burnap. The motion was seconded and carried.

The following officers were nominated and declared duly elected:

First Vice President—Dr. A. S. Hamilton, Minneapolis.

Second Vice President—Dr. John Libert, St. Cloud.

Third Vice President—Dr. C. W. More, Eveleth.

Secretary—Dr. Carl B. Drake, St. Paul (re-elected).

Treasurer—Dr. F. L. Beckley, St. Paul (re-elected).

Councilor for the First District—Dr. G. S. Wattam, Warren.

Councilor for the Fourth District—Dr. W. H. Condit, Minneapolis.

Councilor for the Seventh District—Dr. F. A. Dodge, LeSueur.

The appointment of Dr. H. Longstreet Taylor, St. Paul, to succeed Dr. W. A. Dennis as Councilor of the Third District, following the death of Dr. Dennis in November, 1923, was approved by motion, which was seconded and carried.

THE SECRETARY: I would like to state that my resignation as secretary of this Association had been accepted prior to this meeting and that if I consent to being re-elected that it be with the understanding that a full-time secretary be appointed to take over this work. I will again tender my resignation at that time.

THE PRESIDENT: We will now take up the election of delegates to the American Medical Association. This year we are entitled to a third delegate to the American Medical Association upon the basis of one delegate to each 950 members. Our constitution provides that the election of these

delegates conform to the laws of the American Medical Association.

Dr. J. L. Rothrock was nominated and declared duly elected as Delegate to the American Medical Association.

The names of Dr. J. F. Corbett, Minneapolis, Dr. T. L. Chapman, Duluth, and Dr. J. G. Cross, Minneapolis, were proposed for election as the third Delegate to the American Medical Association. As the first ballot gave no majority vote, a second ballot was cast, resulting in the election of Dr. Chapman.

Dr. J. G. Cross, Minneapolis, as alternate for Dr. Rothrock, and Dr. Theo. Bratrud, Warren, as alternate for Dr. Chapman, were nominated and declared unanimously elected.

Dr. H. M. WORKMAN: Mr. President, I would like to propose an amendment to the constitution. Whenever the chairmen of the various committees come in here to make their reports they have to ask the privilege of the floor in order to address the House. I would therefore add to Article V—"also the chairmen of the various appointed committees and the delegates to the American Medical Association, but without vote."

Dr. W. A. JONES: I move that the amendment be referred.

Seconded and carried.

Dr. W. H. CONDIT: Mr. Chairman, may I present the matter of the next meeting at this time? I would like to invite the Association to meet in Minneapolis next year.

Dr. C. L. SCOFIELD: It has been suggested that if possible these meetings be held on the University campus and I would like to move therefore that the next meeting be held on the University campus if arrangements can be made to do so.

Dr. W. A. JONES: There are a few difficulties to contend with in meeting on the University campus. The Hennepin County Medical Society has in view something for next year, in which they hope the State Association will join. There is no auditorium on the campus large enough and no auditorium available after September. We have been forced to go outside for an auditorium. This is a very serious objection.

Motion was made, seconded and carried to accept Dr. Condit's invitation to meet in Minneapolis next year.

THE SECRETARY: It will be up to the Council to decide on the time when this meeting is to be held. I have heard that there may be a meeting of the Tri-State Association in Minneapolis in October of next year.

Dr. W. A. JONES: It has not been determined definitely.

THE PRESIDENT: We will now have the report of the Reference Committee. Dr. Braasch.

Dr. BRAASCH: Your committee suggests that the House of Delegates recommend to the next Program Committee that more combined meetings be held and that the program consist largely of clinical presentations and papers read in abstract.

(Signed)

W. F. BRAASCH,
W. A. JONES,
GEORGE D. HEAD.

A MEMBER: I move that the report of the committee be adopted.

Dr. B. S. ADAMS: The papers that we get at the state

medical meetings are helpful and interesting. Would this recommendation mean any curtailing in the character or in the number and quality of the papers we are going to have?

Dr. W. F. BRAASCH: Of course, the idea is that in keeping with the present policy—to hold as many clinical presentations as possible and to avoid the long tedious paper which is devoid, more or less, of interest. This plan gives an opportunity for many more clinical presentations than by the former method. I think there would be plenty of opportunity for what you refer to.

Dr. B. S. ADAMS: I think it would be too bad if we do not have some good papers for our journal.

Dr. W. F. BRAASCH: There would be plenty of material for the journal.

The motion that the report of the committee be accepted was seconded and carried.

Dr. J. W. BELL: Mr. President, in the matter of employing a full-time secretary, I would like to inquire whether the idea of the assembly was to have a medical man. I wasn't quite clear on that point when the matter was brought up before.

Dr. W. F. BRAASCH: It is the intention of that committee to have a physician as secretary.

THE SECRETARY: I wish to ask the opinion of the House on the advisability of having a full-time secretary. Was it the wish of the House that the motion stand as Dr. Wright gave it?

Dr. C. B. WRIGHT: The motion was not in very definite form. It was simply left to the Council to provide ways and means. There is nothing definite to refer to the Society at this time. If a full-time secretary can be procured without increasing the dues there will be no need to refer the matter to the local societies. If the dues are increased, the matter should be referred to the local societies. I therefore move that if it is necessary to increase the dues of the local societies to provide a full time secretary, that this matter be referred to the local societies for their decision before definite action is taken.

A MEMBER: A motion has already been passed that the matter be referred to the local societies. It is a question of whether this should be done by the secretary or the delegates.

Dr. H. M. WORKMAN: I second the motion of Dr. Wright.

The motion was carried.

THE PRESIDENT: Is there anything to come before the meeting under Old Business?

THE SECRETARY: The Legislative Committee in their report brought up a communication received from the American Medical Association headquarters asking that this state association confirm some resolution made by the American Medical Association in order to get more pressure to bear on Congress. I have not had time to go through the material. The Legislative Committee did not leave an outline with me. I think it would be safe to take action to carry out this request of Dr. Woodward.

A MEMBER: I move that the State Association confirm the resolutions of the American Medical Association.

Dr. J. W. BELL: May we have the suggestions of Dr. Woodward?

THE SECRETARY: Dr. Woodward requests that we take

action on the following propositions which have received the approval of the American Medical Association House of Delegates or the Board of Trustees:

The endorsement of a bill now pending in Congress requiring the labeling of packages containing lye and other caustic substance as poison.

A resolution passed by the American Medical Association House of Delegates expressing its disapproval of the portion of the National Prohibition act which limits the prescribing of liquor by physicians on the ground of this being interference with proper relations between physician and patient.

The reduction of the war tax imposed under the Harrison Narcotic law from \$3.00 to \$1.00.

Fostering legislation placing cosmetic preparations under the Food and Drug act.

The creation of a federal department of Education and Relief comprising a Bureau of Public Health and a Bureau of Relief.

Relief for the medical profession, which will enable a physician to charge up traveling expenses to and from medical meetings to professional expense.

DR. W. A. JONES: I move that the secretary be instructed to cast the vote of the House of Delegates.

DR. WARREN: I would like to see the Minnesota State Medical Association go on record as asking that the narcotic tax imposed on physicians by the Harrison Narcotic Act be entirely wiped out. If the United States wants to institute a reform, let the people pay for it. They put a burden on us that does not belong to us. I ask that that fee be entirely wiped out.

DR. W. A. JONES: I move that the State Association go on record as asking that the tax imposed on physicians by the Harrison Narcotic Act be removed.

DR. J. W. BELL: I do not think that the medical profession should ask a modification of the act to allow us to distribute more whiskey and liquor than we do now. I move that that part of the recommendation be stricken out.

A MEMBER: I second the motion.

THE PRESIDENT: That motion is considered as an amendment to Dr. Jones' motion, I believe.

A MEMBER: The morning after this action was taken over by the national association, the Chicago papers said that the American Medical Association had gone over to booze. I think it is high time to show that we have not done that. I do not see any reason for any more liquor than we have, unless we want to assume the duties of the former bartenders. It would be better to cut down the amount instead of increasing it.

THE PRESIDENT: A motion has been made and seconded that Dr. Jones' motion be accepted with an amendment. Those in favor signify by saying, Aye.

The vote was undecided and a rising vote was asked for.

DR. W. A. JONES: I want to waive that motion.

THE PRESIDENT: It cannot now be waived.

The motion was carried by a rising vote.

DR. WARREN: I wish to make my motion that the fee be entirely wiped out instead of brought down to \$1.00 and that the Association go on record as recommending that.

THE SECRETARY: A fee of \$3.00 is now charged for the privilege of dispensing narcotics. Efforts have been made by the American Medical Association at Washington to

bring it back to \$1.00. It would be better to request a reduction of the fee to \$1.00 on the grounds that it is now a tax on the physicians, whereas \$1.00 is necessary as a fee to handle that particular federal regulation.

DR. WARREN: There is no reason why the government should put a fee on us. It is not the amount. We do not want it at all. My opinion is that the whole thing is unconstitutional. Special taxes on physicians show discrimination. Such a tax should be carried by the whole nation. I should like to go on record as being opposed to this tax.

Motion was made and carried that the Association go on record as being opposed to the Harrison Narcotic Act entailing the payment of a fee by physicians.

A motion was made that the incoming president be empowered to appoint various committees.

Seconded and carried.

The President appointed a committee consisting of Dr. G. S. Wattam and Dr. George Douglas Head to notify the incoming president of his election and to escort him to the chair at the afternoon session.

DR. A. C. BAKER: In regard to the medical defense feature: we have to go over a period of five years before the present cases would be taken care of, do we not? I move that this feature be abolished.

DR. H. M. WORKMAN: That is an amendment and will have to lay over a year. This proposition has come before previous meetings. The House of Delegates has voted to retain the feature. It involves a change in the By-Laws and must be laid over until the next meeting.

As there was no further business to come before the meeting, on motion, duly seconded and carried, the House of Delegates adjourned *sine die*.

MINUTES OF THE SURGICAL SECTION

A. C. Strachauer, M.D., Chairman.

Verne C. Hunt, M.D., Secretary.

THURSDAY MORNING, OCTOBER 9th

The first meeting of the Surgical Section was held in the Sherman Theatre, St. Cloud, and was called to order at 8:45 A. M. by the Chairman, Dr. A. C. Strachauer.

Dr. Orville N. Meland, Warren, presented a paper on "The Treatment of Severe Injuries of the Scalp," which was discussed by Dr. H. P. Ritchie, St. Paul.

Dr. H. Waltman Walters, Rochester, read a paper entitled: "Obstructive Jaundice and Studies in Liver Function," which was discussed by Dr. A. A. Zierold, Minneapolis; Dr. A. C. Strachauer, Minneapolis; and in closing by Dr. Walters.

Dr. John F. Fulton, St. Paul, read a paper on "Foreign Proteins as Therapeutic Agents in the Treatment of Acute Ocular Inflammation." This was discussed by Drs. Paul Berrisford, St. Paul; W. R. Murray, Minneapolis; Carl Larsen, St. Paul; and again by Dr. Fulton.

Dr. Gilbert J. Thomas, Minneapolis, presented an essay entitled: "Preoperative Treatment of the Prostatic," which was discussed by Drs. H. C. Bumpus, Rochester; Edward Bratrud, Warren; W. F. Braasch, Rochester; Theodore Sweetser, Minneapolis; and in conclusion Dr. Thomas presented slides.

Dr. C. B. Lewis called attention to the two luncheons arranged for Friday noon, that of the alumni of the Univer-

sity of Minnesota, and that at the Country Club in honor of the ladies and such of the members as wished to attend. He also announced that the Commercial Club of St. Cloud were offering the services of their stenographer, free, to the members of the convention.

Dr. Carl C. Chatterton, St. Paul, presented a paper on "Acute Osteomyelitis in Children," which was discussed by Dr. M. H. Tibbetts, Duluth, whereupon Dr. Chatterton showed slides.

Dr. P. E. Stangl, St. Cloud, read an essay on "Perforating Gastric Ulcer," which was discussed by Drs. H. C. Cooney, Princeton; W. J. Mayo, Rochester; E. M. Jones, St. Paul; Verne C. Hunt, Rochester; A. M. Ridgway, Annandale; L. Sogge, Windom; W. H. Magie, Duluth; B. F. Van Valkenburg, Long Prairie; and in closing by Dr. Stangl.

Dr. Wm. R. Bagley, Duluth, read a paper on "Consideration of Various Abdominal Symptoms and Findings in Diagnosis," which was discussed by Dr. J. P. Schneider, Minneapolis, and again by Dr. Bagley.

Adjournment at 12:45.

MINUTES OF THE MEDICAL SECTION THURSDAY MORNING, OCTOBER 9th

E. L. Tuohy, M.D., Chairman
Chas. N. Hensel, M.D., Secretary

The Medical Section of the Minnesota State Medical Association's 56th Annual Session was called to order at 8:30 A. M. in the Knights of Columbus hall in St. Cloud by the chairman of the section as follows:

DR. TUOHY: There seems to be some misunderstanding as to the meeting hour today, but there is no misunderstanding as to the statement on this program, and you will do the Chairman a courtesy if you will pass the word along that tomorrow morning we shall begin at half past eight if there is only one man present.

The first paper to be read to this section this morning is one entitled "Differential Diagnosis of Pulmonary Disease" by Dr. M. George Milan, of Warren, Minnesota, and I now take great pleasure in calling upon Dr. Milan to address us.

Dr. Milan's paper was discussed by Dr. George D. Head, Minneapolis; Dr. L. A. Nippert, Minneapolis; Dr. H. Longstreet Taylor, St. Paul; and in closing by the essayist.

Dr. Everett K. Geer presented a paper entitled "Artificial Pneumothorax in Acute Lung Abscess," which was discussed by Dr. W. S. Lemon, Rochester; Dr. George D. Head, Minneapolis; Dr. M. George Milan, Warren; and Dr. Geer closing.

The paper on "Liver Functional Studies in Experimental Jaundice" was presented by Dr. A. M. Snell, of Rochester, and the paper on "Liver Functional Studies in Clinical Jaundice" was presented by Dr. Greene, of Rochester.

The two papers by Dr. Snell and Dr. Greene were discussed by Dr. Henry L. Ulrich, Minneapolis; Dr. Waltman Walters, Rochester; Dr. W. J. Mayo, Rochester; and in closing by the essayists.

Dr. F. W. Schlutz, Minneapolis, presented a paper entitled "Diabetes in Children." There was no discussion.

DR. TUOHY (Chairman): Members of the Section, on this occasion I wish on your behalf, as well as my own, in the presence of the Chairman of the local committee, to

thank the committee for the great care they have taken in preparing for us and giving us these splendid quarters and having at our disposal all the means of comfort that we are enjoying. This is the Knights of Columbus hall. I am a member of that order in Duluth, and I am pleased to note in St. Cloud there is the same spirit of religious and political serenity, because these colors above us are the colors of the Ku Klux Klan and it is to be seen that both orders are occupying the same hall as in Duluth. (Laughter.)

We have two more papers which will be discussed at the end of the second paper. First, "Practical Electrocardiography," by Dr. Harold E. Richardson, St. Paul, and "Electrocardiogram in the management of heart disease," by Dr. E. T. F. Richards, St. Paul.

The papers by Dr. Richardson and Dr. Richards were discussed by Dr. R. Edwin Morris, St. Paul; Dr. Olga S. Hansen, Minneapolis; Dr. H. Z. Giffin, Rochester; Dr. Frederick Mitchell, St. Paul; Dr. Henry L. Ulrich, Minneapolis.

Adjournment at 12:15 P. M.

GENERAL SESSION THURSDAY AFTERNOON, OCTOBER 9th

The convention met in general session in the Sherman Theatre at 2:00 P. M., Thursday, with Dr. A. C. Strachauer in the chair.

The program consisted of a symposium of papers on "Cancer" and was introduced by Dr. Margaret Warwick, St. Paul, with an illustrated talk on "Carcinomata as Shown by Paper Models Reconstructed from Serial Section."

Dr. Harold Robertson, Rochester, presented a paper entitled "Some Unusual Features of Carcinoma."

THE CHAIRMAN (Dr. Strachauer): We will now turn to the next paper. Dr. Ritchie for a number of recent years has been coming to our attention, particularly interesting himself in the service on malignancy at the University Hospital, and he has done a splendid outstanding piece of work. Individuals that have come to us regularly and whom we have had to inform that their cases were hopeless and there was nothing that we could do for them and whom we have had to send back home, ever since the doors of that hospital were opened, have sought his help. They have been people who were in a perfectly dreadful condition so far as they were concerned—not caring to live for themselves, let alone living with their families—and Dr. Ritchie has included these people in his series of cases, and we are fortunate in having a little glimpse into some of the work he is carrying on and that is being carried on under Dr. Ritchie in the consideration of destructive and constructive surgery in malignancy. Dr. Ritchie.

Dr. Harry P. Ritchie then presented his paper entitled "The Destructive and Constructive Surgery of Malignancy."

THE CHAIRMAN (Dr. Strachauer): The relative merits of radiolitic and surgical treatment of malignancy are so frequently presented by individuals who are working exclusively in one field or another, and in their great enthusiasm over their work in hand in my opinion overstate it, it is a great pleasure to have an authority like Dr. Mayo, who is so thoroughly familiar with the results being obtained, both in the radiolitic and the surgical therapy, and the results obtained in the combination of these methods, to

present us with the facts on this subject. I will now call upon Dr. W. J. Mayo to address us on the subject of "The Relative Value of Surgery and Radiotherapy."

Dr. Mayo's address was then delivered.

THE CHAIRMAN (Dr. Strachauer): Ladies and gentlemen, the next and last speaker is a member of the University Hospital also. He is pathologist of the University Hospital, thoroughly alive to malignant problems, and for the last half dozen years—possibly less—has given a considerable number of lectures before lay audiences as well as medical audiences. In addition to that he has put on several health shows, both for the University and for the Hennepin County Medical Society, also showing at the State Fair. So you see he has been on the firing line and is particularly qualified to present the subject of what the laity should know about cancer, and this audience knows that that is a subject that we are all interested in, and I want at the end of his presentation that you should feel at liberty to discuss it with Dr. O'Brien.

Dr. William A. O'Brien, Minneapolis, had chosen as his subject, "What the Laity Should Know About Cancer."

The meeting then adjourned.

MINUTES OF THE SURGICAL SECTION

A. C. Strachauer, M.D., Chairman.

Verne C. Hunt, M.D., Secretary.

FRIDAY MORNING, OCTOBER 10th

The second session of the Surgical Section was called to order by the Chairman in the Sherman Theatre at 8:50 A. M.

Dr. W. L. Burnap, Fergus Falls, presented a paper on "The Silent Antrum," which was discussed by Drs. Horace Newhart, Minneapolis; J. T. Schlesselman, Mankato; W. E. Camp, Minneapolis.

Dr. Emil C. Robitshek, Minneapolis, read an essay entitled: "Surgical Accidents in Simple Inguinal Hernioplasty," which was discussed by Drs. G. G. Eitel, Minneapolis; Gustav Schwyzer, Minneapolis; A. R. Colvin, St. Paul; and Arthur N. Collins.

Dr. M. S. Henderson, Rochester, read an essay entitled: "Arthroplasties," which was discussed by Dr. Emil S. Geist, Minneapolis, and Dr. A. R. Colvin, St. Paul, and in closing by the essayist.

Dr. Emil F. Geist, Minneapolis, presented a paper on "Fractures of the Spine." In the discussion the following participated: Drs. M. S. Henderson, Rochester; A. T. Mann, Minneapolis; B. S. Adams, Hibbing; A. R. Colvin, St. Paul; and Dr. Geist in closing.

Dr. D. C. Balfour, Rochester, read a paper on "Relative Merits of the Different Surgical Procedures for Duodenal Ulcer," which was discussed by Drs. A. C. Strachauer, Minneapolis; A. T. Mann, Minneapolis; T. L. Chapman, Duluth; S. Marx White, Minneapolis; C. M. Roan, Minneapolis; and in closing by Dr. Balfour.

A joint paper by Dr. Arthur N. Collins and Fred Ritz, Bacteriologist, Duluth, on "Tracing Infections in a Surgical Service," was read by Dr. Collins. Dr. Wm. C. Carroll, St. Paul, and Dr. Theodore Sweetser, Minneapolis, discussed the paper, after which Dr. Collins concluded.

Dr. C. Alexander Hellwig, Frankfort-am-Main, Germany (in St. Cloud temporarily), presented a paper entitled: "Anesthesia in Goiter Operations at the Schmieden Clinic."

The Surgical Section then adjourned at 12:30.

MEDICAL SECTION

FRIDAY MORNING, OCTOBER 10th

E. L. Tuohy, M.D., Chairman

Chas. N. Hensel, M.D., Secretary

THE CHAIRMAN (Dr. Tuohy): The first paper this morning is by Dr. T. B. Tuttle, of the Veterans' Bureau, on the subject of Amebiasis. This is a very splendid contribution to this section and I would suggest that in discussing this you will remember that the benefit to be derived from this paper must be twofold. It must be not only what is communicated to you men who are here today, but the discussion should be in such form that the reporter may take it down in order that it may be published. There are many points of very great practical interest here, because most of us have not had our attention drawn to this matter and do not make proper stool examinations—do not attempt to properly differentiate the symptoms the patient has—and there is much obscurity as to treatment. Therefore, in opening the discussion, if you will have this point in mind we will be able to have a very good report of the benefits to be derived from this paper. I will call upon Dr. Tuttle.

Dr. Tuttle's paper entitled "Amebiasis" was discussed by Dr. Oriana McDaniel, Minneapolis; Dr. L. W. Pollock, Rochester; Dr. S. Marx White, Minneapolis; Dr. Moses Barron, Minneapolis; and in closing by the essayist.

DR. TUOHY (Chairman): Those who discuss the papers read here will get back a transcript of what they are presumed to have said. I noticed when Dr. Pollock was talking his words did not come over here very good. Let me urge you to do this when your reports come back; make an effort to bring into the report of the paper that which is actually occurring here.

I must tell you of a reporter who once reported a public man of very great prominence, whose words had great effect on the community as a whole. The reporter late in the evening, after a pre-Volstead bibulous dinner, awakened this chap, and indeed it was very early in the morning, and said:

"Perhaps you would like to have me read to you the report I made of your speech, because this is going forth and I thought it might be a courtesy to you to see it," and the man got out of bed and began to read what he had said, and he said:

"My God, man! This is awful. This is what I said," and he forthwith put down a very stirring and lucid statement, and as the reporter left the room he said: "Young man, I want to give you some advice. Never presume as long as you live to report a public man when you are drunk." This does not apply to our reporter that is here today. This is for the edification of those who wish to have a correct report go forth of what is being reported from this meeting. We have splendid discussions, but they don't always come back in good shape from the wash.

We will next listen to a paper by Dr. H. Z. Giffin, of Rochester, on the subject of "Hemorrhagic Pupura."

Those who discussed Dr. Giffin's paper were Dr. S. Marx White, Minneapolis; Dr. J. P. Schneider, Minneapolis; Dr. T. H. Sweetser, Minneapolis; Dr. Moses Barron, Minneapolis; and in closing by Dr. Giffin.

Dr. Ball read an essay entitled "Some Observations Concerning Tic Douloureux After Sixteen Years' Experience," which was discussed by Dr. A. S. Hamilton, Minneapolis;

Dr. J. C. Michael, Minneapolis; Dr. J. P. Schneider, Minneapolis; and in closing by the essayist.

Dr. W. H. Hengstler, St. Paul, presented a paper on the subject of "The Role of Infections in Nervous Disease," which was discussed by Dr. Henry W. Woltmann, Rochester; Dr. A. S. Hamilton, Minneapolis; Dr. Hengstler, in closing.

Dr. A. E. Flagstad, St. Paul, presented a paper entitled "Diathermy in Vascular Circulatory Disturbances and Arthritis." This paper was discussed by Dr. P. G. Boman, Duluth; Dr. G. S. Wattam, Warren; Dr. A. U. Desjardins, Rochester; Dr. J. C. Boehm, St. Cloud.

Dr. Paul O'Leary, Rochester, presented a paper entitled "Cutaneous Picture of Late Syphilis," which was discussed by Dr. S. Sweitzer, Minneapolis, and Dr. J. C. Michael, Minneapolis.

DR. TUOHY (Chairman): Two men on the program do not get a fair deal; those who give the first papers in the medical and surgical sections, and particularly those men on the last part of the program, and so upon an occasion like this the whole-hearted sympathy goes forth to Dr. Barron, who gives his time to the preparation of a paper of this kind and comes into the meeting at the close. I take full credit for being responsible, but as we go over the morning session it seems a crime to stop these discussions, and no man is better fitted to accept this position on the program and maintain his dignity than Dr. Barron. We will call on him to come forth and make it snappy.

Dr. Moses Barron, Minneapolis, presented his paper entitled "Diseases of the Pancreas."

DR. HEAD: Mr. Chairman, while I have many notes of interest and importance that I might bring forward, I will resign my time in this discussion to some of the other men who have something interesting to discuss.

DR. TUOHY (Chairman): Will you submit the discussion in writing and send it in?

DR. HEAD (Minneapolis): I will be glad to.

DR. CROSS (Minneapolis): It is late, Mr. Chairman. I think it is very unfortunate. We will, of course, write a discussion later. If there was time I would like to detail some cases, but I think I will forego that and write my discussion also. It is so late, and we all want to get away.

DR. TUOHY (Chairman): Will you write them out? I think that is the better suggestion. You are all uneasy. Let the gentlemen write them out and let them be incorporated in the publication.

I thank you for your patience in remaining. We are all off to luncheon, and then for the General Session at two o'clock.

The section adjourned.

GENERAL SESSION

FRIDAY AFTERNOON, OCTOBER 10th

The convention met in general session in the Sherman Theatre at 2:25 P. M., Friday, with Dr. H. M. Workman in the chair.

THE CHAIRMAN: This is the first time in my experience of forty years that the President of the Minnesota State Medical Association has not been able to be present to preside at the convention. The job has been passed on in the manner of "Let George do it," so it has been up to the President of the Council to open this session. I will therefore

called on Dr. Drake to read the Report of the House of Delegates.

THE SECRETARY: At the request of the President, Dr. Archibald MacLaren, who was unable to be here, I will read the following communication which was sent to the Association:

"It is with feelings of the deepest regret that I find it will be impossible for me to attend the meeting of the Minnesota State Medical Association at St. Cloud. Never having suffered from a severe illness before, it has seemed, from week to week, that I would surely be able to be with you at this time. In this hope, however, I am doomed to disappointment in spite of the excellent care given me by my skillful medical advisors. They assure me that before long I shall be out again and then it will be with the most heartfelt pleasure that I shall greet my old friends again. I wish to express at this time, my keenest interest in the meeting and to send to you my best wishes for its great success.

DR. ARCHIBALD MACLAREN."

The registration up to the present time is 295 out of a total membership of 1,952. This 1,952 represents a gain in membership during the past year of 68. The financial status of the Association is somewhat better than it was a year ago, the Treasurer's report showing a net gain of about \$500.

The House of Delegates met twice and the Council twice, and the following is in brief what was accomplished.

The House of Delegates recommended to the Program Committee that the next program embody more general meetings and fewer sectional meetings, and that the papers be read largely in abstract rather than have the entire paper presented, the idea being that the full paper should be published. The House of Delegates endorsed the Northwestern Health Journal, a periodical which, as you know, is for the laity.

At the request of the House of Delegates, the Council combined three committees; that is, the Cancer Committee, the Publicity Committee, and the Public Health Committee are to be amalgamated into a Public Health Committee. The question of the discontinuance of the medical defense feature of our constitution was brought up and will be voted upon at the next meeting, a year from now.

At the election of officers yesterday morning the following were elected for the calendar year 1925: President, Dr. W. L. Burnap, of Fergus Falls; First Vice President, Dr. A. S. Hamilton, of Minneapolis; Second Vice President, Dr. John Libert, of St. Cloud; Third Vice President, Dr. C. W. Moore, of Eveleth. The present Secretary and Treasurer were continued. The Councillors: First District, Dr. G. S. Wattam, of Warren; Third District, Dr. H. L. Taylor, of St. Paul; Fourth District, Dr. W. H. Condit, of Minneapolis, to succeed himself; Seventh District, Dr. F. A. Dodge, of LeSueur, to succeed himself. The Delegates to the American Medical Association: Dr. Rothrock was elected for two years, and Dr. Chapman, of Duluth, for two years. Dr. Litzenberg is the third Delegate, and he continues for another year. As Alternates: Dr. Cross, of Minneapolis, was elected for two years and Dr. Theodore Bratrud, of Warren, for two years. It was decided to hold the next meeting in Minneapolis, and tentatively the time of meeting was set by the Council as the second week of October, 1925.

THE CHAIRMAN: Is there anything further to come before this assembly? The committee appointed yesterday to present the president-elect, Dr. Wattam and Dr. Head, will present the president.

DR. WATTAM: Mr. President and Members of the Minnesota Medical Association: I have great pleasure in presenting to you Dr. W. L. Burnap, of Fergus Falls, who has been duly elected as your President and executive officer for the coming year. In selecting Dr. Burnap as your President I feel that you have done a great honor at this time to the medical profession of northwest Minnesota, and we who have known Dr. Burnap and known of the work that he has done for this Association, especially northern Minnesota, feel that you have as well honored this Association by the selection that was made by the House of Delegates yesterday. I have pleasure in presenting Dr. Burnap.

THE PRESIDENT (Dr. W. L. Burnap): Members of the Minnesota State Medical Association, Friends, Mr. Chairman: You little know the embarrassment which I feel in standing before this gathering of men, most of whom are so much more capable and worthy than I of accepting this high honor and the responsibilities of this office. It has come so unexpectedly and with at the present time such a heavy weight that I feel it impossible just now to say anything which would be of special interest or delight to you. I could not if I should try convey to you my feelings of pride and heartfelt gratification that these splendid men of northern Minnesota saw fit to present me as their representative in this Association. I will say nothing of this fine gentleman who, as I understand, made the no minuting speech. I don't like to suggest that possibly it was not entirely unselfish because he grabbed off my position of councilor as soon as I was out of the way. Nevertheless, northern Minnesota has handed this Association a package which I am sure most of you will feel is of doubtful value.

We are proud of the profession of northern Minnesota. We are proud of the advances it has made, especially during the last few years. We are proud of Duluth, our metropolis and our chief medical center. But I am glad to say that our interest does not cease there. We are proud of our University; we are proud especially of its medical department. We are proud of the accomplishments of its undergraduate and postgraduate departments; and we glory in its promise of a brilliant future. We are proud of the high character and great attainments of the profession of the Twin Cities, and I wish again at this time to extend to them our thanks for their many courtesies. We are proud and truly grateful that fate gave to Minnesota the two Mayos and permitted them to gather at Rochester the greatest group of medical authorities and specialists this world has ever known.

And so, feeling as we do, we of northern Minnesota are especially pleased that you have given us an opportunity for one year to serve the entire profession of this great state of Minnesota; and whatever the accomplishments of this year may be, the Minnesota State Medical Association can be assured that we will have given it the best that we have to give.

recognizing a simple proposition in physics, that an engine that uses all its steam in whistling has no power with which to turn the wheels, I will cut off the exhaust and proceed to work.

DR. E. L. TUOHY (as Chairman): The combined session will proceed with the program. We have the very good fortune to have with us as a guest from the Department of Zoology of the University of Chicago, Dr. Carl R. Moore. I take great pleasure in introducing Dr. Moore at this time.

Dr. Carl R. Moore, Chicago, read a paper entitled: "The Behavior of the Testes Under Varying Experimental Conditions and the Function of the Scrotum; Transplantation Cryptorchidism and Vasectomy." Dr. F. C. Rodda, Minneapolis, and Dr. C. N. Hensel, St. Paul, commented on the paper.

THE CHAIRMAN: It is my pleasant opportunity to thank the Local Committee on behalf of this Association and to express to them our very great appreciation, first for the invitation here to St. Cloud, second for the masterly way in which they have arranged their committees and have carried on this meeting, and then for the very fine comfort that we have had both as to the place of meeting and the excellent hotel accommodations, and further for the very kindly, cordial and fraternal relationship that the medical men have extended to us, and most of all the extremely cordial reception that we had from their wives and friends at the entertainment of last night. We will all go home feeling that St. Cloud is one of our very notable Minnesota centers and that we will hope to come back again. I am not sure what the precedent is on an occasion like this, but I believe a motion to carry such a resolution would be in order.

DR. J. G. C. : I move that the assembly by a rising vote attempt in that way to thank the profession of St. Cloud for their entertainment of this year.

(Motion seconded and carried.)

Dr. Lawson G. Lowrey, Minneapolis, read a paper on "Child Guidance."

Dr. O. W. Rowe, Duluth, presented a paper on "Routine Examination of the New Born," which was discussed by Drs. F. C. Rodda, Minneapolis; W. R. Ramsey, St. Paul; August Kuhlmann, Melrose; and in closing by Dr. Rowe.

Dr. Albert G. Schulze, St. Paul, read a paper entitled: "Differential Diagnosis of the Preeclamptic Toxemias and Nephritic Toxemias of Pregnancy," which Dr. W. A. Coventry, Duluth, discussed.

Dr. Henry Wireman Cook, Minneapolis, presented his paper on "Periodic Physical Examinations" very briefly, the hour being late.

THE CHAIRMAN: I feel that this subject that Dr. Cook has brought before you briefly today without sufficient audience is of great importance, and I hope that with the publication of this paper interest will be awakened and a greater opportunity for the presentation of this subject before a larger audience will be had next year. I feel that those of you who have had the courage to stay through this program and thus show your interest should have the appreciation of the chairman of this section, and that those of the essayists who had to stay and bear the brunt of the dwindling audience likewise owe the appreciation of the chairman.

This concludes the afternoon's program. The health movie has not arrived. With your permission the annual meeting of the Minnesota State Medical Association stands adjourned.

Adjournment.
